4	Further information to permit a decision to be made, or to support a review of the conditions and restrictions associated with the proposed inclusion in Annex I		253

LEVEL 1

Flupyradifurone

STATEMENT OF THE SUBJECT MATTER AND PURPOSE OF THE MONOGRAPH

1 Statement of subject matter and purpose for which the monograph was prepared

1.1 Purpose for which the monograph was prepared

The monograph for the active substance flupyradifurone and the formulated product Sivanto (plus suffix) was prepared for evaluation under Regulation (EC) No 1107/2009 to support the approval of the new active substance.

1.2 Summary and assessment of information relating to the collective provision of dossiers

Bayer CropScience AG is the sole notifier for flupyradifurone. The question of steps taken to collectively present the dossier does therefore not arise.

1.3 Identity of the active substance (Annex IIA 1)

1.3.1 Name and address of applicant(s) for inclusion of the active substance in Annex I (Annex IIA 1.1)

Applicant:
Bayer CropScience AG
Alfred-Nobel-Strasse 50
40789 Monheim
Germany

Contact person :
[redacted]
BCS-D-Global Regulatory Affairs
Tel. ++49-2173-[redacted] (office)
Fax ++49 2173-383580
e-mail: [redacted]@bayer.com

1.3.2 Common name and synonyms (Annex IIA 1.3)

Flupyradifurone (ISO), no synonyms

1.3.3 Chemical name (Annex IIA 1.4)

IUPAC: 4-[(6-chloro-3-pyridylmethyl)(2,2-difluoroethyl)amino]furan- 2(5H)-one

CA name: 2(5H)-furanone, 4-[[(6-chloro-3-pyridinyl)methyl](2,2- difluoroethyl)amino]-

1.3.4 Manufacturer's development code number (Annex IIA 1.5)

BYI 02960 (applicant's code number)

1.3.5 CAS, EEC and CIPAC numbers (Annex IIA 1.6)

CAS number:	951659-40-8
EU index number:	not allocated
EC (EINECS/ELINCS):	not allocated
CIPAC number:	not allocated

1.3.6 Molecular and structural formulae, molecular mass (Annex IIA 1.7)

Molecular formula: C12 H10Cl F2 N2 O2
Structural formula:

Molecular mass: 288.68 g/mol

1.3.7 Manufacturer or manufacturers of the active substance (Annex IIA 1.2)

Please refer to the confidential annex C (volume 4).

1.3.8 Method or methods of manufacture (Annex IIA 1.8)

Please refer to the confidential annex C (volume 4).

1.3.9 Specification of purity of the active substance (Annex IIA 1.9)

Minimum purity: 960 g/kg

1.3.10 Identity of isomers, impurities and additives (Annex IIA 1.10)

Please refer to the confidential annex C (volume 4).

1.3.11 Analytical profile of batches (Annex IIA 1.11)

Please refer to the confidential annex C (volume 4).

1.4 Identity of the plant protection product(s) (Annex IIA 3.1; IIIA 1)

1.4.1 Current, former and proposed trade names and development code numbers (Annex IIIA 1.3)

Trade name or proposed trade name:

Sivanto plus suffix

Manufacturers code number(s):
Flupyradifurone SL 200 (200 g/L)
BYI 2960 SL 200 G (chemical internal code)
79718845 (material No.)
0113814-001 (internal code)

102000021884-03 (specification and version No.)

1.4.2 Manufacturer or manufacturers of the plant protection product (Annex IIIA 1.2)

Please refer to the confidential annex C (volume 4).

1.4.3 Type of the preparation and code (Annex IIIA 1.5)

Soluble concentrate; code: SL

1.4.4 Function (Annex IIA 3.1; Annex IIIA 1.6)

Insecticide

1.4.5 Composition of the preparation (III 1.4)

Please refer to the confidential annex C (volume 4).

1.5 Uses of the plant protection product(s) (Annex IIA 3.2 to 3.4; Annex IIIA 3.1 to 3.7, 3.9 and 12.1)

1.5.1 Field of use (Annex IIA 3.3; Annex IIIA 3.1)

Intended for agricultural use as an insecticide.

1.5.2 Effects on harmful organisms (Annex IIA 3.2; Annex IIIA 3.2)

Flupyradifurone interacts with insect nicotinic acetylcholine receptors, a class of neurotransmitter-gated cation channels which are involved in excitatory neurotransmission, a target also known for neonicotinoid insecticides. Blockage of these receptors leads to paralysis and death of the target insects.

1.5.3 Summary of intended uses applied for (Annex IIA 3.4; Annex IIIA 3.3 to 3.7, 3.9)

Crop and/ or situation (a)	Country	Product Name	F G or I (b)	Pests or Group of pests controlled (c)	Formulation		Application				Application rate per treatment			PHI (days) (l)	Remarks: (m)
					Type (d-f)	Conc. of as (i)	method kind (f-h)	growth stage & season (j)	number min max (k)	interval between applications (min)	kg as/hL min max	water L/ha min max	kg as/ha min max		
Hops	N-EU (residue zone)	Sivanto	F	Aphids, *Phorodon humuli,*	SL	200	spray	BBCH 31-75 May July.	1	n.a.	0,0045-0,0075	2000-3300	0.150	21	~~Biannual~~ biennial application proposed
Lettuce	N/S-EU (residue zone)	Sivanto	F	Aphids, *Nasonovia ribisnigri*	SL	200	spray	BBCH 12-49 May--Oct	1	n.a.	0,0125-0,0250	500-1000	0.125	10	Max 1 application per **24** months
Lettuce	N/S-EU (residue zone)	Sivanto	F	Aphids, *Nasonovia ribisnigr*	SL	200	spray	BBCH 41-49 May--Oct	1	n.a.	0,0125-0,0250	500-1000	0.125	3	Max 1 application per **12** months
Lettuce (soil bound)	N-EU S-EU (residue zone)	Sivanto	G	Aphids, *Nasonovia ribisnigri,*	SL	200	spray	BBCH 12-49	2	10	0,0125-0,0250	500-1000	0.125	3	Max 2 applications per 12 months

Remarks:
a) in case of group of crops the Codex classification should be used
b) Outdoor of field use (F), or glasshouse application (G)
c) e.g. biting and sucking in insects, soil born insects, foliar fungi
d) e.g. wettable powder (WP), emulsifiable concentration (EC), granule (GR)
e) Use CIPAC/FAO Codes where appropriate
f) All abbreviations used must be explained
g) Method, e.g. high volume spraying, low volume spraying, spreading, dusting, drench
h) Kind, e.g. overall, broadcast aerial spraying, row, individual plant, between the plants
i) g/l or g/L
j) Growth stage at last treatment
k) The minimum and maximum number of application possible under practical conditions of use must be provided
l) PHI - Pre Harvest Interval
m) Remarks may include: Extent of use/ economic importance/restrictions

1.5.4 Information on authorisation in EU Member States (IIIA 12.1)

Flupyradifurone is a new active substance. No authorizations currently exist in any of the EU Member States.

LEVEL 2

Flupyradifurone

OVERALL CONCLUSIONS

2 Reasoned statement of the overall conclusions drawn by the Rapporteur Member State

2.1 Identity, physical and chemical properties, details of uses, further information, and proposed classification and labelling

2.1.1 Identity

Flupyradifurone has a minimum purity of 960 g/kg.

2.1.2 Physical and chemical properties

Flupyradifurone

Flupyradifurone is an insecticide. Its vapour pressure and volatility are very low. The solubility in water is about 3.2 g/L at a range of pH between 4 and 9. With a log Pow of 1.2 it has no bioaccumulative potential in lipophilic matrices. Flupyradifurone is hydrolytically stable under acidic, neutral and under alkaline conditions at ambient temperature. The hydrolytic degradation is negligible under acidic, neutral and alkaline conditions. Flupyradifurone is rather susceptible for reactions with hydroxyl radicals with photochemical degradation process to contribute significantly to the overall degradation of the substance in case of its occurrence in the atmosphere.
Its flammability, explosive and oxidizing properties are not critical.

Representative product

Flupyradifurone (BYI 2960) SL 200(200 g/L) is not explosive and has no oxidizing properties. Its pH is within the range that naturally occurs *e.g.* in soil. Its stability allows storage under practical and commercial conditions. Its technical properties indicate that no particular problems have to be expected, when it is used as recommended. The shelf life is 2 years in HDPE and shows no degradation.

2.1.3 Details of uses and further information

The representative formulation of Flupyradifurone is Sivanto SL 200 g/L, (orflupyradifuone SL200), it is a soluble concentrate (SL) containing 200 grams per litre (g/L) of Flupyradifurone. Respresentative uses are control of lettuce aphid (*Nasonovia ribisnigri*) in lettuce and hop aphid (*Phorodon humili*) in hop.

Flupyradifurone interacts with insect nicotinic acetylcholine receptors, a class of neurotransmitter-gated cation channels which are involved in excitatory neurotransmission, a target also known for neonicotinoid insecticides. Blockage of these receptors leads to paralysis and death of the target insects.

After uptake into the plant, Flupyradifurone is translocated acropetally in the xylem, in direction of the transpiration stream and is translaminarily distributed into adjacent plant cells.

2.1.4 Classification and labelling

Classification and labelling for the active substance

Physical and chemical properties

No classification is required.

Human health effects

Flupyradifurone (BYI 02960) needs to be classified as Acute oral toxic Cat. 4 H302 according to Regulation (EC) 1272/2008. Flupyradifurone does not need to be classified on the basis of its acute dermal, and inhalation toxicology in rats (Category 5/ Unclassified). Flupyradifurone is considered not irritating to skin and eyes (Category 5/ Unclassified). Flupyradifurone does not have sensitising properties in a LLNA (Category 5/ Unclassified).

Ecotoxicological properties

Category:	Acute 1 and Chronic 1
GHS picogram:	GHS09
Signal word:	Warning
Hazard statement:	H400 “Very toxic to aquatic life”
	H410 “Very toxic to aquatic life with long lasting effects “
Precautionary statements:	(the following may be considered):
	P273 “ Avoid release to the environment”,
	P391 “ Collect spillage”
	P 501 “ Dispose of contents/container to … [in accordance with national/international regulations (to be specified)].

Explanation:

The standard species fish, daphnids and algae are not sensitive to flupyradifurone (L/EC50 >70 mg/L). However, aquatic insects are much more sensitive. The classification is based on the lowest acute L/EC_{50} of flupyradifurone, which is <1 mg/L (*C.riparius* EC50 = 0.0617 mg/L). Therefore, flupyradifurone is classified in Category Acute 1.

Flupyradifurone is considered not ready biodegradable (see LoE fate and behaviour). There are adequate chronic toxicity data available. The NOECs for fish and daphnids are >1 mg/L, but as said above, daphnids are not sensitive to flupyradifurone and it is therefore necessary to take into account

other, sensitive, species. The lowest NOEC is <0.1 mg/L (0.010 mg/L for *C. riparius*). Therefore, flupyradifurone is classified in Category Chronic 1.

The M-factor for flupyradifurone is 10 based on both acute and chronic toxicity.

The precautionary statements may be chosen according to national regulations.

Classification and labelling for the plant protection product

Physical and chemical properties

No classification is required.

Human health effects

The formulation BYI 02960 SL 200 g/L does not need to be classified on the basis of its acute oral, dermal toxicology. According to Regulation (EC) 1272/2008 formulation BYI 02960 SL 200 g/L is classified with H332, Harmful if inhaled (R20, Harmful by inhalation according to Directive 67/548/EEC). BYI 02960 SL 200 g/L is considered not irritating to skin and eyes.
BYI 02960 SL 200 g/L has sensitising properties in a LLNA and is classified with H317 (may cause an allergic skin reaction)/R43 (may cause sensitization by skin contact).

Ecotoxicological properties

Category:	Acute 1 and Chronic 1
GHS picogram:	GHS09
Signal word:	Warning
Hazard statement:	H400 “Very toxic to aquatic life”
	H410 “Very toxic to aquatic life with long lasting effects “
Precautionary statements:	(the following may be considered):
	P273 “ Avoid release to the environment”,
	P391 “ Collect spillage”
	P 501 “ Dispose of contents/container to … [in accordance with national/international regulations (to be specified)].

Explanation:

Toxicity studies with the preparation on the standard species fish, daphnids and algae are available and it is clear that these species are not sensitive to Sivanto (BYI 02960 SL 200) (L/EC50 >100 mg formulation/L). However, aquatic insects are much more sensitive to the a.s.. There is only a chronic study available on aquatic insects for the preparation but not an acute one. Therefore, it would underestimate the acute toxicity to base the classification of the preparation on the available studies.

Instead, the acute classification is based on the summation method. Flupyradifurone is classified as H400 based on its lowest acute L/EC_{50}, which is 0.0617 mg/L, and has an M-factor of 10. The concentration of flupyradifure in the preparation (ca.20%) multiplied by the M-factor (10) is greater than 25%. Therefore, the preparation is also classified in Category Acute 1 (H400). Since this is the worst-case acute classification, the other components of the product do not need to be discussed.
The lowest chronic NOEC for the preparation is ca. 0.06 mg preparation/L (for *C. riparius)*. Therefore, the preparation is classified in Category Chronic 1 (with H410).
The precautionary statements may be chosen according to national regulations.

2.2 Methods of analysis

Analytical methods for analysis of the active substance as manufactured
The HPLC-method AM008809MP1 for the determination of Flupyradifurone (BYI 02960) in technical grade active substance can be used for determination of Flupyradifurone.

Analytical methods for formulation analysis
The HPLC method AM012609MF1for the determination of Flupyradifurone (BYI 2960) can be used for determination of flypyradifurone in the formulation Flupyradifurone (BYI 2960) SL 200.

Analytical methods for residue analysis
The submitted methods are suitbale of monitoring in the relevant matrices.

Residues in body fluids and tissues
A method of analysis for body fluids and tissues is not required, since the active substance is of low acute toxicity (GHS category 4).

2.3 Impact on human and animal health

2.3.1 Effects having relevance to human and animal health arising from exposure to the active substance or to impurities contained in the active substance or to their transformation products

2.3.1.1 Toxicokinetics

Absorption, distribution, excretion and metabolism of flupyradifurone was investigated using three different labelling positions. The active substance was labelled with ^{14}C in the pyridinylmethylene bridge, in the 4-position of the furanone ring and in the 1-position of the ethyl side chain:

Pyridinylmethyl-^{14}C flupyradifurone | Furanone-4-^{14}C flupyradifurone | Ethyl-1-^{14}C flupyradifurone

The pyridinylmethyl-labelled compound was used in an ADME-study in which male and female rats were orally administered with a single low dose of 2 mg/kg bw or a high dose of 200 mg/kg bw. Due to the high water solubility of flupyradifurone, male rats were also given an intravenous dose of 2 mg/kg bw. In this study, the excretion via urine and faeces was investigated as well as the distribution in the plasma and the radioactivity concentration in organs and tissues at sacrifice. The metabolism was investigated in urine and faeces.

A quantitative whole body autoradiography study was conducted also using the pyridinylmethyl-labelled compound following a single oral dose of 5 mg/kg bw to male and female rats. In this study the excretion of radioactivity was determined in urine, faeces and expired air, as well as the distribution in the plasma and the radioactivity concentration in the organs and tissues at various time points.

The furanone-4-labelled compound was used in an ADME-study in which male and female rats were orally administered with a single dose of 2 mg/kg bw. In this study, the excretion via urine and faeces was investigated as well as the distribution in the plasma and the radioactivity concentration in the organs and tissues at sacrifice. The metabolism was investigated in urine and faeces.

A quantitative whole body autoradiography study was also conducted using the furanone-4-labelled compound following a single oral dose of 5 mg/kg bw to male and female rats. In this study the excretion of radioactivity was determined in urine, faeces and the expired air as well as the distribution in the plasma and the radioactivity concentration in the organs and tissues at various time points.

In an organ metabolism study, male and female rats were orally administered with a single dose of 3 mg/kg bw [furanone-4-^{14}C] flupyradifurone. Animals were sacrificed 6 hours after dosage and the metabolism was investigated in urine, plasma, and in extracts of liver, kidney, muscle and fat tissues.

The ethyl-1-labelled compound was used in an ADME-study in which male rats were orally administered with 2 mg/kg bw. In this study, the excretion via urine, faeces and expired air was investigated as well as the distribution in the plasma and the radioactivity concentration in the organs and tissues at sacrifice. The metabolism was investigated in urine and faeces.

In an organ metabolism study, male and female rats were orally administered with a single dose of 3 mg/kg bw [ethyl-1-^{14}C] flupyradifurone. The animals were sacrificed at 1, 6 or 24 hours after dosing. The total radioactivity was determined over the different time periods in urine, while in plasma, liver, kidney, muscle and fat tissue at different time points after sacrifice. The metabolism was investigated in urine, plasma, and in extracts of liver, kidney, muscle, and fat tissue.

Absorption

Following oral administration of a single low dose of flupyradifurone to male and female rats, the gastrointestinal absorption of radioactivity was high. It accounted for >80 % of the dose independent of the labelling position used. The value of >80% can be used for further toxicological risk assessment.

Distribution

The maximum plasma concentration was reached in most cases within 1 or 2 hours after administration of low doses. Only after administration of the high dose of 100 mg/kg bw the peak plasma concentration was observed between 2 and 4 hours after dosage. After reaching the peak concentration, the radioactivity levels in plasma declined steadily by several orders of magnitude in all studies independent of sex or labelling position of the test compound.

Quantitative whole body autoradiography revealed a fast absorption and distribution of the test compound with peak values observed already 1 hour after administration. At this time, the concentrations in liver and kidney were significantly higher than in blood, suggesting a preferred clearance from blood and distribution mainly to these organs which are mainly responsible for metabolism (liver) and excretion (kidney). Higher concentrations than in blood were also detected in the myocardium (heart) and in several glands. Very low levels were found in the brain, spinal cord and renal fat tissue. These results were similar in male and female rats, and independent of the labelling position of the test compound.

Excretion

Excretion was very fast, mainly renal and almost completed after 24 hours. No radioactivity was detected in the expired air after dosing of the pyridinylmethyl- and ethyl-1-labelled compounds, proving

the stability of these labelling positions in the molecule. Only after administration of [furanone-4-^{14}C] flupyradifurone between 1% and 3% of the administered radioactivity was exhaled. This demonstrated that for a small portion of the dose (higher in male than in female rats) the furanone ring of the molecule obviously was opened and was subject of biotransformation to C-1 fragments.
A fast decline of radioactivity concentrations was observed for all organs and tissues in male and female rats during the entire test period. Concentrations fell for most organs and tissues below 5% of the maximum concentration after one day. After seven days, only very low concentrations were found in a few organs and tissues of rats dosed with the pyridinylmethyl-labelled test compound. In the study using the furanone-4-labelled compound, low radioactive residues were measured in almost all organs and tissues due to the incorporation of C1- or C2-fragments into the endogenous carbon pool. The residues in male rats were higher by a factor of 1.4 to 4.7 as compared to female rats. A similar ratio of approximately 3 (male/female) was also found for the formation of $^{14}CO_2$, and originates presumably from sex related differences in metabolism leading to more C1- and C2-fragments and also higher incorporation of these components into the endogenous carbon pool in male rats. In general males and female rats exhibited very similar absorption, distribution and excretion behaviour. The results of these studies demonstrate that there is no indication of any accumulation or significant retention of radioactivity in male and female rats. This observation is supported by the low P_{OW} of 1.2.
Concentrations of radioactivity detected in tissues and organs at sacrifice were either very low or below the limit of detection

Metabolism

Flupyradifurone was intensively metabolised in the rat. Numerous metabolites were formed, most of them being minor ones. The parent compound represented the predominant part of the radioactivity in urine of male and female rats. In faeces of male rats, the metabolite BYI 02960-OH was more prominent than the parent compound. Two metabolites, BYI 02960-6-CNA and BYI 02960-hippuric acid were also prominent in male but not in females rats. The organ metabolism study using the ethyl-1-^{14}C label showed that in the 24 hours samples of plasma, and organs and tissues BYI 02960-DFA was by far the dominating metabolite accounting for more than 50% of the radioactivity. In general, the metabolic profiles in urine and faeces were very similar for both sexes but male rats showed a higher rate of metabolite formation as compared to female rats. 6-CNA is considered a major metabolite in male rat but not in females.

The principal metabolic reactions of flupyradifurone in rats were:

- Hydroxylation followed by conjugation with glucuronic acid or sulfate,
- cleavage of the difluoroethyl group forming BYI 02960-des-difluoroethyl, and difluoroacetic acid (BYI 02960-DFA),

- cleavage of the molecule at the pyridinylmethylene bridge forming BYI 02960-6-CNA, which was further conjugated with glycine to BYI 02960-hippuric acid and BYI 02960-difluoroethyl-amino-furanone.
- The figure below schematically shows the sites of the molecule, which are involved in the metabolic reactions:

Summarizing, the results of the metabolism studies conducted in the rat, a proposed metabolic pathway of flupyradifurone can be described as shown in this figure:

2.3.1.2 Toxicodynamics

Acute toxicity

Flupyradifurone (BYI 02960) needs to be classified as Acute oral toxic Cat. 4 H302 according to Regulation (EC) 1272/2008. Flupyradifurone does not need to be classified on the basis of its acute dermal, and inhalation toxicology in rats (Category 5/ Unclassified). Flupyradifurone is considered not irritating to skin and eyes (Category 5/ Unclassified). Flupyradifurone does not have sensitising properties in a LLNA (Category 5/ Unclassified).

Table 6.11.2-1 Classification

Type of study	Species	Results	Classification (proposed)
Oral route	Rat	Mortalities observed at 2000 mg/kg; none at 300 mg/kg	Category 4 H302 (LD_{50} cut off >300-2000 mg/kg)
Dermal route	Rat	LD_{50} > 2 000 mg/kg	Category 5 / Unclassified
Inhalation	Rat	LC_{50} at 4 hours > >4.7 mg/L (nose only) ~~4671 mg/m^3~~	Category 5 / Unclassified
Primary skin irritation	Rabbit	Non irritating	Category 5 / Unclassified

Eye irritation	Rabbit	Slight redness of the conjunctivae, reversed within 48 hours	Category 5 / Unclassified
Skin sensitization	Mouse	Not sensitizing	Category 5 / Unclassified

Short-term toxicity

Oral

Four subacute oral range-finding studies were performed, with rat, mouse and dog.

In a 28-day study with rats exposed to 0, 75, 200 or 350 mg/kg bw/d via gavage, toxicologically relevant effects were clinical chemical findings, increased organ weights and pathological findings in the 200 mg/kg bw/d group. The NOAEL in this study is set at 75 mg/kg bw/d.

In a 28-day study with rats exposed to 0, 33.6 or 385 mg/kg bw/d via diet, toxicologically relevant effects were clinical chemical findings, increased liver and thyroid weights and associated pathological findings in the 385 mg/kg bw/d group. The NOAEL in this study is set at 33.6 mg/kg bw/d.

In a 28-day study with mouse exposed to 300, 600 and 1200 ppm (equating approximately to 50, 98 and 207 mg/kg bw/day in males and 59, 122, 240 mg/kg bw/day in females) via diet, no toxicologically relevant effects were observed. ~~Given the instability of BYI 02960 in rodent diet the actual concentration is considered to be in the region of 960 to 1080 ppm (166 to 186 mg/kg body weight/day for the males and 192 to 216 mg/kg body weight/day for the females, respectively).~~ The NOAEL in this study is set at 98 ~~166~~ ~~33.6~~ mg/kg bw/d.

In a 28-day study with dogs exposed to 0, 500, 2000 or 4000 ppm (equating approximately to 0, 16, 62, 118 mg/kg body weight/day in males and 0, 18, 77, 131 mg/kg body weight/day in females) via diet, toxicologically relevant effects were body weight loss and reduced body weight gain at the 4000 ppm group. The NOAEL in this study is set at 2000 ppm (62 mg/kg bw/d).

Four semichronic oral studies were performed, with rat, mouse and dog.

In a 90-day toxicity study with rat exposed to 0, 100, 500, 2500 ppm (equating to approximately 0, 6.0, 30.2, 156 mg/kg bw/day in males and 0, 7.6, 38.3, 186 mg/kg bw/day in females) via diet, toxicologically relevant effects were clinical chemical findings, increased relative liver and thyroid weight and associated pathological findings in the 2500 ppm group, and thyroid weight effects in the 500 ppm males. The NOAEL in this study is 100 ~~500~~ ppm (6.0 ~~30.2~~ mg/kg bw/d).

In a 90-day toxicity study with mouse exposed to 0, 100, 500, 2500 ppm (equating approximately to 0, 16, 81, 407 mg/kg bw/day in males and 0, 19, 98, 473 mg/kg bw/day in females) via diet, toxicologically relevant effects were clinical chemical findings, increased relative liver and decreased kidney weights and associated pathological findings in the 2500 ppm group. The NOAEL in this study is 500 ppm (81~~80.6~~ mg/kg bw/d).

In a 90-day toxicity study with dog exposed to 0, 400, 1200 or 3600/2400 ppm (equating approximately to 0, 12, 33 and 102/85 mg/kg bw/ day for males and 0, 12, 41 and 107/78 mg/kg bw/day for females) via diet, toxicologically relevant effects were reduced body weight, reduced body

weight gain, clinical chemistry, significant increase in kidney weight and focal myofiber atrophy/degeneration in the 1200 ppm group. The NOAEL in this study is 400 ppm (12 mg/kg bw/d).
In a 1-year toxicity study with dog exposed to 0, 150, 300 and 1000 ppm (equating approximately to 0, 4.6, 7.8 and 28.1 mg/kg bwd/day for males and 0, 4.1, 7.8 and 28.2 mg/kg bw/day for females) via diet, toxicologically relevant effects were micropathology (degeneration of the skeletal muscle (*gastrocnemius* and *biceps femoris* (atrophy, necrosis and/or presence of inflammatory cells)) findings in the 1000 ppm group. The NOAEL in this study is 300 ppm (7.8 mg/kg bw/d).

Dermal

Male and female rats, 10 rats/sex/group (one control and three test substance-dosed groups) were administered BYI 02960 (50, 150, or 500 mg/kg/day) daily by dermal application for at least 28 consecutive days (minimum of 6 h/day) and euthanized one day following the last dose. Based on the lack of adverse findings observed in the study, the 28-day dermal exposure NOAEL in male and female rats dosed with BYI 02960 was 500 mg/kg bw/day.

Genotoxicity

BYI 02960 was not mutagenic in two Ames tests.
BYI 02960 did not induce structural chromosome aberrations in V79 cells when tested up to and including cytotoxic concentrations and showed no mutagenic potency in vitro in the CHO/HPRT assay.
BYI 02960 did not induce micronuclei in mouse bone marrow cells in two separate in vivo studies.
Overall it can be concluded that BYI 02960 has no mutagenic or clastogenic potential.

Long-term toxicity and carcinogenicity

In a two-year toxicity/carcinogenicity study with rats, effects in the liver and in a less extend in the thyroid and lung (females) were observed in the 2000 ppm dose group. The NOAEL for general toxicity was set at 400 ppm in diet, equal to the average daily intake of 15.8 mg/kg bw/d. No neoplastic lesions were observed in the study at any dose level.
In an 18-months carcinogenicity study with mice, effects in the liver and in de kidney (male) were observed in the 1500 ppm dose group. The NOAEL for general toxicity was set at 300 ppm equal to the average daily intake of 45 mg/kg bw/day. The NOAEL for carcinogenicity was set at the highest dose level of 1500 ppm, equal to the average daily intake of 224 and 263 mg/kg bw/day over 18 months for male and female mice, respectively.

Reproductive and developmental toxicity

In the rangefinder one generation rat reproduction study, BYI 02960 was administered continuously in the feed to Wistar rats (10 animals/dose/sex) at nominal dietary concentrations of 0, 200, 700, and 2000 ppm. The parental systemic LOAEL is 700 ppm (60.0 mg/kg bw/day females), based on

decreased body weight, decreased body weight gain, alterations in food consumption during premating, and decreased spleen weights in females. The parental systemic NOAEL is 200 ppm (17.5 mg/kg bw/day).
The reproductive NOAEL is 147.5 mg/kg bw/day based on no reproductive findings observed at the highest dose tested.
The offspring LOAEL is 700 ppm (60.9 mg/kg bw/day). The LOAEL is based on maternal effects leading to secondarily-mediated effects on pup weight, pup weight gain, and organ weight changes (brain). The offspring NOAEL is 200 ppm (17.5 mg/kg bw/day).

A significant decrease in body weight, but <10% was observed in the mid-dose of the F1 females and a non significant decrease in body weight gain was found in the parental animals (21 % in females) and the F1 animals (16 % in females). Therefore the parental systemic LOAEL is considered 500 ppm (32 mg/kg bw/d) based on decreased body weight gain in females. The parental systemic NOAEL is 100 ppm (6.4 ~~7.7~~ mg/kg bw/d). ~~Therefore the parental systemic LOAEL is considered 1800 ppm (117.4 mg BYI 02960/kg bw/day) based on increased liver and thyroid weights, and minimal centrilobular hypertrophy in males decreased body weight (>10%)(premating, gestation, and lactation), body weight gain (premating; P and F_1). The parental systemic NOAEL was 500 ppm (32.0 mg BYI 02960/kg bw/day).~~The reproductive NOAEL was 500 ppm (34.3 mg BYI 02960/kg bw/day females) based on decreased estrous cycle number, litter size, and the number of implants observed in the F_1 generation at the highest dietary level tested (LOAEL = 1800 ppm (134.0 mg BYI 02960/kg bw/day in females).
A significant decrease in body weight, but <10% was observed in the mid-dose of the F2 pups. The offspring LOAEL is therefore 1800 ppm (134.0 mg BYI 02960/kg bw/day) based on maternal effects leading to secondary effects on pup weight, and physical development. The offspring NOAEL is 500 ppm (34.3 mg BYI 02960/kg bw/day).

In a rat developmental study, BYI 02960 was administered daily by gavage to groups of 25 pregnant Sprague-Dawley female rats per dose-group at 15, 50 and 150 mg/kg/day from gestation day (GD) 6 to 20. Minimal maternal toxicity was observed at the high-dose level, manifested as decreased body weight gain and reduced food consumption. The mean absolute liver weight was increased in the high dose group.Based on these findings the Noael vor maternal toxicity was set at 50 mg/kg bw/day. The increased incidence of parietal incomplete ossification showed no dose response, the unossified cervical centrum and the incomplete ossification of the sternebra was within the historical background. A increase of a short costal cartilage was seen at the high-dose. Based on these findings, the NOAEL for developmental toxicity was set at 50 mg/kg bw/day.

In a complementary study, where groups of 23 sperm-positive female Sprague-Dawley rats were exposed to BYI 02960 by oral gavage from gestation day (GD) 6 to 20 at 20 and 30 mg/kg/day, no maternal toxicity was

observed up to 30 mg/kg/day. Therefore, based on these two studies, it can be concluded that the NOEL for maternal toxicity was 30 mg/kg/day.

In a rabbit developmental study, groups of 23 time-mated pregnant female New Zealand White rabbits were administered BYI 02960 by oral gavage from gestation day (GD) 6 to 28 at 7.5, 15 and 40 mg/kg/day. The effects on (corrected) body weight gain and food consumption were slight and mainly transient, however considered adverse (>10%).The NOAEL for maternal toxicity and developmental toxicity was set at 15 mg/kg bw/day.~~There were no treatment-related findings for maternal and developmental toxicity therefore the NOAEL for maternal toxicity and developmental toxicity was set at 40 mg/kg bw/day.~~

Neurotoxicity

In an acute neurotoxicity study, BYI 02960 was administered by gavage in a single dose to non-fasted young adult Wistar rats at 0, 50, 200 and 800 mg/kg. Compound-related effects were observed at all dose concentrations in both sexes. The only treatment-related effects at 50 mg/kg were limited to higher incidences of piloerection in both sexes and dilated pupils in females only. A follow-up study was performed in order to establish a clear NOAEL for findings observed at all dose levels in the initial study. In this follow-up study, females only were used as they were equal or more sensitive than males at higher dose levels and were administered BYI 02960 at 20 or 35 mg/kg. No treatment-related effects were evident at either dose tested. The dose level of 35 mg/kg of BYI 02960 was considered to be the overall NOAEL for both sexes.

In a 90-day neurotoxicity study, through approximately 13 weeks of continuous dietary exposure to BYI 02960 at 100, 500 or 2500 ppm, there were no neurotoxic treatment-related findings apparent at any dietary level in either sex. Based on these findings, a NOAEL of 2500 ppm was established for the rat (equating to 143 mg BYI 02960/kg bw/day for males). Body weight and food intake effects were seen at the highest dosage. The systemic NOAEL is therefore 29.4/34.8 mg/kg bw/d for males and females respectively.

In a developmental neurotoxicity study, dietary exposure to BYI 02960 from GD 6 through LD 21 to mated female Wistar rats resulted in treatment-related effects (maternal: decreased body weight gain. Offspring: decreased body weight gain, slightly increased in motor and locomotor activity, slightly increased auditory startle habituation) evident only at 1200 ppm (102 mg/kg bw/day) in maternal animals and offspring. ~~Therefore, the NOAEL for both maternal animals and offspring is 500 ppm (42.4 mg/kg bw/day) in this developmental neurotoxicity study.~~

The maternal NOAEL was 500 ppm (42.4 mg/kg bw/d) based on decreased body weight and body weight gain. The developmental NOAEL was 500 ppm (42.4 mg/kg bw/d) based on decreased offspring body weight and body weight gain. The developmental neurotoxicity NOAEL was 500 ppm (42.4 mg/kg bw/d) based on increased startle amplitude in females only on PND 60 and increased motor and locomotor activity on PND 13 in males only.

Further toxicological studies

Biokinetic study

Plasma concentration of BYI 02960 was assessed at three time points after continuous dietary administration for seven days. Groups of 5 male and 5 female Wistar rats received the diet admixed with the test substance at a concentration of 400 ppm (equating approximately to 22.6 mg/kg body weight/day in males and 32.4 mg/kg body weight/day in females).

During the first 15 days of acclimatization, the daily light/dark rhythm was 7 a.m. - 7 p.m. Rats being known to preferably eat during the dark period, the daily light/dark rhythm of rats was changed from November 25, 2009 (pre-study Day 16, *i.e.* 14 days prior to first day of treatment) onwards, *i.e.* dark period was from 2 a.m. to 2 p.m. and light period was from 2 p.m. to 2 a.m., in order to allow the blood sampling during the working day. Clinical signs were observed daily. Body weights were measured just prior to the start of admixed food administration (Study Day 1) and on Study Day 8. Food consumption was recorded on Study Days 1 - 4, 4 - 7 and 7 - 8.

Whole blood was collected on heparin for plasma preparation from treated animals at three time points on Study Day 8 (8 a.m., 2 p.m. and 5 p.m.). The day after the end of the treatment period, animals were sacrificed without necropsy. Dietary administration of BYI 02960 induced no mortalities or treatment-related clinical signs.

The results obtained indicated a small sex difference in the plasma concentrations of BYI 02960, values being slightly higher for females than for males.

In male rats, a Cmax of 8.3 mg/L was measured at the time of collection of 8 a.m. In female rats, a Cmax of 9.4 mg/L was measured at the time collection of 2 p.m. However, in view of the inter-individual variability, the concentrations of BYI 02960 in plasma were considered similar between the three times of blood collection for both sexes (between 7.8 and 8.3 mg/L for males and between 8.8 and 9.4 mg/L for females). In conclusion, in the environmental conditions of the long-term studies (light: 7 a.m. to 7 p.m. & dark period: 7 p.m. to 7 a.m.) and assuming that animals are starting eating food when the light is switched off, the blood collection can be performed between 1 a.m. and 10 a.m. in order to measure the maximum concentration of BYI 02960.

28-Day immunotoxicity study

BYI 02960, was administered continuously via dietary administration to separate groups of female Wistar rats (10/group) at concentrations of 125, 600 and 3000 ppm (equating approximately to 10, 50, 230 mg/kg body weight/day) for at least 28 days. BYI 02960 was considered not to have any immunotoxic potential in female Wistar rats when given in the diet at dose levels up to 3000 ppm (corresponding to approximately 230 mg/kg/day) for at least 28 days.

Toxicity of metabolites

Difluoroacetic acid (DFA, BCS-AA56716) is a major soil, water and plant metabolite of BYI 02960; in the rat ADME study, it was found in urine at around 6% of the administered dose. This metabolite is devoid of genotoxic potential; the acute oral LD50 is between 300 and 2000 mg/kg, similar to parent compound. In a 14 day repeat dietary administration range finding study in the rat, the most significant findings were decreased mean glucose concentration in both sexes and an increase in urea concentration was observed in females only. In a 90-day rat study, DFA was administered in the diet to Wistar rats (10/sex/group) at concentrations of 200, 1000 and 6000 ppm. Lower mean glucose concentrations, lower total bilirubin and slightly higher mean urea concentrations were observed in both sexes at all doses. At 6000 and 1000 ppm dose levels, mean body weight, overall body weight gain and food consumption were reduced in both sexes. Lower hemoglobin concentration and lower mean corpuscular volume were observed in females, together with lower mean corpuscular hemoglobin and lower hematocrit, and higher ketone levels were noted in both sexes. A few black foci were also noted in the glandular part of the stomach in both sexes (including one control female), in correlation with a few cases of focal glandular erosion/necrosis observed at the microscopic examination. The minor changes noted in the clinical chemistry determination at the low dose are considered not to be adverse effects of the test substance as they do not represent any functional impairment in the test organism. Therefore, the dose level of 200 ppm (equating to 12.7 and 15.6 mg/kg body weight/day in males and females, respectively) was considered to be a No Observed Adverse Effect Level (NOAEL) in the male and female Wistar rats. When the NOAEL is expressed in BYI 02960 equivalents, it equates to 38 and 47 mg/kg/day in males and females, respectively. Therefore, Difluoroacetic acid was not more toxic than BYI 02960 after subchronic administration to the rat. The metabolic changes observed with DFA are also observed with BYI 02960. The decrease in glucose was reversible and appeared to be adaptative as it was no longer significant during the second part of the rat carcinogenicity study.

BYI 02960-difluoroethyl-amino-furanone (BCS-CC98193, BYI 02960-DFEAF) is a minor plant metabolite of BYI 02960 and was also observed in the rat ADME study. It accounted for less than 10% of the administered dose in the rat urine. Since the confined rotational crop study with [furanone-4-14C]BYI 02960 indicated rather high residue levels of BYI 02960-difluoroethyl-amino-furanone in leafy crops and the absence of other suitable markers, BCS decided to include this metabolite in the residue definition for the data collection method for target and rotational crops (see residue section). The subsequent residue studies revealed that BYI 02960-difluoroethyl-amino-furanone is only a minor plant metabolite. However, based on the results of the confined rotational crop study, additional tox studies (acute toxicity testing, genotoxicity testing and subacute rat study) were conducted to show that the tox profile of the metabolite is covered by the endpoints derived from the parent compound. In the *in vitro* genotoxicity package, the Ames and HPRT tests were negative and the chromosome aberration test was positive. Therefore, two *in vivo* studies (*in vivo* micronucleus test and *in vivo* unscheduled DNA synthesis) were conducted, both of which were negative. Based upon the overall

findings, BYI 02960-difluoroethyl-amino-furanone can be considered not genotoxic. The acute oral LD_{50} in rats was higher than 2000 mg/kg. The NOAEL of the 28-day rat study was 3000 ppm equating to 243 and 273 mg/kg/day in males and females, respectively based on body weight effects.

Several toxicology studies exist for two plant metabolites BYI 02960-CHMP ((6-chloro-3-pyridyl) methanol) and BYI 02960-6-CAN (6-chloronicotinic acid), which are metabolites common to other pesticides. For BYI 02960-CHMP, the Ames test was negative. The acute oral rat LD_{50} was 1842 mg/kg in males and 1483 mg/kg in females. In a 90-day rat study, BYI 02960-CHMP administered continuously via dietary administration to Sprague Dawley rats (10/sex/group) at concentrations of 160, 800, 4000 and 20 000 ppm resulted in decreases in mean body weights and mean food consumption in both sexes and a statistically significant increases in serum alkaline phosphatase activity in the 20000 ppm group females at study termination only. Histologically, dose-related eosinophilic intranuclear inclusions were seen in the proximal tubular epithelium of kidneys for 20000 ppm males and females and 4000 ppm males. The no observed effects level (NOEL) was 800 ppm (48.9 mg/kg/day) in males, and 4000 ppm (275.9 mg/kg/day) in females. When the NOEL is expressed in BYI 02960 equivalents, it equates to 97.8 and 551.8 mg/kg/day. Therefore, BYI 02960-CHMP was less toxic than BYI 02960 after subchronic administration to the rat.

For BYI 02960-6-CAN (6-chloronicotinic acid) an acute oral rat toxicity study and an Ames test were performed for the registration of acetamiprid. BYI 02960-6-CAN was not genotoxic and not acutely toxic.

The reference values of the parent flupyradifurone are applicable to both metabolites DFA and DFEAF; the experts considered that there was sufficient evidence to conclude that DFEAF is unlikely to have genotoxic potential.

ADI

The calculation of the ADI is based on the highest dose at which no adverse effect is observed in the most appropriate study in the most sensitive species. BYI 02960 was tested in several short-term studies in dogs, rats, and mice, in long-term toxicity studies in rats and mice, and in reproduction and developmental toxicity studies in rats and rabbits, providing the basis for the establishment of the ADI. ~~The lowest NOAEL (7.8 mg/kg/day) was obtained from a 1-year study in dog. Similar critical effects (myofiber degeneration, similar number of effected animals) were seen in the 90-day study with dog. It is therefore suggested to use both the 1-year dog study and the 90-day dog study to set the NOAEL of 12 mg/kg/d used as a starting point for the establishment of the ADI, also taking into account the sufficient dose spacing between the 90-day dog NOAEL and the 1-year LOAEL. Application of a safety factor for inter- and intraspecies differences of 100 results in an ADI of 0.12 mg/kg bw/day.~~

~~The lowest NOAEL (7.7 mg/kg bw/d) was obtained from the 2-generation study in rat based on body weight effects in the parent animals. Application of a safety factor for inter- and intraspecies differences of 100 results in an ADI of 0.08 mg/kg bw/day (rounded from 0.077 mg/kg bw/day).~~

Considering the parental and offspring NOAEL in the multigeneration study, the experts agreed to set the ADI at 0.064 mg/kg bw per day, applying an uncertainty factor of 100.

ARfD (acute reference dose)

The calculation of the acute reference dose is based on the highest dose at which no adverse effect is observed in the most appropriate acute toxicity study in the most sensitive species. The maternal NOAEL of 15 mg/kg bw/d in the developmental toxicity study in rabbit is based on a reduced body

weight of 12% during the first days of treatment which is an applicable effect to set the ARfD. Application of a safety factor for inter- and intraspecies differences of 100 results in an ARfD of 0.15 mg/kg bw/d.

~~Only slight body weight gain effects were observed at the top dose in the developmental toxicity studies in both rats and rabbits. Acutely toxic effects were seen only in the acute neurotoxixity study, where typical signs of nicotinergic insecticides have been observed. Therefore, it seems appropriate to set up the ARfD using the NOAEL of the acute neurotoxicity study. Application of a safety factor for inter- and intraspecies differences of 100 results in an ARfD of 0.35 mg/kg bw.~~

AOEL

The calculation of the AOEL is based on the highest dose at which no adverse effect is observed in the most appropriate study in the most sensitive species. BYI 02960 was tested in several short-term studies in dogs, rats, and mice, in long-term toxicity studies in rats and mice, in reproduction and

developmental toxicity studies in rats and rabbits, and neuro and immuno toxicity studies with rats providing the basis for the establishment of the short-term and long-term AOEL.

The lowest NOAEL (6.4 ~~7.7~~ mg/kg bw/d) was obtained from the 2-generation studie in rat based on body weight effects in the parent animals. A correction factor for oral absorption is not necessary since the oral absorption is >80%. Application of a safety factor for inter- and intraspecies differences of 100 results in an ADI of 0.08 mg/kg bw/day (rounded from 0.077 mg/kg bw/day).

~~The lowest NOAEL (7.8 mg/kg/day) was obtained from a 1-year study in dog. Similar critical effects (myofiber degeneration, similar number of effected animals) were seen in the 90-day study with dog. It is therefore suggested to use both the 1-year dog study and the 90-day dog study to set the NOAEL of 12 mg/kg/d used as a starting point for the establishment of the AOEL, also taking into account the sufficient dose spacing between the 90-day dog NOAEL and the 1-year LOAEL. A correction factor for oral absorption is not necessary since the oral absorption is >80%. Application of a safety factor for inter- and intraspecies differences of 100 results in an AOEL of 0.12 mg/kg bw/day for both short-therm and long-therm.~~

2.3.5 Drinking water limit

According to Council Directive 97/57/EC, exposure to BYI 02960 through drinking water should account for not more than 10% of the ADI. If it is assumed that the average daily consumption of water amounts to 2 litre per person of 60 kilogram, a potential drinking water limit of ((60x0.064 ~~0.08~~ ~~0.12~~)/10)/2 mg/l, i.e.0.192 ~~0.24~~ ~~0.36~~ mg/l can be established.

According to Document 8064/VI/79 of the European Commission, the EU drinking water limit for pesticides of 0.1 µg/l is applicable for BYI 02960.

2.3.6 Impact on human or animal health arising from exposure to the active substance or to impurities contained in it

Internal exposure and risk assessment

Risk assessment for operators

Risk assessment was performed using the 75th percentile from the UK-model (UK-75th), the geometric mean from the German model (DE-GM) and the 90th percentile from the Dutch model (NL-90th).

than respiratory exposure during application.

2.4 Residues

2.4.1 Definition of the residues relevant to MRLs

Plant products

The residue definition for post-registration monitoring is proposed as: ~~the sum of~~ parent compound and DFA, expressed as DFA ~~in flupyradifurone equivalents~~, separately.

The residue definition for risk assessment is proposed the sum of parent compound flupyradifurone and its metabolites DFA ~~and difluoroethyl-amino-furanone (DFEAF)~~, expressed in flupyradifurone equivalents. ~~A conversion factor is not required to cover the difference between the residue definition for monitoring and risk assessment as both DFA and flupyradifurone are part of the residue definition for monitoring and as DFEAF is found in levels below <0.01 mg/kg in supervised residue trials and in rotational crops.~~

Animal products

The residue definition for post-registration monitoring ~~and risk assessment~~ is proposed as: ~~the sum of~~ parent compound and DFA, expressed as DFA ~~in flupyradifurone equivalents~~, separately.

The residue definition for risk assessment is proposed as: the sum of parent compound and DFA, expressed in flupyradifurone equivalents.

2.4.2 Residues relevant to consumer safety

Residues in products of plant origin

Protected Lettuce

Nine acceptable residue trials performed in accordance with the cGAP for greenhouse use have been provided. In the greenhouse trials a highest residue value (HR) of 6.04 mg/kg was determined and an the STMR of 2.12 ~~2.0~~ ~~2.2~~ mg/kg for the sum of flupyradifurone and DFA, expressed as flupyradifurone.

Unprotected Lettuce

For the envisaged outdoor use in Northern and Southern Europe with a 10d PHI the required number of trials are available (nine acceptable trials for each region).

For the envisaged agricultural outdoor use in Northern and Southern Europe with a 3d PHI, the residue trials performed with lettuce in Northern and Southern Europe are not acceptable, except for two trials with sampling 2 days after the 1st treatment. No samples were taken 3 days after the first application. However, the results from the trials performed with outdoor lettuce in Northern and Southern Europe at 3 days after the 2nd treatment were valid to determine that the intended use on protected lettuce can be identified as the worst case residue situation, based on a comparison of the

residue values from field and greenhouse testing using the most critical use pattern (2x125 g as/ha, int. 10d, PHI 3d).

Moreover, the tested GAP with two applications and a pre-harvest interval of 3 days is the "home and garden" use, which was submitted in parallel and is envisaged for registration shortly after the agricultural use (see the Evaluation Report for Flupyradifurone as an appendix to Vol. 3, B7). Since this field use is more critical than the agricultural field use, it was agreed with the RMS to conduct all field residue trials according to this GAP to identify the most critical consumer exposure and to avoid re-evaluation of MRLs due to this use. Hence, the trials in the DAR are not in accordance with the cGAP in the DAR, but with the cGAP supported in EU for MRL setting.

Thus, the open field trials in lettuce in Northern and Southern Europe are in compliance with the envisaged "home and garden" use. In addition, sufficient trials were performed providing evidence that the envisaged greenhouse can be identified as the worst case residue situation. Therefore no further trials are required.

Hops

In hops, eight valid trials were conducted in the northern European residue region in the years 2010-2011. Flupyradifurone was applied once as an SL 200 formulation at an active substance rate of 120 - 150 g/ha. All applications were at acceptable rates, and all trials were conducted according to GLP. in dried cones, residue levels also tended to decline with time. When evaluating the highest residues at relevant sampling intervals (either day 21 or, in three trials, day 28), residues ranged from 0.34-2.3 ~~0.61-2.4~~ mg/kg, with a median of 1.05 ~~1.15~~ mg/kg for the sum of flupyradifurone and DFA, expressed as flupyradifurone.

Residues in rotational crops

The metabolism of BYI 02960 residues in the rotational crops wheat (small grain), Swiss chard (leafy crop) and turnip (root crop) was investigated at a nominal application rate of 400 g a.s./ha. The plant back intervals were 29, 135 and 296 days for all crops. The studies were conducted with [furanone-4-^{14}C]BYI 02960 and [pyridinylmethyl-^{14}C]BYI 02960. A study with [ethyl-1-^{14}C]BYI 02960 was not conducted and therefore non-radiolabelled difluoroacetic acid was determined in all extracts obtained in the CRC study conducted with [furanone-4-^{14}C]BYI 02960 to gain information on the fate of the difluoroethane moiety of the active substance.

Corresponding TRR values showed similar residue levels when comparing the studies performed with [furanone-4-^{14}C]BYI 02960 and [pyridinylmethyl-^{14}C]BYI 02960. Generally, the TRR values were slightly higher in the crops of 1st and 2nd rotation of the study performed with [pyridinylmethyl-^{14}C]BYI 02960, except for wheat grains, where it was the opposite way round due to the selective transport of glucose as a label specific metabolite into the RAC.

The levels of parent compound decreased with increasing plant back intervals but nevertheless parent formed a main portion of the residues in all of the RACs in all rotations, except for wheat grains. Other major metabolites (accounting for >10% of the TRR in at least one RAC in one rotation) were

- DFA, which was the main metabolite in wheat grains (all rotations) and in turnip roots (1st rotation) and a major metabolite in all other RACs
- 6-CNA-glucerol-gluA (3 isomers), which were major in and specific for all wheat commodities and accounted in sum for 11% to 33% of the TRR considering all rotations
- BYI 02960-difluoroethyl-amino-furanone, which was a major metabolite in all Swiss chard samples in all rotations and accounted for up to 17% of the TRR
- BYI 02960-OH-glyc, which was major in Swiss chard and turnip leaves in all rotations
- BYI 02960-glyoxylic acid, which was only a major metabolite in wheat forage, hay and straw and in turnip roots of the first rotation, in subsequent rotations it was detected in minor amounts, only
- BYI 02960-bromo-amino-furanone, which was only major in wheat hay of the 3rd rotation
- BYI 02960-OH, which was major in wheat grains of the 1st rotation, only
- Glucose/carbohydrates, which were identified as the main portion in wheat grains after exhaustive extraction and as a major metabolite in turnip roots after conventional extraction.

The proposed metabolic pathway is very similar to the one of primary crops. As observed in target plants the metabolic reactions involved were hydroxylation and oxidative cleavage of the active substance followed by additional oxidation and conjugation processes. No additional metabolic routes were detected, only additional metabolites were identified, e.g. additional conjugates or existing metabolites were subjected to further oxidation reactions.

Four multi-plantback multi-crop rotational crop trials were conducted in Europe (2 each in the northern and southern residue regions) in the years 2010-2011. Flupyradifurone was applied once as an SL 200 formulation either to bare soil or to a target crop (lettuce) at an active substance rate of 200 g/ha, the target crop was then harvested, and crops representing 3 different botanical groups (roots, leafy veg., cereals) were planted on the plots at 3 intervals thereafter. All applications were at the required rates, and all trials were conducted according to GLP.

Quantifiable residues were measured in all rotations. Total residues of BYI 02960 in all rotational crops tended to be highest in the first, earliest rotation with a plant back interval of 25-33d.

Residues ranged from 0.05-0.14 mg/kg (median 0.06 mg/kg) in early harvest root crops, from 0.06-0.21 mg/kg (median 0.08 mg/kg) in early harvest leaf crops, 0.05-0.41 mg/kg (median 0.10 mg/kg) in cereal green forage, <0.07-0.39 mg/kg (median 0.12 mg/kg) in barley straw and from 0.11-0.65 mg/kg (median 0.35 mg/kg) in cereal grain grown in the first rotation, residues as the sum of flupyradifurone and DFA, expressed as flupyradifurone.

Up to the third rotation, residues above the LOQ were detected.

Additionally, field rotational crop trials were performed representative for each type of crop at short plant back intervals (PBI 30 days) and in accordance with the supported dose rate of 125 g as/ha. Potatoes, leek, cucumber, onion, bean (fresh), peas (dry) and winter rape was grown at two locations in Northern and at two locations in Southern Europe. BYI 02960 levels were always low (≤0.05 mg/kg), levels of DFEAF were always <0.01 mg/kg while soil metabolite DFA was present in all trials except in all French bean trials and one leek trial. Residues at harvest showed considerable variation which could not be attributed to geographical zone, soil type, pH, organic matter content, and temperature during treatment, rainfall after treatment or growth period (results not shown). Therefore, results for Northern and Southern Europe are considered as one data set with considerable variation.
HRs of DFA, expressed as DFA were 0.083, 0.076, 0.136, 0.053, 0.365, 0.764 and 0.05 ~~0.26, 0.24, 0.42, 0.17, 1.1, 2.3, and 0.16~~ ~~0.27, 0.25, 0.43, 0.18, 1.1, 2.3 and 0.17~~ mg/kg in potatoes, leek, cucumber, onion, bean (fresh), peas (dry) and winter rape, respectively.

Processing studies

Flupyradifurone stable under all conditions of high temperature hydrolysis for simulation of food processing. The following conditions were tested:

- pH 4 / 90°C (20 min) - pasteurisation
- pH 5 / 100°C (60 min) - baking, brewing, and boiling
- pH 6 / 120°C (20 min) - sterilisation

Metabolite DFEAF is a substructure of the parent compound. All functional groups, chemical moieties and their constitution of DFEAF are also present in the chemical structure of the parent compound. Therefore the chemical stability DFEAF is covered by studies with the parent compound. As parent compound was proved to be stable under the processing conditions, it is concluded that this is also true for DFEAF. In addition, in almost all uses worldwide – and certainly in all EU-relevant uses – DFEAF does not play any significant role in the field residues, generally comprising <5% of the total residue.
Due to the similarity of the chemical structures, the properties of DFA (= difluoroacetic acid) can be interpolated from the properties of TFA (= trifluoroacetic acid) and HOAc (acetic acid). The latter compounds are very common in organic chemistry, have often been used in chemical synthesis and many properties have been investigated. It can be deduced from literature data that these two compounds are stable under the conditions to be tested in a processing study. By interpolation of these properties, it is concluded that DFA is also stable under the processing conditions.

Household preparation of lettuce heads, i.e. removing outer leaves and washing the remaning head (separated in inner and outer head) resulted in processing factors of 1.8 for outer leaves, 0.72 ~~0.73~~ for inner head parts and 0.87 ~~0.76~~ for inner leaves.

Using hops in the production of beer, the transfer factors was determined to be 0.01. In the intermediates in the production of beer, the average processing factor was <0.1.

Residues in products of animal origin

Flupyradifurone was administered orally to laying hens for 29 consecutive days at average dose rates of 1.5 mg/kg feed (1.2N) 6.5 mg/kg feed (5.4N ~~4.3N~~ ~~4.9N~~), 19.4 mg/kg feed (16N ~~13N~~ ~~14.7N~~), and 65.1 mg/kg feed (54N ~~43N~~ ~~49N~~). After the final dose, the animals were sacrificed and the key edible tissues were analyzed for the relevant residues of flupyradifurone. The combined residues of flupyradifurone + DFA in poultry tissues at sacrifice in the 1.2N dosing group were 0.093 mg/kg in muscle, 0.039 mg/kg in fat, and 0.11 mg/kg in liver, expressed in parent compound equivalents. Prior to sacrifice, residues in eggs were measured at various intervals in the high-dose group, and on days 24 and 28 in the three lower dose groups. In the 1N dose group, residues (flupyradifurone + DFA) in eggs amounted to 0.061 and 0.057 mg/kg, respectively.

Residue analysis of the high-dose eggs showed that levels reached a plateau in eggs. Though residues were highest at day 28, residue data from the 54N ~~43N~~ ~~49N~~ egg samples, when evaluated against the dose rate increases calculated as mg a.s./kg bw, suggest that flupyradifurone residues actually reached a plateau between day 4 and day 7; increases in residue levels were only due to increased dose rates.

Depuration occurred quickly. Total flupyradifurone residues in eggs, fat, liver, and muscle from the 54N ~~43N~~ ~~49N~~ dose level hens declined from 1.722, 1.230, 3.480, and 2.410 mg/kg, respectively, to <LOQ at 14 days after cessation of dose administration (=day 42 of the study).

DFA residues represented 65% to 74% of the total flupyradifurone residues in the excreta samples, suggesting significant exposure of the laying hens to DFA residues following the administration of BYI 02960 for 29 days.

Flupyradifurone was administered orally to dairy cows for 29 consecutive days at average *actual* dose rates of 4.8 mg/kg feed (1.6N ~~1.8N~~ ~~2N~~ dose), 23 mg/kg feed (8N ~~9N~~ ~~8N~~), 50 mg/kg feed (17N ~~19N~~ ~~18N~~), and 135 mg/kg feed (44N ~~52N~~ ~~49N~~).

After the final dose, the animals were sacrificed and the key edible tissues were analyzed for the relevant residues of BYI 02960.

The combined residues of BYI 02960 + DFA in bovine tissues at sacrifice in the 1.6N ~~1.8N~~ ~~2N~~ dosing group were 0.063 mg/kg in muscle, 0.041 mg/kg in fat, 0.18 mg/kg in kidney, and 0.17 mg/kg in liver, expressed in parent compound equivalents. Prior to sacrifice, residues in milk were measured at various intervals in the high-dose group, and on day 28 in the three lower dose groups. In the 1.6N ~~1.8N~~ ~~2N~~ dose group, the residues (BYI 02960 + DFA) amounted to 0.043 mg/kg.

Residue levels reached a plateau in milk. Highest residue were determined at day 17 in the 44N ~~52N~~ ~~49N~~ milk samples, remaining at similar levels for the remainder of the study.

Depuration occurred quickly. Total BYI 02960 residues in milk, fat, liver, kidney, and muscle from the 44N ~~52N 49N~~ dose level cows declined from 0.81, 1.40, 1.59, 5.39, and 1.91 mg/kg, respectively, to <LOQ at 6-7 days after cessation of dose administration (=day 35-36 of the study).

Livestock will be exposed to DFA and flupyradifurone through feed as these are the major residues in plants. Based on the data from the feeding studies in which only parent flupyradifurone was dosed, transfer factors were proposed to estimate consumer exposure and to calculate MRLs for the sum of DFA and flupyradifurone. The feeding studies were designed to allow "material balancing" in order to evaluate levels and calculate transfer factors for both the total residue (parent BYI 02960 and DFA) and DFA, despite feeding parent compound only. Since this not an accepted approach, it was concluded in the expert meeting thatfeeding studies with DFA are required. In the meantime, the available study will be used for provisional MRL setting.

Residue intakes by livestock animals and humans

Intake by livestock

A dietary burden calculation was performed for ~~the sum of~~ flupyradifurone and DFA separately, resulting in a maximum dietary burden of 0.06, 0.20 and 0.19 ~~1.52, 2.61 and 2.57~~ ~~1.32, 2.73 and 2.50~~ mg BYI 02960/kg feed and 1.27, 2.40 and 2.36 mg DFA/kg feed for poultry, cattle and pigs, respectively.

Intake by humans

Chronic and acute exposure for the consumer was estimated using the proposed MRLs, the ADI of 0.064 ~~0.08~~ ~~0.12~~ mg/kg bw/d, the ARfD of 0.15 ~~0.35~~ mg/kg bw and EFSAs PRIMo model rev.2. The IEDI ~~TMDI~~ uses maximally 15.1% ~~47.3~~ ~~75.6~~% of the ADI for the WHO Cluster diet B. All other European (national) diets use less of the ADI.

The NESTI uses maximally 82.3 ~~69.2~~% ~~of the ARfD UK infants for oranges (import tolerance) and 69.2%~~ of the ARfD for German children for lettuce after refinement with the HR-P. All other commodities use less of the ARfD in other consumer diets.

2.4.3 Residues relevant to worker safety

Exposure of the worker is discussed under 2.3.4.

2.4.4 Proposed MRLs and compliance with existing MRLs

Flupyradifurone is a new active substance, and is not on the market yet. No MRLs have been set.

2.5 Environmental fate and behaviour

2.5.1 Definition of the residues relevant to the environment

Detailed guidance to define the environmental residue is available in SANCO/10329/2002 rev 2. final (Oct 2002) and SANCO/3268/2001 rev 4 final (Oct 2002). All metabolites accounted for >10% in aerobic soil treated with BYI 02960.

The components of the environmental residue are therefore as follows:

Residue definition for risk assessment:

Soil:	Flupyradifurone (BYI 02960), difluoroacetic acid (DFA), 6-chloronicotinic acid (6-CNA)
Surface Water:	BYI 02960, DFA, 6-CNA, BYI 02960-succinamide, BYI 02960-azabicyclosuccinmaide
Sediment:	BYI 02960, DFA, 6-CNA
Groundwater:	BYI 02960, DFA, 6-CNA
Air:	BYI 02960

Residue definition for monitoring:

Soil:	BYI 02960
Surface Water:	BYI 02960
Groundwater:	BYI 02960
Air:	BYI 02960

2.5.2 Fate and behaviour in soil

Route of degradation

Aerobic soil degradation

The route of Flupyradifurone (BYI 02960) degradation in soil was studied using different radiolabel positions, [pyrindinyl-methyl-^{14}C = PYM], [pyridine-2,6-^{14}C = PYR], [furanone-4-^{14}C = FUR] and [ethyl-1-^{14}C = ETH] BYI 02960. The data gathered in the aerobic soil metabolism studies demonstrated that BYI 02960 is degraded in soil.

When using the PYM label in four different European aerobic soils no major metabolites were detected. All formed metabolites were regarded as transient, which was confirmed by the high mineralization rate to $^{14}CO_2$, i.e. up to 58.6% of AR from [PYM-^{14}C] BYI 02960. The portions of not extractable residues (NER) were comparatively low throughout the study (max 16.8% of AR) in case of [PYM-^{14}C] BYI 02960. As minor transformation products BYI 02960-chloro (max. 1.8%) and BYI 02960-des-difluoroethyl (max. 0.4%) were identified (for structures see Figure 2.5.2-01).

In studies with the FUR label (four European and two US soils) similar results were obtained with the formation of NER (maximum 34.1% of AR) and extensive mineralization to $^{14}CO_2$ (up to 38.9% of AR). With the exception of $^{14}CO_2$ no major metabolites were formed in any of the soils. Degradation, amount of NER as well as of $^{14}CO_2$ formed in sterilized was significantly less than in non-sterile soils, indicating a biological component to the degradation/mineralization and formation of non-extractable residues from BYI 02960. Additionally, soil fractionation showed that even with extraction using strong base, BYI 02960 related residues remain bound to the solid (humin) fraction indicating very strong and irreversible binding to soil.

When using [ETH-^{14}C] BYI 02960 in three aerobic soils one major metabolite, identified as difluoroacetic acid (DFA; max. 33.9% of AR), and one very minor metabolite was detected and quantified. Again, significant amounts of $^{14}CO_2$ (up to 42.3% AR) were measured, indicating that mineralization of the test item and/or its metabolites occurred. The maximum amount of NER was relatively low at 17.9% of AR.

The biotransformation of [PYR-^{14}C] BYI 02960 was studied in one aerobic EU and two US soils. The mineralization to $^{14}CO_2$ was significant (max. 57.4, 20.2 and 36.1% of AR) with the formation of minor metabolites in two soils. However, in one US soil, one major metabolite, which was identified as 6-chloronicotinic acid (6-CNA), was formed at maximum of 17.1%. NER formation was in the range of max. 11.3 to 25.5% of AR in the three soils.

Considering the results from laboratory soil metabolism studies the major routes of degradation of BYI 02960, under aerobic conditions, are:

- cleavage of the difluoroethyl group producing difluoroacetic acid (DFA),
- cleavage of the molecule at the pyridinylmethylene bridge with subsequent oxidation to 6-CNA
- mineralization to CO_2 and formation of non-extractable residues.

Degradation under anaerobic conditions and due to photolysis on the soil are not relevant for BYI 02960.

The biotransformation of BYI 02960 was studied in several EU and US soils under standardized aerobic and anaerobic laboratory conditions, as well as in a terrestrial field dissipation study performed on six different sites in Europe. BYI 02960 was found to be moderately degradable in aerobic soil under laboratory as well as under field conditions. The clear bi-phasic degradation kinetics indicates that the compound is less available for biotransformation with time, probably due to a time-dependent sorption behavior in soil. The BYI 02960 residues remain stable under anaerobic conditions.

Figure 2.5.2-01 Proposed degradation pathway of BYI02960 in soil

Note: The degradates observed and the maximum values are those for all label positions and soils

Anaerobic soil degradation

Three studies investigating the degradation of [PYR-^{14}C], [FUR-^{14}C] and [ETH-^{14}C] BYI 02960 in soils under aerobic, then flooded anaerobic conditions showed that it can be expected that the amounts of BYI 02960 and its major aerobic soil metabolites DFA and 6-CNA remain stable under flooded field conditions. Degradation would be expected to continue according to the proposed overall pathway of degradation of BYI 02960 (see Figure 2.5.2-01) whenever the conditions in soil turn aerobic again.

Soil photolysis

Phototransformation of [PYM-^{14}C] and [FUR-^{14}C] BYI 02960 was studied on a loam soil. From the results it is concluded that direct phototransformation of BYI 02960 is not regarded as a relevant degradation process in the environment. The soil photolytic DT_{50} of BYI 02960 was 99.6 and 109.3 days.

Rate of degradation

Laboratory studies

The following Table 2.5.2-01 summarises the findings in the aerobic laboratory studies. The kinetics data for the metabolite 6-CNA indicate that it is very rapidly degraded in soil with a mean DT_{50} of < 1 week. The metabolite DFA indicated a slightly longer DT_{50}, i.e. it was calculated to be in the range of approx. 2 months.

Field studies

Soil dissipation of BYI 02960 under European field conditions was investigated after application of BYI 02960 SL 200 on bare soil plots at sites in Monheim, Burscheid and Hanscheider Hof (all Germany), Great Chishill (United Kingdom), Albaro (Italy), and Vilobi d'Onyar (Spain). An application was also made in Chilly (Northern France), however the trial was aborted due to heavy rain shortly after application. The sites are located in the ecoregions Northern and Southern Europe.

In general, BYI 02960 residues remained in the upper 0-20 cm soil layer and only very small amounts (<LOQ) were translocated to a maximum depth of 30 cm. At one site (Vilobi d'Onyar, Spain), BYI 02960 residues just above the LOQ were found at day 13 up in the 20-30 cm soil layer. BYI 02960 dissipated from soil at all test sites with DT_{50} values ranging from 8.3 to 251 days.

The metabolite BYI 02960-DFA appeared in the upper soil layer 0-20 cm in amounts of up to 17.4 g/ha soil. However, the metabolite declined to values of max. 7.9 g/ha soil towards the end of the study (in Burscheid, Germany). An overview of the results for parent compound is given in Table 2.5.2-02.

The field data is not different from the laboratory data in that it does not result in different DT_{50}-values on average. The average DT_{50}-value for the non-normalized field studies is 38.4 days (geometric mean) and 40.0 days (median) comaperd to the laboratory DT_{50}-values of 72.2 and 59.7 days. A normalization might be conducted, since these values are not required for modelling this is not conducted.

Table 2.5.2-02 Results for BYI 02960 in field dissipation studies

Location: Trial No.	Soil type (USDA)	Kinetic model	DT50 [d]	DT90 [d]
Monheim (Germany): 09-2702-01	Sandy loam (0-100 cm)	DFOP	41.0	749

		Gemetric mean	**38.4**	**482.3**
		Median	**40.0**	**531.5**

PECsoil estimations

Calculations were based on a simple first tier approach (Excel sheet) assuming even distribution of the compound in upper 0-5 cm soil layer. A standard soil density of 1.5 g/cm^3 was assumed. Crop interception data which correspond to the intended growth stages were taken from the FOCUS groundwater guidance paper (FOCUS 2010).

Crop interception will reduce the amount of a compound reaching the soil and therefore this has been taken into account depending on the growth stage at application. The interception rates follow the recommendations of the FOCUS groundwater guidance paper (FOCUS 2010) provided in Table 2.5.2-03. As hop and lettuce have not been defined in the FOCUS groundwater guidance paper, vines and cabbage were chosen as surrogate crops. As there is currently no guidance on calculation of PEC_{soil} for greenhouse crops no specific calculation was performed and it is assumed that the glasshouse use is covered by the outdoor use on lettuce.

Flupyradifurone (BYI 02960)

The predicted environmental concentrations in soil (PEC_{soil}) of BYI 02960 were estimated using a simple first tier approach (Excel sheet). Detailed application data used for simulation of PEC_{soil} are compiled in Table 2.5.2-03. PEC soil were not calculated for the glasshouse uses of the product.

PEC_{soil} calculations were based on the DT_{50} of 0.2 days for the fast and 462 days for the slowly degrading compartments (DFOP, worst case of field dissipation studies, k_1=34.66 and k_2=0.0015 and g =0.27).

Table 2.5.2-03 Application pattern used for PEC_{soil} calculations of BYI 02960

Individual Crop	FOCUS Crop Used for Interception	Application				Amount Reaching the Soil per Season application [g a.s. /ha]
		Rate per Season [g a.s. /ha]	Interval [days]	Plant Interception [%]	BBCH Stage

Lettuce 1 (F), GAP – identical with simulation [1)]	Cabbage	1 x 125	-	25	12-49	1 x 94
Lettuce 2 (F), GAP – identical with simulation [2)]	Cabbage	1 x 125	-	70	41-49	1 x 37.5

[1)] Max 1 application per 24 months (biennial)
[2)] Max 1 application per 12 months (annual)
F = field use

To account for potential accumulation of BYI 02960 in soil (worst-case non-normalised DFOP DT_{90} > 365 days), long-term soil concentrations were calculated.

The PEC_{soil} and the time weighted average values (TWA_{soil}) of BYI 02960 are summarised in Table 2.5.2-04 for hops and in for lettuce Table 2.5.2-05.

Table 2.5.2-04 PEC_{soil} (actual) and TWA of BYI 02960 in hops in the upper 5 cm, DFOP decay

[1)] Max 1 application per 24 months (biennial)
[2)] Max 1 application per 12 months (annual)

Accumulation in soil

The potential accumulation of BYI 02960 in soil was calculated considering the following approaches:

- Maximum soil residue in first year: maximum soil residue calculated for one season.
- Long-term plateau concentration C_{min}: maximum of the lower saw tooth curve, which can be considered as background concentration after multiple year use.
- Long-term maximum concentration C_{max}: maximum of the upper saw tooth curve after multiple year use.
- Background C_{min} + maximum of one year in 5 cm depth: to the long-term background concentration C_{min} in a certain depth (e.g. 5, 10 or 20 cm), the maximum residue of one year (distributed in 5 cm) will be added, to take into account a conservative shallow distribution just after an annual application.

Table 2.5.2-06 Long-term soil concentrations of BYI 02960 following multi-year use

	Residues distributed over … [cm]	Seasonal $PEC_{s, max}$, max. soil residue in 1st year [mg/kg]	Long-term plateau / background conc. C_{min} [mg/kg]	Long-term maximum conc. C_{max} [mg/kg]	Background C_{min} + max. of 1 year in 5 cm [mg/kg]
Hops 1 x 150 g/ha	**5**	0.080	0.080	**0.160**	-
	10	0.040	0.040	0.080	0.120
	20	0.020	0.020	0.040	0.100
Lettuce 1 [1)] 1 x 125 g/ha	5	0.125	0.046	0.171	-
	10	0.063	0.023	0.085	0.148
	20	0.031	0.011	0.043	**0.136**
Lettuce 2 [2)] 1 x 125 g/ha	5	0.050	0.050	0.100	-
	10	0.025	0.025	0.050	0.075
	20	0.013	0.013	0.025	**0.063**

[1)] Max 1 application per 24 months (biennial)
[2)] Max 1 application per 12 months (annual)
In bold: Generally, for long-term assessments the substance distribution in soil for annual crops with tillage should be assumed over a depth of 20 cm (lettuce) and for perennial crops without tillage over a depth of 5 – 10 cm (e.g. hops).

Metabolites

Predicted environmental concentrations in soil were calculated for the major soil metabolites DFA and 6-CNA. These metabolites are not automatically "relevant" with regard to their environmental, biological, eco-toxicological or toxicological properties.

PEC_{soil} for the metabolites were calculated using the approach, scenarios and application rates described for the calculations for the parent compound in study IIIA, 9.4/01. Compound specific parameters are summarised in Table 2.5.2-07.

Table 2.5.2-07 Input parameters for PEC_{soil} for metabolites of BYI 02960

Compound	Max. DT_{50} [days]	Max. occurrence in soil [%]	Molar mass [g/mol]	Molar mass correction factor
Difluoroacetic acid	73.6	33.9	96.03	0.333
6-Chloronicotinic acid	36.6	17.1	157.56	0.546

The maximum PEC_{soil} values of metabolites of BYI 02960 are summarised in Table B.8.3-06.

Table 2.5.2-08 Hops and Lettuce: PEC_{soil} (max) of BYI 02960 metabolites

Crop	DFA $PEC_{soil, max}$ [mg/kg]	6-CNA $PEC_{soil, max}$ [mg/kg]
Hops 1 x 150 g/ha of parent	0.009	0.007
Lettuce 1, 1 x 125 g/ha of parent [1)]	0.014	0.012
Lettuce 2, 1 x 125 g/ha of parent [2)]	0.006	0.005

[1)] Max 1 application per 24 months (biennial)
[2)] Max 1 application per 12 months (annual)

Sorption parameters

Batch adsorption studies BYI 02960

Batch adsorption studies were performed for BYI 02960 and two major soil metabolites. The equilibrium sorption BYI 02960 was studied in two batch equilibrium studies in the laboratory at 20°C with six different soils and one time dependent sorption experiment. The data of the batch experiments were evaluated to derive Freudlich isotherms. The resulting arithmetic mean value for 1/n, Kf (ads) and Koc was 0.866, 2.263 (L/kg) and 91.8 (L/kg; Table 2.5.2-09). The desorption Kf (des) and the normalized K_{OC}(des) values were significantly higher (i.e. approx. 2 times) than those obtained for the adsorption phase, indicating that the test item once adsorbed to soil is not readily desorbed. BYI 02960 can be classified as intermediate mobile for adsorption and low mobile for desorption.

Table 2.5.2-09 Adsorption measurements for BYI 02960

Soil	Soil Type (USDA)	pH ($CaCl_2$) [-]	K_f [mL g^{-1}]	1/n [-]	$K_{f,oc}$ [mL g^{-1}]
Laacherhof AXXa	Sandy loam	6.2	2.077	0.8445	98.9

* $K_{oc,EQ}$ restults of the TDS included in the average caluclation

Time dependent sorption study BYI 02960

Time dependent sorption (TDS) of BYI 02960 was studied in four soils a maximum period of 120 days under aerobic conditions in the dark at ca. 20°C and 55% WHCmax. At the beginning of the study the distribution coefficient values RTDS were 1.46, 1.91, 3.35 and 4.66 mL/g for soils AX, HF, HN and DD, respectively. Based on results from the ageing time of 120 days, the RTDS values increased by a factor of 4.4, 2.9, 3.2 and 2.6 (mean of all four soils = 3.3).

A more detailed evaluation showed that the before-mentioned experimental data can be well described by a kinetic-sorption model, with excellent fits and reliable parameter estimates. Such time-dependent sorption data received for BYI 02960 constitute the prerequisite to adequately address the obvious TDS process in higher tier regulatory modelling, e.g. related to a potential groundwater contamination. For BYI 02960 a fitted mean K_{oc} of 80.2 L/kg (K_{om} of 46.5 L/kg) and the Freundlich

exponent 1/n of 0.8605 can be used in higher tier simulation runs (arithmetic mean of the 1/n of the four soils used for the batch sorption and identiacal as the soils used for TDS).

The RMS intended to use both the batch adsorption and time dependent sorption (TDS) K_{oc} and $K_{oc,eq}$ to obtain a arithmetic mean K_{oc}. The RMS did this on basis of the EFSA opinion on the science behind the guidance for scenario selection and scenario parameterisation for predicting environmental concentrations of plant protection products in soil (ESFA Journal 2012;10(2)2562). It is advised to use in each tier, all available relevant scientific information. The RMS was aware that in the draft guidance on how aged sorption studies for pesticides should be conducted, analysed and used in regulatory assessments (Beulke S. and Van Beimum W. 2012, DEFRA projects PS2235 and PS2244) a different opinion is presented, and not to combine the TDS and batch adsorption/desorption data. This UK guidance on TDS is not yet adopted in Europe and also the opinion is not adopted. After a discussion with the applicant and external experts, the RMS decided to not include the TDS $K_{oc,EQ}$ data in the first tier data set for the K_{oc}. The arithmetic mean K_{oc} value is 98.4 L/kg, this is the average of the six batch adsorption values.

Batch adsorption studies for metabolites

The equilibrium sorption of 6-chloronicotinic acid (6-CNA) was studied in experiments using five soils and an aquatic pond sediment. The arithmetic mean 1/n value for soil was 0.9495, adsorption Koc values in soils ranged from 70 to 258, averaging 88.0 (L/kg). Similar Kf and Kdes values for all soils and the pond sediment indicated a reversible equilibration between adsorption and first desorption phases. 6-CNA can be classified as medium to high mobile for adsorption and desorption.

The equilibrium sorption of difluoroacetic acid (DFA) was studied in experiments using five soils. The arithmetic mean 1/n value for soil was 0.8348, adsorption Koc values ranged from 1.7 to 9.5, averaging 6.8 (L/kg). The Koc(des) values were 12.7 to 57.1 times higher than the Koc(ads) values, indicating a strong binding of the test item to the soil. BYI 02960-DFA can be classified as very mobile for adsorption and low mobile for desorption.

The results of the batch adsorption analyses performed for the metabolites are reported below (see Table 2.5.2-10 and Table 2.5.2-11).

Table 2.5.2-10 Adsorption measurements for 6-chloronicotinic acid

PECgw estimations

The predicted environmental concentrations in groundwater (PEC_{gw}) for BYI 02960 and its metabolites were calculated using the simulation model FOCUS PEARL (version 4.4.4) and FOCUS PELMO (4.4.3). Detailed application data used for simulation of PEC_{gw} are compiled in Table 2.5.2-12 to Table 2.5.2-16. Simulations were conducted for annual applications as well as applications performed every second year.

Although there is no currently agreed model for simulating groundwater concentrations following the use in greenhouses as a conservative approach the simulation was performed as an outdoor application considering two applications in accordance with the GAP.

Table 2.5.2-12 Comparison of simulated and actual use pattern

Individual Crop	FOCUS Crop Used for Interception	Application				Amount Reaching the Soil per Season application [g a.s. /ha]

Further input parameters for PEC_{gw} modelling of BYI 02960 are summarised in Table 2.5.2-17 for BYI 02960 and in Table 2.5.2-18 for the metabolites. Parameters used for degradation pathway in PEARL and PELMO are depicted in Table 2.5.2-19.

For Tier 1, a geometric mean of half-lives derived from SFO and from the slow compartment of the DFOP model was used to obtain a conservative model input.

For Tier 2a, (DFOP) according to FOCUS (2009), DFOP degradation kinetics was considered in leaching modelling based on the procedure described in FOCUS (2006).

To obtain common DFOP parameters over all soils the following procedure was applied: Firstly, all degradation curves following SFO kinetics on Tier-1 were converted to an equivalent DFOP model where the Tier-1 SFO-DT_{50} was assigned equally (g=0.5) to the slow and fast degrading compartment. For those soils where the slow compartment of DFOP was already used for modelling at Tier-1, the corresponding shorter DT_{50} of the fast compartment and g (fraction of total amount applied to the compartment) of the DFOP fit were additionally considered. Finally, the DFOP parameters were calculated as mean over all soils.

For leaching modelling the application rate was doubled and assigned to both compartments according to g of 0.43. Then, two separate leaching simulations were performed: one for the fast compartment using DT_{50fast} of 33 days and one using DT_{50slow} of 95 days. Both PEC_{gw} values were summed up and divided by two to get the final result.

Tier 2b (TDS): Time dependent sorption (TDS) data of BYI 02960 on four soils were derived via curve fitting (study IIA, 7.4.1/05). These parameters constitute the prerequisite to adequately address TDS processes in regulatory exposure modelling (Beulke, S. and van Beinum, W. 2012)[1]. Experimental soil data were re-calculated to fit the TDS model, resulting in a geometric mean DT_{50_eq} of 57.9 days, an arithmetic mean K_{OM_eq} of 47.5 L/kg, an arithmetic mean f_ne of 0.5821, a geometric mean $k_{_des}$ of 0.0309 and an arithmetic mean Freundlich exponent of 0.8605 from the optimized parameters of the four data sets. The PECgw calculations given in this part are based on the average/geometric mean parameters obtained from the individual soil. At the end of this paragraph a comparison with the PECgw from each separate soil data set is given as was proposed in the draft guidance on TDS (Beulke, S. and van Beinum, W. 2012).

Table 2.5.2-17 Substance specific and model related input parameters for PEC_{gw} calculation of BYI 02960

Thiva	*0.026*	*0.020*	*0.008*	*0.006*

In italics: values pass the trigger of 0.1µg/L

When considering TDS behaviour the predicted concentrations of BYI 02960 in groundwater are below the trigger of 0.1 µg/L in the scenario Porto, Sevilla and Thiva (models PEARL and PELMO) when applied every year and in all scenarios (both PEARL and PELMO), when applied every second year.

A safe use has been demonstrated as the trigger of 0.1 µg/L is met at tier 1, considering application every year, for the scenario Sevilla (PELMO). For the higher tier calculations applying DFOP the trigger was met in Sevilla and Thiva for annual applications. When considering higher tier calculations with TDS the trigger was also met in several scenarios for annual uses and all scenarios for use every second year.

Flupyradifurone in lettuce

The PEC_{gw} values for the metabolites for the different EU scenarios are presented for glasshouse uses in the following tables. The glasshouse uses (multiple applications) are presented solely since these will result in the highest PECgw.

Table 2.5.2-23 Tier 1 PEC_{gw} of BYI 02960 – Use in Lettuce 2, multiple applications (glasshouse use)

Scenario	BYI 02960 (glasshouse use / every year)			
	Lettuce 2, 1st cropping, every year, 2 x 125 g/ha		Lettuce 2, 2nd cropping, every year, 2 x 125 g/ha	
	PEARL PEC_{gw} [µg/L]	PELMO PEC_{gw} [µg/L]	PEARL PEC_{gw} [µg/L]	PELMO PEC_{gw} [µg/L]

Thiva	0.606	0.438	-	-

In italics: values pass the trigger of 0.1µg/L

For the greenhouse use in lettuce, using the Tier 2a approach (DFOP) the trigger is met for the scenario Sevilla for annual application even considering the conservative use of the outdoor model.

Table 2.5.2-25 Tier-2b (TDS) PEC_{gw} of BYI 02960 – Use in Lettuce 2, multiple applications (glasshouse use)

Scenario	BYI 02960 (glasshouse use / every year / TDS)			
	Lettuce 2, 1st cropping, every year, 2 x 125 g/ha		Lettuce 2, 2nd cropping, every year, 2 x 125 g/ha	
	PEARL PEC_{gw} [µg/L]	PELMO PEC_{gw} [µg/L]	PEARL PEC_{gw} [µg/L]	PELMO PEC_{gw} [µg/L]
Châteaudun	0.245	0.155	0.334	0.214
Hamburg	0.677	0.520	0.905	0.784
Jokioinen	0.185	0.145	-	-
Kremsmuenster	0.475	0.404	0.568	0.502
Porto	0.259	0.355	0.508	0.627
Sevilla	*0.006*	*0.001*	*0.007*	*0.001*
Thiva	0.181	0.119	-	-

In italics: values pass the trigger of 0.1µg/L

For the greenhouse use in lettuce, using the Tier 2b approach (TDS) the trigger is met for the scenario Sevilla for annual applications, even considering the conservative use of the outdoor model. For all the uses considered safe use can be demonstrated in at least 1 scenario even considering tier 1 calculations. When higher tier (Tier 2) simulations are considered the calculated PEC_{gw} is less than the trigger in several scenarios.

Flupyradifurone metabolites in hops

PEC_{gw} for the metabolites were calculated using the approach, scenarios and application described for the calculations for the parent compound in studies IIIA 9.6.1. Compound specific input data for the metabolites are summarised together with the data of the parent compound in Table 2.5.2-18.

Findings: The 80th percentile concentrations for BYI 02960 metabolites for the different EU scenarios are presented in Table 2.5.2-26 for Tier 1.

Table 2.5.2-26 Tier 1 PEC_{gw} of BYI 02960 metabolites (after application of 150 g BYI 02960/ha) in hops

Scenario	Difluoroacetic acid (DFA) PEC_{gw} [µg/L]				6-Chloronicotinic acid (6-CNA) PEC_{gw} [µg/L]

In italics: values pass the trigger of 0.1µg/L
In bold: values pass the trigger of 0.75 µg/L

PEC_{gw} values for the metabolite DFA are above 0.1 µg/L for all scenarios (both PEARL and PELMO), and for applications taking place every year or every 2nd year, respectively. PEC_{gw} values for the metabolite 6-CNA are below 0.1 µg/L for all scenarios (both PEARL and PELMO) for applications taking place every year or every 2nd year, respectively. There are no concerns for groundwater for this metabolite.

Additionally, for difluoroacetic acid (DFA), higher tier have been performed, the results are summarized below Table 2.5.2-27 and Table 2.5.2-28.

Table 2.5.2-27 Tier 2a (DFOP): PEC_{gw} of difluoroacetic acid (DFA) in hops (1 x 150 g/ha of parent)

Sevilla	1.185	0.917	1.589	1.280
Thiva	2.727	2.416	-	-

In italics: values pass the trigger of 0.1 µg/L
In bold: values pass the trigger of 0.75 µg/L

Considering the use in the glasshouses the PEC_{gw} values for the metabolite DFA are above 0.1 µg/L for all scenarios (both PEARL and PELMO), and for applications taking place every year, at Tier 1 and Tier 2. PEC_{gw} values for the metabolite 6-CNA are below 0.1 µg/L for all scenarios (both PEARL and PELMO) at tier 1, and for applications taking place every year, respectively. There are no concerns for groundwater for this metabolite.

The groundwater concentration of the metabolite 6-CNA did not exceed the trigger in any scenario. The PEC in groundwater for the metabolite DFA may exceed the 0.1 µg/L and also the 0.75 µg/L trigger, the concentration was < 10 µg/L in all scenarios The relevance of the metabolite has been assessed in accordance with Sanco/221/2000–rev.10 (2003): “Guidance Document on the Assessment of the Relevance of Metabolites in Groundwater”, and the metabolite was not relevant in terms of efficacy (see IIA, 8.14.1), genotoxicity and toxicity (see IIA, 5.8/01 - 05) and has also been considered in the dietary risk assessment (see IIA, 6.9). Please note: DFA was considered in the dietary risk assessment since it is a constituent of the plant residue definition.

2.5.3 Fate and behaviour in water

Hydrolysis

BYI 02960 proved to be stable under sterile hydrolytically conditions at all pHs.

Photo degradation in water

Sterile buffer

[^{14}C] BYI 02960 photolytically degraded in sterile buffer (pH 7) with a half-life of 13.8 experimental hours. Based on this finding, BYI 02960 should degrade within a few days in the aqueous environment if exposed to sunlight. The major degradates (>10% of applied radioactivity) were identified as [^{14}C] BYI 02960-succinamide and [^{14}C] BYI 02960-azabicyclosuccinamide.

Natural waters

BYI 02960 photolytically degraded in sterile natural water with a half-life of 14.0 experimental hours. The major degradates (>10% of applied radioactivity) were identified as BYI 02960-succinamide and BYI 02960-azabicyclosuccinamide. A minor degradation product was identified as BYI 02960-deschlorohydroxy-succinamide. In the dark controls BYI 02960 was stable. Based on the experimental half-life of 14.0 hours, the half-life of BYI 02960 under environmental conditions in Tokyo, Japan was calculated to be 3.8 days. The phototransformation study in natural water is regarded more relevant for the aqueous environment as the pure and sterile buffer study.

Biodegradability

Ready biodegradability

A respective study was not performed. The parent compound BYI 02960 is considered to be “Not Readily Biodegradable (as shown by the studies IIA, 7.8.2/01; IIA, 7.8.3/01 and IIA, 7.8.3/02).

Water/sediment studies

Five different water/sediment studies were submitted in the dossier. An anerobic water sediment study, two aerobic water sediment studies (one with one label and one with two labels). The fourth water sediment study was with the metabolite DFA. The final study was an outdoor microcosm study.

Anaerobic conditions

BYI 02960 dissipated from aqueous phase to sediment with a half-life of 7.2 and 9.6 days for Lawrence and Pikeville test system, respectively. With respect to the entire test system, BYI 02960 is regarded stable under anaerobic condition, no major metabolite were formed.

Aerobic conditions

[PYR] BYI 02960 is microbially degraded in aerobic water/sediment systems. The DT_{50} values for BYI 02960 in the entire water/sediment systems were 193.1 and 246.9 days for Hönniger Weiher and Angler Weiher, respectively. The only major transformation products were to carbon dioxide and formation of NER .

[FUR] and [ETH] BYI 02960 is translocated from the water phase into the sediment where it is slowly degraded and mineralized. Major transformation products were mineralization to carbon dioxide, formation of NER and one metabolite, DFA, (max. 6.9% of AR). The DT_{50} values for BYI 02960 in the entire water/sediment systems were 208.2 [FUR], 202.4 [ETH] and 246.1 [FUR], 285.0 [ETH] days for Hönniger Weiher and Angler Weiher, respectively.

The dissipation of DFA from the supernatant water phase was characterized by translocation into the sediment and by slowly degradation. With the exception of mineralization to carbon dioxide and formation of NER no major metabolite was found. The DT_{50} values for DFA in the entire water/sediment systems were 106.5 (persistence), 109.0 (modelling) and 967.1 (persistence) 567.2 (modelling) days for Hönniger Weiher and Angler Weiher, respectively.

Microcosm study

BYI 02960 dissipated from the supernatant water phase with a mean DT_{50} of 81 days due to translocation into the sediment and by degradation. The overall degradation (mean of 95.1 days) was faster under the prevailing outdoor conditions in comparison to the laboratory water sediment studies. Considering that BYI 02960 is rapidly degraded by photolysis there may be an enhanced degradation effect of sunlight under the outdoor test conditions.

The degradation route of BYI 02960 in aqueous environments is shown in Figure B.8.4.4-01.

Figure 2.5.3-01 Proposed route of degradation of BYI 02960 in water/sediment systems (BYI 02960 rapidly partitioned into the sediment phase, DFA is mainly present in water phase)

Note: The degradates to be observed as well as the given maximum values are highly dependent on radiolabel and kind of study considered; Ph = photo-transformation

PECsw estimations

Calculation of PEC values for the active substance and metabolites according to FOCUS

$FOCUS_{sw}$ is a four step tiered approach:

Step 1: In this, the most conservative step, all inputs are considered as a single loading to the water body and a worst-case PEC_{sw} and PEC_{sed} is calculated.

Step 2: A refinement is made whereby individual loadings into the water body from different entry routes are considered. Scenarios are also considered for Northern and Southern Europe separately but no specific crop scenarios are defined.

Step 3: An exposure assessment using realistic worst-case scenarios is made. The scenarios are representative of agricultural conditions in Europe and consider weather, soil, crop and different water-bodies. Simulations use the models PRZM, MACRO and TOXSWA.

Step 4: PEC values are refined by considering mitigation measures or specific scenario descriptions on a case-by-case basis.

The PEC values in water and sediment were calculated at Step 1, 2, 3 and 4 for the parent substance. Only global maximum values were calculated, which can be used as conservative estimates of the actual and time-weighted average values assuming no degradation. Study design, compound characteristics and application were the same as for the PEC_{sw} calculations as for the PEC_{sed}.

Note: There are currently no European guidelines for the assessment of exposure of surface water from the use in glasshouses, therefore it was assumed that the use in glasshouses on lettuce is covered by the outdoor field use even considering the different use pattern.

Flupyradifurone (BYI 02960)

Predicted environmental concentrations in surface water and sediment (PEC_{sw} and PEC_{sed}) of BYI 02960 have been calculated for the use in hop and lettuce in Europe employing the tiered FOCUS Surface Water approach. All relevant entry routes of a compound into surface water (principally a combination of spray drift and runoff/erosion or drain flow) were considered in these calculations.

Details of the parameters used in the calculations are summarised in Table 2.5.3-05.

As there is currently no established model for the assessment of exposure of surface water following application in greenhouses the use is assumed to be covered by the field application even considering the higher use rate in greenhouses as the route of entry into surface water would be expected to be much lower following the use in greenhouses.

Table 2.5.3-05 Comparison of actual and calculated use pattern (for FOCUS step 1 & 2)

Individual Crop	FOCUS Crop Used for Interception	Application				Amount Reaching the Soil per Season application [g a.i. /ha]
		Rate per Season [g a.i. /ha]	Interval [days]	Plant Interception [%]	Growth Stage

Step 4

The maximum PEC_{sw} and PEC_{sed} values for relevant FOCUS Step 4 scenarios with mitigation options are given in the following tables.

Table 2.5.3-11 Maximum PEC_{sw} and PEC_{sed} values of BYI 02960 at Step 4 including drift reduction (without buffer) – Hops (1 x 150 g/ha)

Step 4		BYI 02960: Hops, 1 x 150 g/ha							
Buffer Width & Type	FOCUS Scenario	PECsw [µg/L] Drift Reduction				PECsed [µg/kg] Drift Reduction			
		25%	50%	75%	90%	25%	50%	75%	90%
0m (drift)	R1 (pond, 1st)	0.296	0.197	0.099	0.039	0.607	0.415	0.218	0.094
	R1 (stream, 1st)	4.149	2.766	1.383	0.553	0.273	0.184	0.093	0.072

Table 2.5.3-12 Maximum PEC_{sw} and PEC_{sed} values of BYI 02960 at Step 4 including buffer zones and drift reduction – Hops (1 x 150 g/ha)

Step 4		BYI 02960: Hops, 1 x 150 g/ha							
Buffer Width & Type	FOCUS Scenario	PEC_{sw} [µg/L] Drift Reduction				PEC_{sed} [µg/kg] Drift Reduction			
		0%	50%	75%	90%	0%	50%	75%	90%
5m (drift)	R1 (pond, 1st)	0.445	0.223	0.111	0.045	0.891	0.465	0.244	0.105
	R1 (stream, 1st)	4.515	2.258	1.129	0.452	0.297	0.151	0.076	0.071
10m (drift & run-off)	R1 (pond, 1st)	0.253	0.126	0.063	0.025	0.522	0.273	0.142	0.061
	R1 (stream, 1st)	2.354	1.177	0.589	0.235*	0.157	0.080	0.04	0.031
15m (drift & run-off)	R1 (pond, 1st)	0.141	0.071	0.035	0.014*	0.302	0.158	0.083	0.036
	R1 (stream, 1st)	1.554	0.777	0.388	0.155*	0.104	0.053	0.032	0.03
20m (drift & run-off)	R1 (pond, 1st)	0.078	0.039	0.02*	0.008*	0.174	0.091	0.048	0.021
	R1 (stream, 1st)	0.708	0.354	0.177*	0.071*	0.048	0.025	0.017	0.016

* reduction of the overall drift percentage is >95%, compared to STEP3, in case drift leads to PECsw max.

The mitigation from 10 m onwards includes spray drift and concurrent run-off buffer. However, as can be seen from the linear decrease of PEC_{sw} values with increasing drift reduction, the PEC_{sw} is always drift dominated and the run-off buffer does not drive the PEC_{sw}.

The step 4 PEC_{sw} for the pond scenario with 5 m buffer and 0% drift reduction is higher compared to the step 3 value. This is due to the default buffer width of 6 m already included in step 3 calculations resulting in a lower drift percentage of 2.63% compared to 2.97% in step 4.

Table 2.5.3-12 Maximum PEC_{sw} and PEC_{sed} values of BYI 02960 at Step 4 including drift reduction (without buffer) – Lettuce 1 (1 x 125 g/ha, field use)

BYI 02960 metabolites

For BYI 02960, the metabolites difluoracetic acid (DFA), 6-chloronicotinic acid (6-CNA) and BYI 02960-succinamide and BYI 02960-azabicyclosuccinamide were assessed.

Materials and Methods: PECsw for the metabolites were calculated using the approach, scenarios and application rates described for the calculations for the parent compound in study IIA, 9.7/01. Input parameters for the metabolites are described in Table 2.5.3-17.

Table 2.5.3-17 Substance specific and model related input parameters for PECsw calculation

Parameter	Unit	DFA	6-CNA	BYI 02960-succinamide	BYI 02960-azabicyclo-succinamide

2.5.4 Fate and behaviour in air

Based on the estimation method according to structure-activity relationship (SAR) methods developed by Roger Atkinson and co-workers the chemical lifetime of the BYI 02960 in the air was assessed by the program AOPWIN^{TM}, version 1.92a (U.S. EPA, 2008). The half-life time ($t_{1/2}$) was estimated within a range of 4.4 hours (short-term scenario) to 13.1 hours (long-term scenario), depending on the mean concentration of hydroxyl radicals present in the troposphere.

In addition, BYI 02960 is susceptible to reactions with ozone, however, that attack and its resulting chemical half-life is considered to be slower by a factor of 2 to 10.

As a consequence of the short half-life in air, no long-range transport of BYI 02960 in the atmosphere is likely to occur nor an accumulation of BYI 02960 in the environmental compartment air. From the low vapor pressure of the substance it is concluded that very low, if any, quantities of BYI 02960 are expected to enter the atmosphere from volatilization.

PECair estimations

As a consequence of the short half-life in air, no long-range transport of BYI 02960 in the atmosphere is likely to occur nor an accumulation of BYI 02960 in the environmental compartment air. From the low vapor pressure of the substance it is concluded that very low, if any, quantities of BYI 02960 are expected to enter the atmosphere from volatilization of soil residues.

2.6 Effects on non-target species

2.6.1 Effects on terrestrial vertebrates

2.6.1.1 Birds

The risk assessment procedure follows the EFSA Guidance Document on Risk Assessment for Birds & Mammals (2009).

Routes of exposure

The formulation is to be sprayed on hops in the field and on lettuce in glasshouses and in the field.

The following routes are considered:

- direct dietary exposure: scenarios for hop and leafy vegetables – field uses only
- direct exposure via drinking water: field and glasshouse uses
- indirect exposure by consumption of earthworms and fish containing residues of BYI 02960 field and glasshouse uses

Acute, short-term and (sub-)chronic dietary toxicity data

Toxicity studies with BYI 02960 (flupyradifurone) were performed with Bobwhite quail (*Colinus virginianus*), canary (*Serinus canaria*) and mallard duck (*Anas platyrhynchos*). The acute oral toxicity of the formulated product was determined in studies on Bobwhite quail (*Colinus virginianus*) and in Chicken (*Gallus gallus domesticus*). There is no indication that the formulation is more toxic than expected based on the active substance content.

Endpoint selection was done according to the recommendations of the Guidance Document on Risk Assessment for Birds & Mammals, EFSA 2009[3]:

Acute risk assessment: where acute tests for more than one species are available the geometric mean may be used for the refined assessment, except when the endpoint for the most sensitive species is more than a factor 10 below the geometric mean of all the tested species. For BYI 02960, in a worst-case approach the lowest LD50 of 232 mg/kg bw is used for Tier 1 acute risk assessment.

Short-term risk assessment; According to the risk assessment scheme a short-term risk assessment is not required. However, the endpoint from short-term dietary studies, e.g. 5-day dietary study in birds (OECD 205) should be used in an acute risk assessment when indicating a higher toxicity via the dietary exposure route (lower LDD50). In the case of BYI 02960 there is no indication that 5-day exposure via dietary route would provoke higher toxicity than one application via gavage in acute study and therefore the short-term toxicity is not considered in the acute risk assessment.

Reproductive risk assessment: The acute oral LD50 value used in the acute avian assessment should

[3] EFSA (2009): Guidance Document on Risk Assessment for Birds & Mammals on request from EFSA. The EFSA Journal (2009), 7(12):1438.

be divided by 10 for comparison with the lowest NOAED from the reproduction study (studies) ignoring purely parental effects (e.g. changes in parental body weight and food consumption). The lower of the values should be used in the tier 1 risk assessment.
For BYI 02960 the endpoint from the reproduction study (14 mg/kg bw/d) is lower than the 1/10th of the LD50 of 232 mg/kg bw that has been proposed for use in the Tier 1 acute risk assessment. Therefore, the endpoint of 14 mg/kg bw will be used in a Tier 1 reproductive risk assessment for birds.

An overview of accepted toxicity data for a.s. and formulation is given in Table 2.6.1.1-01. Endpoints selected for first tier risk assessment are marked **bold.**

Table 2.6.1.1-01 Overview of accepted toxicity data for BYI 02960 and BYI 02960 SL 200

Study	Substance	Species	Route	Criterion	Value [mg/kg fd]	Value [mg a.s./kg bw·d]

Risk assessment

Exposure via feed

Calculation of Toxicity Exposure Ratio (TER)

According to the EFSA Guidance Document on Risk Assessment for Birds & Mammals (2009), the calculation of acute and long-term Toxicity to Exposure Ratio (TER) is defined as follows:

Acute risk: TERa = LD50 [mg as/kg bw] / DDDac

Long-term risk: TERlt = [lowest of NOEL and LD50/10] [mg as/kg bw] / DDDmean

Calculation of Daily Dietary Dose (DDD)

Acute exposure DDDac:

The daily dietary dose for a single application per crop is given by the following equation:

DDDACac = application rate [kg/ha] × shortcut value (SV90)

Long-term exposure DDDmean:

For a single application the daily dietary dose is given by the following equation:

DDDmean = application rate [kg/ha] × shortcut value (SVm) × fTWA

Where

DDD Daily dietary dose

fTWA Time weighted average factor ftwa based on a default time window of 21 days and a DT50 of 10 days leading to a value of 0.53

90 90th percentile values for acute exposure

m mean values for reproductive/long-term exposure

Standard exposure scenario for Tier 1 risk assessment

The main potential exposure route for birds is expected to be consumption of contaminated feed. This is only relevant for field uses.

The Tier 1 risk assessment is based on generic focal species associated with specific crop scenarios. Default ("shortcut"-) values for the exposure estimate will be used as provided in Appendix A of the EFSA Guidance Document on Risk Assessment for Birds & Mammals (2009) representing a worst case assessment.

In the Tier 1 risk assessment it is assumed that

- animals satisfy their entire food demand in the treated area (PT = 1),
- over an acute time frame (hours) the animals feed on items containing maximum residues (90th percentile), whereas they would ingest food containing mean residues over a long-term period (days to weeks),
- long-term predicted environmental concentrations to be compared with chronic endpoints can be calculated as the time-weighted average concentration. Default assumptions are a time window of 21 days and a DT50 of 10 days leading to a time weighted average factor (= ftwa) of 0.53. This factor is equally valid for feed items consisting of vegetation and for arthropods.

Avian generic focal species for Tier 1 risk assessment

In the field, the product is intended to be used in hops at BBCH 31-75 and in lettuce at BBCH 12-49. According to the EFSA Guidance Document on Risk Assessment for Birds & Mammals (2009) the following generic focal species are addressed in Tier 1 risk assessment.

Table 2.6.1.1-02: Relevant generic avian focal species for Tier 1 risk assessment

Crop	Growth stage (BBCH)	Generic focal species	Representative species	Shortcut value	
				For long-term RA based on RUD_m	For acute RA based on RUD_{90}
Hops	≥ 20	Small insectivorous bird "finch"	Chaffinch	**10.6**	**25.3**
	20-39	Small granivorous bird "finch"	Goldfinch	**5.7**	**12.3**
	≥ 40	Small granivorous bird "finch"	Goldfinch	3.4	7.4
Lettuce (Leafy vegetables)	10-19	Medium herbivorous/granivorous bird "pigeon"	Wood pigeon	**22.7**[1]	**55.5**[1]
	10-49	Small granivorous bird "finch"	Serin	**12.6**	**27.4**
	10-49	Small omnivorous bird “lark”	Woodlark	**10.9**	**24.0**
	10-19	Small insectivorous bird “wagtail”	Yellow wagtail	**11.3**	**26.8**
	≥ 20	Small insectivorous bird “wagtail”	Yellow wagtail	9.7	25.2

Bold values were used for Tier 1 risk assessment. Where the same focal species is representative for different BBCH stages, only the worst-case SV values were chosen for the Tier 1 risk assessment.

[1] The long-term and acute SV-values for this scenario reported in the EFSA GD are 37.0 and 90.6, respectively. However, these were mistakenly based on a FIR/bw of 1.29 (calculated for a passerine species) instead of 0.79 (for non-passerine species, which is correct for the pigeon). The corrected values are in line with those reported for the “pigeon” in early stages of legume forage, maize and oilseed rape.

Tier 1 acute toxicity exposure ratio for birds

Table 2.6.1.1-03: Tier 1 acute DDD and TER calculation for birds

Crop (BBCH)	Generic focal species	LD50 [mg/kg bw]	DDD			DDD	TERA	Trigger
			Appl. rate [kg/ha]	SV90	MAF90			
BYI 02960								
Hops (≥ 20)	Small insectivorous bird "finch"	232	0.150	25.3	1	3.80	61	10
Hops (20-39)	Small granivorous bird "finch"			12.3		1.85	126	
Lettuce (10-19)	Medium herbiv./ granivorous bird	232	0.125	55.5	1	6.94	33	10

	"pigeon"							
Lettuce (10-49)	Small granivorous bird "finch"			27.4		3.43	68	
Lettuce (10-49)	Small omnivorous bird "lark"			24.0		3.0	77	
Lettuce (10-19)	Small insectivorous bird " wagtail"			26.8		3.35	69	

The TER values for both crops are above the trigger of 10 for acute exposure. Hence, no unacceptable acute risk to birds from the use of the product according to the intended use pattern is to be expected.

Tier 1 long-term toxicity exposure ratio for birds

Table 2.6.1.1-04: Tier 1 long-term DDD and TER calculation for birds

Crop (BBCH)	Generic focal species	NO(A)EL [mg/kg bw/d]	DDD				DDD	TERLT	Trigger
			Appl. rate [kg/ha]	SVm	MAFm	fTWA			
BYI 02960									
Hops (≥ 20)	Small insectivorous bird "finch"	14	0.150	10.6	1.0	0.53	0.84	16.6	5
Hops (20-39)	Small granivorous bird "finch"			5.7			0.45	31.9	
Lettuce (10-19)	Medium herbiv./graniv. bird "pigeon"	14	0.125	22.7	1.0	0.53	1.50	9.3	5
Lettuce (10-49)	Small granivorous bird "finch"			12.6			0.83	16.8	
Lettuce (10-49)	Small omnivorous bird "lark"			10.9			0.72	19.4	
Lettuce (10-19)	Small insectivorous bird " wagtail"			11.3			0.75	18.7	

The TER values for both crops are above the trigger of 5 for long-term exposure. It is noted that targeted residue decline data are available in the section on wild mammal risk assessment, which indicate that the TER values for (partly) herbivorous birds are even underestimated.

Hence, no unacceptable risk to birds from the use of the product according to the intended use pattern in lettuce and hops is to be expected.

Metabolites

In the residue section of the DAR, metabolites DFA and DFEAF are considered relevant:

Plants

Residue definition for monitoring:

Results from supervised residue trials show that flupyradifurone and difluoroacitic acid (DFA) are, by far, the most prominent components of the residues in target plants and rotational crops. The residues of metabolite difluoroethyl-amino-furanone (DFEAF) were below the LOQ of 0.01 mg/kg in virtually all samples. Considering these results as well as those from the metabolism studies, the proposed residue definition for monitoring for target plants and rotational crops is:

The sum of parent compound and DFA, expressed in flupyradifurone equivalents.

Residue definition risk assessment:

For flupyradifurone residues in target plants (primary crops) and rotational crops (succeeding crops), the proposed residue definition for data collection and risk assessment is:

The sum of parent compound flupyradifurone and its metabolites DFA and difluoroethyl-amino-furanone (DFEAF), expressed in flupyradifurone equivalents. A conversion factor is not required to cover the difference between the residue definition for monitoring and risk assessment as bith DFA and flupyradifurone are part of the residue definition for monitoring and as DFEAF is found in levels below <0.01 mg/kg in supervised residue trials and in rotational crops.

In the human toxicology risk assessment, the following is concluded:

Toxicologically relevant compounds (animals and plants)	Parent compound, DFA
Toxicologically relevant compounds (environment)	Parent compound, DFA

Based on the above, metabolite DFA is considered to be relevant for the terrestrial vertebrate risk assessment.

No avian toxicity study is conducted with DFA but mammalian toxicity data suggest no higher toxicity of the metabolite than from the parent.

Furthermore, the residue data from trials in lettuce and cereals (as surrogate for ground vegetation in hops) demonstrate little difference in the decline DT50 whether or not DFA is included in the residue concentrations. The trials indicate mostly faster dissipation on foliage than the default DT50 of 10 days.

The first tier risk assessment is therefore based on initial maximum concentrations of the a.s. and the

generic DT50 of 10d and this is considered to cover metabolite DFA.

Exposure via drinking water

An assessment of the risk potentially posed by consumption of contaminated drinking water is required according to the EFSA Guidance Document for Birds and Mammals (2009).
Two scenarios were identified as relevant for assessing the risk of pesticides via drinking water to birds and mammals:

- Leaf scenario, only relevant for birds possibly drinking water from puddles in leaf whorls after application of a pesticide to a crop and subsequent rainfall or irrigation. This scenario is only relevant for acute exposure and only for certain crop types. When the product is applied in hops, the formation of pools in leaf axils where an acute exposure possibly might occur can be excluded. However, for lettuce, the risk of birds drinking from puddles in leaf whorls cannot be excluded. Hence, a corresponding risk assessment has been performed below.
- Puddle scenario. Birds and mammals taking water from puddles formed on the soil surface of a field when a (heavy) rainfall event follows the application of a pesticide to a crop or bare soil. This scenario is relevant for all types of applications that may cause contamination of soil and only for long-term exposure.

<u>Risk assessment for the leaf scenario (field use in lettuce):</u>
The exposure of birds to drinking water from pools in leaf whorls as outlined above cannot be excluded from the use of the product in lettuce.
The respective calculations for birds have to be performed only for acute exposure. Generic focal species is a small granivorous bird (body weight 15.3 g) with a DWR (daily drinking water rate) of 0.46 L/kg bw/d. It should be mentioned that DWR, unlike FIR in the case of food intake exposure assessment, is already related to body weight.
According to EFSA Guidance Document for Birds and Mammals (2009), the PECpool calculates as follows:

PECpool = Cspray / 5 [mg/L]

Cspray = 0.025 kg a.s./hL = 25 g a.s./hL = 0.25 g a.s./L = 250 mg a.s./L

The PECpool (= PECdw) is 250 / 5 = 50 mg a.s./L for BYI 02960. The calculation of DDD (here: daily drinking water uptake) and TER are as follows:

DDD = DWR * PECdw

TERA = LD50 [mg as/kg bw/d] / DDD [mg as/kg bw/d]

Table 2.6.1.1-05: Tier 1 acute DDD and TER calculation for exposure via drinking water from pools in leaf axils or on leaves

Compound	DWR [L/kg bw/d]	PECdw [mg/L]	DDD [mg/kg bw/d]	LD50 [mg/kg bw]	TER_A	Trigger
BYI 02960	0.46	50	23	232	10.1	10

The TER_{AC} value for drinking water exposure exceeds the a-priori acceptability trigger of 10 in a worst case risk assessment (highest concentration in spray water volume, lowest LD50). Hence, no unacceptable risk is to be expected from the use of the product according to the intended use pattern.

Risk assessment for the puddle scenario (field use in hop and lettuce):

An “escape clause” recommended in the EFSA Guidance Document for Birds and Mammals (2009) allows for screening the need for a quantitative risk assessment by a comparison between the application rate and the toxicity of the respective substance. This escape clause specifies that “*due to the characteristics of the exposure scenario in connection with the standard assumptions for water uptake by animals …, no specific calculations of exposure and TER are necessary when the ratio of effective application rate (= application rate x MAF) (in g/ha) to relevant endpoint (in mg/kg bw/d) does not exceed 50 in the case of less sorptive substances (Koc < 500 L/kg) or 3000 in the case of more sorptive substances (Koc ≥ 500 L/kg).*” [4].

Table 2.6.1.1-06: Evaluation of potential concern for exposure of birds drinking water from puddles (escape clause)

Compound	Koc [mL/g]	Application rate * MAF [g a.i./ha]	LD50 or NO(A)EL [mg a.i./ kg bw/d]	Ratio (Application rate * MAF) / NO(A)EL	“Escape clause” No concern if ratio	Conclusion
BYI 02960	98.4 1)	150 2) x 1	232	0.64	≤ 50	No concern
			14	10.7	≤ 50	No concern

1) Arithmetic mean of ten K_{OC} values (see B.5)

2) Worst-case application rate in hops

This evaluation confirms that the risk for birds from drinking from puddles that may contain residues from the use of product is acceptable.

[4] EFSA (2009): Guidance Document on Risk Assessment for Birds & Mammals on request from EFSA, p. 66

Indirect exposure via contaminated earthworms or fish

Substances with a high bioaccumulation potential could theoretically bear a risk of secondary poisoning for birds if feeding on contaminated prey like fish or earthworms. For organic chemicals, a log P_{OW} > 3 is used to trigger an in-depth evaluation of the potential for bioaccumulation.

Table 2.6.1.1-07: Log Pow values of BYI 02960 and its metabolites

Substance	Maximum Log Pow	Reference
BYI 02960	1.2	Vol.3 B.2.1.13
BYI 02960-succinamide	0.6 at pH 5	Vol.3 B.2 Table B.2.1-2 IIA 7.13b
BYI 02960-azabicyclosuccinamide NA-salt	-1.3 at pH 5	Vol.3 B.2 Table B.2.1-2 IIA 7.13b
DFA	- 3.1 at pH5	Vol.3 B.2 Table B.2.1-2 IIA 7.13b
6-CNA	1.52 at pH 1.98	Vol.3 B.2 Table B.2.1-2 IIA 7.13b

As neither the active ingredient nor any of its metabolites has a log Pow above 3, the potential of bioaccumulation is considered to be low. Hence, there is no need to evaluate potential effects of secondary poisoning of birds.

2.6.1.2 Mammals

The risk assessment procedure follows the EFSA Guidance Document on Risk Assessment for Birds & Mammals (2009).

Routes of exposure

The formulation is to be sprayed on hops in the field and on lettuce in glasshouses and in the field.

The following routes are considered:

- direct dietary exposure: scenarios for hop and leafy vegetables – field uses only
- direct exposure via drinking water: field and glasshouse uses
- indirect exposure by consumption of earthworms and fish containing residues of BYI 02960 field and glasshouse uses

Acute and chronic toxicity data

The summary of the toxicity profile of the active substance BYI 02960 to mammals is provided in Table 2.6.1.2-01. Details of the studies concerned are provided in B.6 of this DAR.

Table 2.6.1.2-01 Toxicity of BYI 02960 to mammals

Test species	Test design	Ecotoxicological endpoint	Reference
Acute risk assessment endpoint:			
Rat	acute oral, toxic class method	$LD_{50, cut-off}$ [1] 2000 mg a.i./kg bw (4/6 dead at 2000, 0/6 at 300)	[redacted] (2009) B.6.2.1 Study 1
Rat	acute oral neurotoxicity study	LD_{50} > 800 mg a.i./kg bw (2/24 dead at 800, 0/24 at 200 and below)	Garcin (2009) B.6.7.1 Study 1
Combined LD_{50} calculation (TOXCALC, probit): 1607 mg/kg bw			
Reproductive risk assessment endpoint:			
Rat reproduction	Dietary exposure over 2 generations	$NOAEL_{maternal}$ 6.~~47.8~~ [1] (100 ppm) mg a.i./kg bw/d $NOAEL_{repro}$ 34 ~~39.2~~ [2] (500 ppm) mg a.i./kg bw/d $NOAEL_{offspring}$ 6.~~47.8~~ [1] (100 ppm) mg a.i./kg bw/d	[redacted] (2011) B.6.6.1 Study 2
Rat developmental toxicity	Gavage over GD 6-20 (gestation days)	$NOAEL_{maternal}$ 50~~15~~ mg a.i./kg bw/d $NOAEL_{offspring}$ 50 mg a.i./kg bw/d	[redacted] (2010)
Rabbit developmental toxicity	Gavage over GD 6-28 (gestation days)	$NOAEL_{maternal}$ 15 mg a.i./kg bw/d $NO(A)EL_{offspring}$ 40 mg a.i./kg bw/d	[redacted] (2012)
Reproductive risk assessment endpoint proposal of notifier		**Tier 1:** 6.~~47.8~~ **mg/kg bw/d**	
		Tier 2 (refined): 34 ~~39.2~~ **mg/kg bw/d**	

1) Mean achieved dose of P & F1 females at 100 ppm (Table 5.6-14 of KIIA 5.6.1/02, [redacted], 2011) In B.6, the NOAEL is based on the lowest intake by either males or females during a particular study phase, in this case intake by males F1-gen during premating, see Table 6.6.1-8 of Vol3 B.6.

2) Mean achieved dose of P & F1 females at 500 ppm (Table 5.6-14 of KIIA 5.6.1/02, [redacted], 2011) In B.6, the NOAEL is based on the lowest intake by either males or females during a particular study phase, in this case intake by males F1-gen during premating, see Table 6.6.1-8 of Vol.3 B.6.

There are no indications that the formulated product enhances the toxicity of the a.s., see the Table below.

2.6.1.2-02 Mammalian toxicity data of the formulated product BYI 02960 SL 200

Test species	Test design	Ecotoxicological endpoint	Reference
Rat	acute, oral	LD50 >2000 mg/kg bw [1]	[redacted] (2010) B.6.12.1 Study 1

1) 0 out of 6 animals died. According to OECD Guideline 423, the LD50 cut-off of BYI 02960 SL 200 is >5000 mg/kg body weight (equivalent to Category 5 (unclassified) of the GHS).

The proposed **acute endpoint of 1607 mg/kg bw** (derived by combining the mortality data from the two acute studies with oral exposure with the a.s.) is accepted.

As long-term endpoint, the notifier proposes a maternal and offspring NOAEL of 100 ppm (7.8 mg/kg bw/d) for tier 1 risk assessment. ~~As a worst-case approach is acceptable but RMS notes that in the mammalian toxicology section of the DAR the endpoints are set at a higher dose level. Also for the developmental studies the endpoints in B.6 of the DAR are higher. See Table B.9.3.3-2.~~

~~Table B.9.3.3-2 Endpoints from 2-generation study in rats and developmental studies in according to B.6.6.1~~

~~Study type~~	~~Reproductive endpoint determined in B.6 :~~	~~Dose (ppm):~~	~~Dose (mg/kg bw/d):~~	~~Based on intake during study phase:~~
~~Rat reproduction~~	~~Relevant parental NOAEL~~	~~500 ppm~~	~~32 mg/kg bw/day~~	~~premating, P-gen, males~~
~~Rat reproduction~~	~~Relevant reproductive NOAEL~~	~~500 ppm~~	~~34 mg/kg bw/day~~	~~gestation, P-gen, females~~
~~Rat reproduction~~	~~Relevant offspring NOAEL~~	~~500 ppm~~	~~34 mg/kg bw/day~~	~~gestation, P-gen, females~~
~~Rat developmental~~	~~Relevant maternal NOAEL~~		~~50 mg/kg bw/day~~	
~~Rat developmental~~	~~Relevant offspring NOAEL~~		~~50 mg/kg bw/day~~	
~~Rabbit developmental~~	~~Relevant reproductive NOAEL~~		~~40 mg/kg bw/day~~	
~~Rabbit developmental~~	~~Relevant offspring NOAEL~~		~~40 mg/kg bw/day~~	

~~Based on the above, the endpoint proposed by the notifier for the first tier is considered to be very conservative.~~ For a tier 2 assessment, the notifier reconsidered this endpoint. Their statement is presented below, with minor modifications by RMS, regarding references to Tables and dossier sections. RMS also incorporated the changes made following Pesticide Peer Review meeting 122 of mammalian toxicology.

According to the refinement options provided in the EFSA GD (Section 4.4, Module 4: Reproductive

risk assessment for mammals, step 9), the Tier 1 endpoint can be refined after re-examination of the reproductive studies for endpoints relevant for reproductive performance. Effects on other endpoints can be disregarded. In this context the EFSA GD specifies a number of potentially relevant endpoints to be evaluated, including body weight, behavior and reproductive performance of adults, and observations on offspring (number, weight, development). A corresponding evaluation for BYI 02960 is presented in the table below, based on the toxicological studies summarized in more detail B.6 of this dossier. If such refinement of the Tier 1 endpoint is considered, the EFSA GD recommends that additional mammalian toxicity studies should also be examined in order to check whether they contain lower NOAELs for relevant endpoints.

Approach taken in this evaluation:

In order to ensure a high level of protection, all repeated dose oral toxicity studies conducted with BYI 02960 in rodents (rat, mouse), rabbits or dogs were evaluated for potentially relevant endpoints. This evaluation included also neurotoxicity studies, in order to account for non-lethal behavioral effects that could become relevant under field conditions.

Since the protection goal of the reproductive risk assessment is the sustainability of potentially exposed wild mammal populations, these studies were evaluated with regard to population level relevant endpoints, i.e. survival, growth, development, behavior and reproductive performance. Other endpoints (e.g. organ weights, physiology, blood chemistry etc.) were not included in the evaluation. Furthermore, neither very high doses (more than 3-fold above the proposed refined endpoint), nor chronic studies of extreme exposure duration (≥ 1 year) were included in the tables.

Since effects on females are typically more relevant for small mammal populations than effects on males, the results of this evaluation are presented in Table 2.6.1.2-04 in the order of increasing achieved doses for females over all evaluated studies. In order to facilitate the comparison of effects at the different dose levels of each study, the letter code in the first column indicates the study ID (letters A-N, as presented in the following overview table), with the respective dosing group indicated by numbers 1-3 (low, mid and high dose level).

Table 2.6.1.2-04 Repeated oral dosing toxicity studies evaluated for selection of the Tier 2 wild mammal reproductive risk assessment endpoint in Table 2.6.1.2-05

Study ID	Study type	Report reference

N	DOG 90d	B.6.3.4 Study 3, KIIA 5.3.3/01

Results of this evaluation:

Most prominent in the evaluation of all these repeated oral dosing studies with BYI 02960 (see Table 2.6.1.2-04) were observations of moderate body weight effects. Severity of effects was seen to increase with dose and exposure time.

Within reasonable timeframes of environmental exposures (weeks to months), effects of ecological relevance on wild mammal population did not occur at dose levels of at least 30-50 mg/kg bw/d.

In contrast, pronounced reproductive effects of clear ecological relevance did occur at dose levels significantly exceeding 100 mg/kg bw/d (e.g., 14.8% litter size reduction and reduced body weight of > 10% at 120-150 mg/kg bw/d (1800 ppm) in the rat 2-generation study), and only after prolonged exposure in a second generation (F1 females or F2 offspring).

Moderate effects of bodyweight can usually be considered less relevant in wild mammal risk assessments. Moreover, the results of the 90-d rat study with BYI 02960 showed that bodyweight effects approaching 10% (e.g., 8.9% in males and 9.5% in females at 500 ppm) were reversible after cessation of treatment (recovery phase). Potential exposure of wild mammals to BYI 02960 is transient and short-lived (single application, DT50 on foliage ≤ 5 days). Therefore an effect magnitude of ≤ 10% on bodyweight can be considered ecologically acceptable. Body weight effects exceeding this magnitude were not observed at dose levels below 140 mg/kg bw/d (P females: 15.9%), even after prolonged exposure.

Reproductive effects like reduction of litter size were only moderately pronounced and were only observed after long-term exposure in F1 parents and F2 litter (note: not observed in the 1-generation rat reproduction study nor in the first generation of the 2-generation study), indicating reduced risk for reproductive effects under environmentally relevant conditions (low application rate, single application, DT50 on foliage < 5 days).

Overall, this evaluation suggests that a dose level of up to 39.2 mg as/kg bw/d (achieved dose of females at 500 ppm in the 2-gen rat reproduction study) can be proposed as relevant and sufficiently conservative risk assessment endpoint for wild mammal populations:

- no ecologically relevant effects in the parental generation or the F1 litter
- only slight reductions of bodyweight (< 10%) in F1 parents and F2 litter
- body weight reduction by BYI 02960 of ca. 10% was reversible after cessation of dosing.

Severe effects only occurred at dose levels which were 3-4 times higher than 39.2 mg/kg bw/d.

Therefore the refined wild mammal reproductive risk assessment endpoint proposed in this dossier is 39.2 mg as/kg bw/d, the achieved dose of females at 500 ppm in the 2-gen rat reproduction study.

Table 2.6.1.2-05 Potentially relevant wild mammal reproductive risk assessment effects of BYI 02960 in repeated oral dosing studies

F: females; M: males; ↑: increase (higher than control); ↓: reduction (lower than control);
P: parental generation M+F; F1: offspring produced by P M+F, F2: offspring produced by F1 M+F
#: number; bw: body weight; FC: food consumption
n.e.: not evaluated (specific study type without reproductive endpoints); empty fields: no effect observed. Blue shading indicates the NOAELs as determined by RMS in B.6 of the original DAR. Green shading indicates the NOAELs as determined in the updated version of B.6 of December 2014 following Pesticide Peer Review meeting 122.

*NOAEL set by RMS in original DAR but not accepted in peer review.

~~RMS agrees with the notifier that the ecologically relevant endpoint for wild mammals is the mid-dose of the two-generation study in rats (500 ppm). Based on the mammalian toxicology assessment (see table B.9.3.3-2) this corresponds to **34 mg/kg bw/d,** based on intake by females of the P-generation during the gestation period. This is considered to be the relevant endpoint for the ecotoxicological risk assessment.~~

Expert consultation during Pesticide Peer Review meeting 124, ecotoxicology, December 2014:

The 1-year dog study concluded an endpoint of 7.8 mg/kg bw (mammalian toxicity section, original DAR) and it was questioned whether this should be taken into account.

Furthermore, the endpoint from the 2-generation rat study has changed to ‘parental‘ and ‘offspring‘ NOAEL of 6.4 mg/kg bw per day (100 ppm) and ‘reproductive’ NOAEL of 32 mg/kg bw per day (500 ppm). The ‘parental‘ NOAEL of 6.4 mg/kg bw per day is based on significant decrease in body weight (<10% observed in the mid-dose of the F_1 females) and a non-significant decrease in body weight gain found in the parental animals (21% in females) and the F_1 animals (16% in females). The ‘offspring‘ NOAEL of 6.4 mg/kg bw per day is based on reduced body weight/body weight gain in the F_2 pups. These were agreed by the meeting of experts for mammalian toxicology (PESTICIDES PEER REVIEW MEETING 122).

Discussion:

The 1y-dog study was considered as not relevant for ecotox for reproductive risk assessment. Some observed effects (degeneration of skeleton muscle and other muscle degeneration) from this study might be considered as relevant but not for the reproduction. It was noted that in general such type of study is not considered robust by tox experts (few test individuals).

The discussion was focussed on the 2-generation rat study. Three endpoints are available from this study, NOAEL of 500 ppm for reproduction and 100 ppm for offspring and parental toxicity. A dose response relationship was noted for the pup body weight decrease. At 500 ppm the decrease was statistically significant but < 10%. It was questioned if this should be considered as biologically

relevant. At 1800 ppm (the next higher dose) the decrease was >10%. Some experts considered that the statistical significance in this case should not be disregarded considering also the dose response relationship and preferred the lowest NOAEL of 100 ppm.

Overall, the majority of the experts considered that a NOAEL of 100 ppm should be used for risk assessment (**6.4 mg a.s./kg bw/d**).

Risk assessment

Exposure via feed

The first tier risk assessment calculation of is performed in the same way as for birds. The risk assessment procedure follows the EFSA Guidance Document on Risk Assessment for Birds & Mammals (2009).

Mammalian generic focal species for Tier 1 risk assessment

In the field, the product is intended to be used in hop at an application rate of 1 x 0.150 kg a.i./ha, BBCH 31-75, and in lettuce at an application rate of 1 x 0.125 kg a.i./ha, BBCH 12-49. According to the EFSA Guidance Document on Risk Assessment for Birds & Mammals (2009) the following generic focal species have to be addressed in the risk assessment.

Table 2.6.1.2-06 Relevant generic mammalian focal species for Tier 1 risk assessment

Crop	Growth stage (BBCH)	Generic focal species	Representative species	Shortcut value	
				For long-term RA based on RUD mean	For acute RA based on RUD 90th perc.
Hops	≥20	Small insectivorous mammal “shrew”	Common shrew	**1.9**	**5.4**
	≥ 40	Small herbivorous mammal "vole"	Common vole	**21.7**	**40.9**
	20 - 39	Small omnivorous mammal “mouse”	Wood mouse	**3.9**	**8.6**
	≥ 40	Small omnivorous mammal “mouse”	Wood mouse	2.3	5.2
Lettuce (Leafy vegetables)	10-19	Small omnivorous mammal “shrew”	Common shrew	**4.2**	**7.6**
	≥20	Small insectivorous mammal “shrew”	Common shrew	1.9	5.4
	40-49	Small herbivorous mammal "vole"	Common vole	**72.3**	**136.4**
	≥ 50	Small herbivorous mammal	Common vole	21.7	40.9

		"vole"			
	All season	Large herbivorous mammal "lagomorph"	Rabbit	**14.3**	**35.1**
	10-49	Small omnivorous mammal "mouse"	Wood mouse	**7.8**	**17.2**
	≥ 50	Small omnivorous mammal "mouse"	Wood mouse	2.3	5.2

Bold values were used for Tier 1 risk assessment. Where the same focal species is representative for different BBCH stages, only the worst-case SV values were chosen for risk assessment.

The acute and long-term risk are calculated in the tables below.

Table 2.6.1.2-07 Tier 1 acute DDD and TER calculation for mammals

Crop	Generic focal species	LD_{50} [mg/kg bw]	DDD			DDD	TER_A	Trigger
			Appl. rate [kg/ha]	SV_{90}	MAF_{90}			
BYI 02960								
Hops (≥20)	Small insectivorous mammal "shrew"	1607	0.150	5.4	1	0.81	1984	10
Hops (≥ 40)	Small herbivorous mammal "vole"			40.9		6.14	262	
Hops (20 – 39)	Small omnivorous mammal "mouse"			8.6		1.29	1246	
Lettuce (≥20)	Small insectivorous mammal "shrew"	1607	0.125	5.4	1	0.68	2381	10
Lettuce (40-49)	Small herbivorous mammal "vole"			136.4		17.05	94	
Lettuce (All season)	Large herbivorous mammal "lagomorph"			35.1		4.39	366	
Lettuce (10-49)	Small omnivorous mammal "mouse"			17.2		2.15	747	

All TER values for both crops are well above the trigger of 10 for acute exposure. Hence, no unacceptable risk is to be expected from the use of the product according to the intended use pattern.

Table 2.6.1.2-08 Tier 1 long-term DDD and TER_{LT} calculation for mammals

Crop	Generic focal species	NOAEL [mg/kg bw/d]	DDD				DDD	TER_{LT}	Trigger
			Appl. rate [kg/ha]	SV_m	MAF_m	f_{TWA}

Bold values do not meet the trigger

All TER values for both crops are above the trigger of 5 for long-term exposure, except for the generic focal species the "vole". ~~Hence, no unacceptable risk is to be expected from the use of the product according to the intended use pattern.~~

Based on the first tier endpoint of 7 mg/kg bw/d proposed originally by the notifier, a risk would be identified for small herbivorous mammals. Therefore, the notifier has proposed two further refinements:

I. measured residue data that allow refinement of the time-weighted average residue concentrations (21-d fTWA) of BYI 02960 on foliage as potential diet of small herbivorous mammals
II. a more realistic evaluation of the focal species exposure scenario (relevance of hop yards and lettuce fields for voles), based on general knowledge from literature and field study results.

<u>I) Refined DT50 of BYI 02960 on foliage</u>

According to the recommendations of the EFSA GD (2009), the Tier 1 risk assessment has been conducted with a “generic” DT50 of 10 days of BYI 02960 on all food items. However, measured residue decline data (Vol. 3, B.7.6.2 study 1 to 4 KIIIA1 6.3.1/01-04 for lettuce, and Vol. 3, B.9.3.2 Study IIIA 10.3.3/02 for cereals) are available that allow the calculation of compound-specific DT50 values for BYI 02960.

From the available residue decline data, it is proposed to select substrates and application types that can be considered representative for foliage as food of small herbivorous mammals in lettuce fields (i.e., spray application residue trial results) and in hop yards (spray application residue trials in young cereals as surrogate for wild undergrowth).

With these data, specific DT50 values for BYI 02960 were calculated by Scherr & Ellerich (2013),; lettuce: KIIIA 10.3.3/03; and Sur & Ellerich (2012), cereals: KIIIA 10.3.3/04) according to best practice in environmental modelling. The residue decline data were analysed with the software package KinGUI, which is a standard tool used for kinetic evaluations. In the first place, fits using the single first order (SFO) model were performed. Their quality was assessed visually and also based on statistical significance of the individual parameters. In case of clear biphasic behaviour in the respective residue data, a DFOP fit (double-first order in parallel) was also performed. Also here, visual acceptability and statistical significance were evaluated.

Residue decline data were analysed both for flupyradifurone only and for total residues of flupyradifurone including also metabolites DFA and DFEAF.

In all trials residues were determined after the second treatment, but in four trials residues were also determined after the first application and DT50 values were estimated for each decline interval.

As a result of KinGUI evaluation, 13 trials in lettuce provided SFO – DT50 values and 5 trials provided a DFOP-DT50. One trial provided an SFO-DT50 value after the first application and an DFOP-DT50 after the second application.

In young cereals, 3 trials provided SFO – DT50 values and 1 trial provided a DFOP-DT50.

Half-live (DT50) values from SFO and DFOP cannot be simply mathematically averaged in order to generate an overall DT50 to be used in time-weighted average (TWA) calculations. Since the (single) DT50 from SFO fits cannot simply be averaged with the (double) DT50 from DFOP fits, calculations of the 21-d fTWA were conducted for each of the trials, and the 17 resulting 21-d fTWA values were combined afterwards. With this approach the full set of available data can be included in the refined exposure assessment.

The TWA values themselves were thus calculated in a second step as follows. First, numerical evaluation of predicted residues in time (with timestep of 0.1 days) was performed, employing the respective kinetic type and the relevant degradation parameter(s) - DT50 value(s) and g-factor (for DFOP). These predicted residues are then used for the 21-d fTWA evaluation per data set and averaged afterwards.

Lettuce: overall, 18 residue dissipation trials with BYI 02960 were available for lettuce. In 13 of these trials, the residue dissipation could be considered according to SFO, whilst the remaining 5 trial results needed fitting with DFOP. Furthermore, one trial provided an SFO-DT50 value after the first application and an DFOP-DT50 after the second application. Since the (single) DT50 from SFO fits cannot simply be averaged with the (double) DT50 from DFOP fits, calculations of the 21-d fTWA were conducted for each of the trials, and the 17 resulting 21-d fTWA values were combined afterwards (for each trial the value after the second application was taken). Due to the number of trials in the evaluation it is proposed to use the geometric mean 21-d fTWA = 0.17 for the refined long-term exposure assessment for small herbivorous mammals in lettuce fields (Table 2.6.1.2-09).

Geometric mean 21-d f_{TWA} (only ftwa values after second application included)					**0.17**

However, some uncertainty remains on whether this value is applicable to the full application period. In the GAP, application in lettuce is proposed between BBCH 12-49. The notifier states that the inclusion of the evaluation of some residue decline after the first application and the fact that there is no large difference between the decline after the first and the second application, addresses the question of potential impact of the application stage on the decline curves. To investigate this statement, RMS checked the lettuce trials to see at which BBCH-stages they were performed. See 2.6.1.2-10.

Table 2.6.1.2-10 BBCH stages at application in lettuce trials (shaded trials were analysed both after the first and after the second application)

R17	10-2071-04	17	49

The table shows that only one of the four doubly analysed trials was performed at a relatively early BBCH stage. In the view of the RMS, this is not enough proof that the residue decline trials really cover also early application stages (from BBCH 12). If these data are used in a refined risk assessment, this issue should be addressed further.

Cereals as surrogate for undergrowth in hop yards: overall, 4 residue dissipation trials with BYI 02960 were available for young cereals. In 3 of these trials, the residue dissipation could be considered according to SFO, whilst in the remaining trial results needed fitting with DFOP. Since the (single) DT50 from SFO fits cannot simply be averaged with the (double) DT50 from DFOP fits, calculations of the 21-d fTWA were conducted for each of the trials, and the 4 resulting 21-d fTWA values were combined afterwards. Due to the number of trials in the evaluation it is proposed to select the median 21-d fTWA = 0.15 for the refined long-term exposure assessment for small herbivorous mammals feeding on undergrowth in hop yards (Table 2.6.1.2-11). The trials were performed at BBCH 25-29, meaning that the cereal plants were in the tillering stage. RMS considers this reasonably representative for the grass that is expected to form the undergrowth vegetation of hop plantations.

Table 2.6.1.2-11a DT$_{50}$ and 21-d f$_{TWA}$ for residue dissipation of total flupyradifurone on young cereals

Trial code	Trial description	SFO DT$_{50}$	DFOP DT$_{50\ fast}$	DFOP DT$_{50\ slow}$	21-d f$_{TWA}$
R01	11-2958-01, N-EU	-	0.145	3.555	0.0649
R02	10-2958-02, N-EU	1.44	-	-	0.10
R03	10-2958-03, N-EU	4.22	-	-	0.28
R04	10-2958-04, S-EU	3.15	-	-	0.21
Median 21-d f$_{TWA}$					**0.15**

The two residue data sets result in very similar 21-d f$_{TWA}$ values (0.17 and 0.15).
~~However, the residue decline data are not used, because based on the NOEAL of 34 mg/kg bw/d, a refined risk assessment is not necessary.~~

Expert consultation during Pesticide Peer Review meeting 124, ecotoxicology, December 2014:

The approach described above, for deriving overall ftwa values from the lettuce and cereal trials, was discussed in the expert meeting. It was questioned whether the approach taken by the RMS was reasonable as a refinement. The studies performed on lettuce were questioned as food items could be weeds including monocots. The RMS highlighted that trials on cereals were also available and the difference in the fTWA was minor indicating not too dissimilar speed of degradation/dissipation. It was noted that 18 trials were available for lettuce and only 4 for cereals. It was discussed whether the scenarios in the GD cover mammals consuming the lettuce crop plants in addition to weeds. Experts noted that different FIR would be needed for a lettuce scenario. The experts agreed that, when refining the assessment, the food items taken by the focal species should be considered.

The representativeness of the studies used was discussed noting that the studies were not performed at the correct growth stage. The lettuce trials were performed at BBCH 17 to 46 whereas the GAP is BBCH 12 to 49 (lettuce). The RMS considered this in the DAR and noted that the lettuce trials do not cover the entire GAP for lettuce. Furthermore, the RMS noted during the meeting that it could be that at later growth stages the dissipation is slower due to slower growth. Some experts did not consider the BBCH stage of the crop to be an issue as the studies should represent weeds in addition to the crop. Furthermore, the DT50 in the two types of trials were not too dissimilar.

The cereal trials were performed at BBCH 25 to 29 and therefore were at a growth stage palatable to birds and mammals. The RMS considered that this was reasonable to represent weeds. The fTWA from both trials were comparable regardless of the growth stage further supporting the use of the studies.

Overall the experts agreed that the available studies were suitable to be used for the refined assessment for the representative uses.

It was discussed how the fTWA values should be used in the risk assessment (geomean, pooled, lower, two assessments). The geomean was questioned as it does not result in a worst case value but then the RMS noted that there were more than ten values indicating that the geomean was reasonable (NL approach). The RMS also noted that the studies needed to cover the entire EU. Some studies were performed in NEU and SEU, no differences were noted. Overall, the experts considered that the data were sufficient for N and SEU. The RMS suggested that the data could be pooled and then the geomean from the pooled data used. The experts noted that pooling data should be done with care and therefore it is difficult to agree on the basis of the available raw data. It was agreed that the RMS should pool the data but check statistically significant differences between the two data sets (lettuce crop vs. cereals and N vs. SEU) whether the pooled data are ok. If so, then the geomean can be taken. If not, then the experts considered that separate risk assessments may be required.

It was agreed that the data was suitable for all weed types and lettuce crop plants given that the data cover monocots and dicots and that the DT50 may not depend on the structure of the plant.

On the basis of the above, the RMS needs to update the risk assessment using the appropriate fTWA.

It was noted that the approach in which the 21-d ftwa is calculated from measurements which started at the last application (in trials with two applications) is acceptable for the current GAP, since this has only one application per year. It was discussed that it may not cover GAPs which have multiple applications, as the 21-d exposure window may be higher at an earlier stage. Therefore, for other GAPs it needs to be carefully considered how to use these data.

The differences between the data sets were checked by the RMS (t-test, unequal variance, two-sided): lettuce N-lettuce S; cereal N- cereal S (note that only four trials were available here so this exercise is less useful); all trials lettuce-cereals; all trials N-S. Result: P>0.1 in all cases. Therefore, the data can be pooled and the overal geometric mean can be taken for all weed types and lettuce crop plants. Thus, in the refined risk assessment for the small herbivorous mammal “vole”, an ftwa of 0.164 can used for the representative uses.

The shortcut value which was used in the first tier calculation is calculated as SV = FIR/bw * deposition factor * RUD. In the first tier table from the EFSA GD (Appendix A), the shortcut value for the “vole” in “leafy vegetables” at BBCH 40-49 is 72.3. This is derived as follows:

FIR/bw = 1.33 (based on 100% grass intake and 25 g body weight)

Deposition factor = 1 for lettuce (no interception), 0.3 for hops (70% interception)

RUD = 54.2 (default RUD from “grass + cereal” database).

In the refined risk assessment, it needs to be considered if these values are still appropiate.

The deposition values are dependent on crop stage and therefore still relevant. Note that for lettuce, interception should not be taken into account at any stage for the part of the diet that consists of crop plants.

The “vole” foraging in lettuce fields may feed on all types of plants, not only grass. The FIR/bw for a 25 g mammal feeding 100% on ‘non-grass herbs’ is 1.61 (calculated according to Appendix G). Therefore, the first tier FIR/bw of 1.33 may slightly underestimate the risk. However, the default RUD value for the food category “non-grass herbs” is 28.7, which is almost half that of “grass”. Therefore, the calculations based only on 100% “grass” intake are clearly worst-case even though the diet composition of the “vole” in lettuce fields is not known, and as long as the default RUDs are used it is not necessary to use a different FIR/bw in the refined calculations.

Table 2.6.1.2-11c Refined long-term DDD and TER_{LT} calculation for the "vole"

Crop	Generic focal species	NOAEL [mg/kg bw/d]	DDD				DDD	TER_{LT}	Trigger
			Appl. rate [kg/ha]	SV_m	MAF_m	f_{TWA}			
BYI 02960									
Hops (≥ 40)	Small herbivorous mammal "vole"	6.4	0.150	21.7	1	0.164	0.53	12	5
Lettuce (40-49)	Small herbivorous mammal "vole"	6.4	0.125	72.3	1	0.164	1.48	**4.3**	5

Bold values do not meet the trigger

The refined TER value for the use in hops is above the trigger, indicating acceptable risk. For the use in lettuce the TER is below the trigger. The applicant provided a statement to address the risk.

Relevance of the "vole" scenario in hops and lettuce fields

The notifier submitted a statement which is presented without modifications below. Please note that the TER values are based on the worst-case endpoint of 7.8 mg/kg bw/d.

"*The risk to wild mammals from the use of BYI 02960 has been evaluated according to the Tier 1 scenarios provided in the EFSA GD. These scenarios include small insectivorous mammals ("shrew"), small omnivorous mammals ("mouse"), large herbivorous mammals ("lagomorph"), and small herbivorous mammals ("vole").*

*Whilst all other scenarios demonstrated adequate margins of safety, even with the worst case settings of a Tier 1 assessment, the scenario "vole" resulted in Tier 1 TERLT values of 4.5 and 1.6 for the uses in hop and lettuce, respectively. These Tier 1 TERLT values for voles exceed a threshold of 1, indicating that some margins of safety exist even under the worst case settings applied at Tier 1. Quantitative refinement elements (refined reproductive risk assessment endpoint 39.23 mg/kg/bw/d; measured residue decline DT50 resulting in 21-d fTWA = 0.19) that have been introduced above allow a re-calculation of the Tier 2 TERLT values that include margins of safety clearly in excess of the a-priori acceptability trigger of 5 (*values not shown here*).*

Thus, a quantitative refinement at the level of individual exposure and risk can be conducted to demonstrate acceptable risk at the level of individual voles.

However, the protection goal in ecotoxicology aims ultimately at protection of populations rather than individuals. Therefore the section below is intended to additionally evaluate the risk to vole populations from exposure to BYI 02960 after application in hop or lettuce fields. This evaluation is based on the well known biology and ecology of Common voles (Microtus arvalis) as the representative species "behind" the generic focal species scenario "vole", and complemented with a targeted field study in hop yards.

Exposure of Populations

The optimum or prime habitat of the common vole requires permanent vegetation cover and includes grassland or perennial crops such as alfalfa and clover fields. Common voles also occur in sub-optimal (secondary) habitats such as arable land. However, only prime habitats harbor permanent vole populations and are essential for the survival of common vole populations. Secondary habitats are only transiently populated, with regular population declines up to extinction during agronomic operations (e.g., ploughing or harvest), or over winter.

Wherever the species occurs; the population densities of Common voles vary seasonally, with regular mass occurrences being followed by a population break-down which can even lead to local extinction.

Spring crops like lettuce fields are not populated during winter, would not provide much cover against predation and could thus be colonized only from adjacent prime habitats at times of high population density. Spring sown vegetable fields would therefore not belong to the potential prime habitats of Common voles (e.g. Spitz, 1977[5]).

A field study conducted in hop yards in Germany (KIIIA1 10.3.3/01) also confirms that the treated area does not harbor significant proportions of the local vole populations.

Thus, any effect from exposure of voles in areas treated with BYI 02960 would be of low, if any, importance on the local population level which depends on the voles living outside of the lettuce fields or the hop yards.

Vulnerability of populations:

The failure to demonstrate TERLT > 5 for voles is not a rare event, due to the worst case combination of factors involved in the scenario. Actually, in regard of theoretical exposure of individual animals, the vole scenarios are nearly always the most critical all over the EFSA GD (2009). However, with regard of the vulnerability of vole populations, the vole scenario is probably the least critical.

The Joint Working Group on the Guidance Document on Risk Assessment for Birds & Mammals (SANCO 10997/2009) has already raised the question on the "need for the vole scenario… given the resilience of the vole populations"; i.e. well-known fact that voles are able to recover after large population breakdowns, or despite eradication programs with targeted rodenticide use (for recent evaluations see e.g.. Jacob & Tkadlec 2010[6], or Jokic et al. 2010[7]).

---

[5] Spitz F (1977), Le campagnol des champs (*Microtus arvalis* (Pallas)) en Europe. EPPO Bulletin 7:156-175. BCS Edition no. M-228600-01-1

[6] Jacob & Tkadlec (2010), Rodent outbreaks in Europe: dynamics and damage. In:Singleton et al. (Eds): Rodent outbreaks: Ecology and Impacts.,p: 217-233. BCS Edition no: M-427173-01-1

This potential for recovery of Common voles is extraordinarily large, due to the ability of Common voles to achieve high population numbers within short periods of time thanks to the reproduction biology of the species (e.g. Lauenstein 1979[8], Jacob 2003[9]):

- *the potentially highest number of young per litter ranges between 12 and 13. The weight of a litter is about 53% of the females weight*
- *average number of young per litter in the field is about 7*
- *gestation period is about 20 days in the field*
- *successful mating occurs when young females are not yet weaned*
- *long reproduction period including occasional winter reproduction*

The most straightforward application of the conclusion by the Joint Working Group on the Guidance Document on Risk Assessment for Birds & Mammals (SANCO 10997/2009) (questioning the "need for the vole scenario… given the resilience of the vole populations)" would be that the failure to meet the a-priori acceptability trigger for long-term exposure of individual voles is not to be considered as problematic as long as the TER trigger for the other wild mammal scenarios reach the respective TER trigger.

This is clearly the case for exposure of wild mammals to BYI 02960.

Small herbivorous mammals in hops

A targeted field study has been conducted in hop yards in Germany (KIIIA1 10.3.3/01).

Live trapping revealed that hop yards do not harbor significant proportions of small herbivorous mammals (Common vole, Field vole or Bank vole), as only 0.09% (3 of 3272) of the individuals of the local vole populations was recorded in-field. Radio-tracking confirmed that voles make very little use of hop yards as feeding habitat. Only one of 10 voles (1 of 5 common voles) potentially spent foraging time in a hop yard. This individual was only trapped once, thus considered a disperser rather than part of a local in-field population.

Overall the results of the study do not confirm that the generic focal species scenario of "small herbivorous mammals (vole)" provided in the EFSA GD 2009 would be relevant for hop yards. To the contrary, a very low number of individual voles (< 0.1%) would be exposed on hop yards and the risk on local populations from effects on these individuals would be negligible.

Small herbivorous mammals in leafy vegetables

The prime habitat of voles is grassland but the species can also be found in cultivated areas. Stable populations can be developed in multi-annual crops, particularly clover/alfalfa fields which perfectly

[7] Jokic G, Vuksa P & Vuksa M (2010), Comparative efficacy of conventional and new rodenticides against Microtus arvalis (Pallas, 1778) in wheat and alfalfa crops. Crop Protection 29: 487-491. BCS Edition no: M-427179-01-1

[8] Lauenstein G (1979), Zur Problematik der Bekämpfung von Feldmäusen (Microtus arvalis Pall.)) auf Grünland. Zeitschrift für angewandte Zoologie 66: 35-59. BCS Edition no M-419441-01-1

[9] Jacob J (2003), Short-term effects of farming practices on populations of common voles. Agriculture, Ecosystems and Environment 95: 321-325. BCS Edition no. M-415511-01-1

match the species ecological needs. Whilst autumn sown fields might serve as overwintering habitat, spring sown fields would only be colonized later in the season (summer) and only during periods of high population density, then representing rather a "sink" than a "source" habitat for the local populations). "

Response RMS: The first tier risk assessment based on the ecologically relevant endpoint of 34 mg/kg bw/d was acceptable in the original DAR, so the public literature referred to was not evaluated. The monitoring trial in hop fields was however evaluated above (Study IIIA, 10.3.3/01).
The live trapping of mammals showed that they preferred the natural habitats instead of the hop yard. The wood mouse was the most abundant species inside the hop yard and was the only species tracked regularly inside the hop yard. Five common voles were radiotracked; one of those spent all its time in the hop yard. This individual, a fertile male, used the habitat hop yard and spent 100% of the 24 h telemetry in it. This individual seemed to be a so-called disperser trapped on study site 4, it was the only common vole trapped on this site. In late July the undersown crops Raphanus sativa, Galinsoga spec, and Chenopodiaceae were already high and therefore the predation risk inside the hop yard decreased. The population densities of common voles in the surroundings in late July was high and the need for new territories increased. These factors indicate that this individual was migrating and used the hop yard not as a sustainable habitat. However, this finding means that common voles can use hop fields as feeding habitat, at least occasionally. Therefore, RMS does not agree with the notifier that the study shows that the common vole is not a relevant species in hop fields.
It should also be noted that the results from this study (for both mammals and birds) are based on hop yards close to nature areas. It is not clear if the same focal species can be used for hop yards in an intensively cultivated area, if present at all. Mammal trapping was only conducted in the hop yards close to nature, therefore it is not possible to compare species abundance between plots in intensively cultivated area and plots close to nature areas.
If the study is used in a refined risk assessment, these remarks should be taken into account.

Furthermore, in case of higher tier, EFSA (2009) requires an uncertainty analysis of the refinements (see 6.8 and 6.9).This is however not available in the dossier. Should a refined risk assessment become necessary (e.g. by change of the endpoint after peer review), an uncertainty analysis should be provided, in the tabular form recommended by EFSA.

Based on the new long-term endpoint for mammals, the TER for the small herbivorous mammal "vole" from the use of the a.s. in lettuce is 4.3, which is below the trigger of 5. The notifier questions the relevance of the "vole" scenario in general. This issue should be considered by a dedicated EFSA working group or the PPR panel. As long as the guidance document includes the vole scenario, it has to be taken into account. Non-relevance of a species (group) can be shown with field monitoring data,

but these are not available for mammals in lettuce fields. Population effects can be investigated with field effect data and/or population modelling, but these are not available either. Based on the available data, a risk to the "vole" cannot be excluded. It is noted that the TER is not far below the trigger, that the only refinement included is one on residue dissipation, that the TER is calculated with the lowest available long-term endpoint which is based on <10% lower bodyweight at the next level, and that the diet composition use in the calculations is worst-case.

Metabolites

The notifier provided the following information: " The toxicological properties of two metabolites of BYI 02960 were investigated in a series of studies and evaluated in more detail in section KIIA 5.8 of this submission. Toxicological studies performed on two other metabolites which are also common metabolites to other agrochemicals are also reported in this section. Only a brief summary of the results of these studies is presented in this section. Overall, the results indicate that none of the metabolites is more toxic to mammals than the parent, so that the risk assessment for wild mammals can be based on the toxicity and exposure ratios calculated for BYI 02960 a.i.

The metabolite difluoroacetic acid (DFA) is a major soil, water and plant metabolite and is found in the rat ADME study at an amount of around 6%. It is considered a non-relevant metabolite in terms of the EU Guidance document Sanco/221/2000-rev.10 (25 February, 2003). This metabolite was devoid of genotoxic potential; the acute oral LD50 was between 300 and 2000 mg/kg. When DFA was administered via the diet to Wistar rats for at least 14 days at concentrations of 500, 2000 and 8000 ppm (equating approximately to 48, 187 and 745 mg/kg body weight/day, respectively in males and 51, 201 and 800 mg/kg body weight/day, respectively in females), slight body weight decrease was observed in both sexes at 8000 ppm. In a 90-day rat study, DFA was administered in the diet administration to Wistar rats at concentrations of 200, 1000 and 6000 ppm (equating approximately to 12.7, 66.2, 380 mg/kg body weight/day, respectively in males and 15.6, 78.7, 472 mg/kg body weight/day, respectively in females). Mean body weight and food consumption were reduced at 6000 and 1000 ppm, respectively in both sexes but not at 200 ppm. When the NOAEL of 200 ppm DFA is expressed in BYI 02960 equivalents, it equates to 38 and 47 mg/kg/day in males and females, respectively. Therefore, DFA was not more toxic than BYI 02960 after subchronic administration to the rat.

BYI 02960-difluoroethyl-amino-furanone (DFEAF) is a minor plant metabolite. The acute oral LD50 in rats was higher than 2000 mg/kg, indicating that DFEAF is not more toxic than BYI 02960.

BYI 02960-CHMP ((6-chloro-3-pyridyl)methanol) is a plant metabolite. The acute oral rat LD50 was 1842 mg/kg in males and 1483 mg/kg in females. In a 90-day rat study, BYI 02960-CHMP was administered in the diet to Sprague Dawley rats (10/sex/group) at concentrations of 160, 800, 4000 and 20 000 ppm, (corresponding to 9.9, 48.9, 250.1 and 1246.6 mg/kg/day, respectively for males and 11.1, 55.9, 275.9 and 1173.7 mg/kg/day, respectively for females). Mean body weights and mean food consumption were decreased at 20000 ppm in both sexes. Based on eosinophilic intranuclear

inclusions in the proximal tubular epithelium of kidneys at 20000 ppm and 4000 ppm, the no observed effects level (NOEL) was 800 ppm (48.9 mg/kg/day) in males, and 4000 ppm (275.9 mg/kg/day) in females, respectively. When the NOEL is expressed in BYI 02960 equivalents, it equates to 97.8 and 551.8 mg/kg/day, respectively. Therefore, BYI 02960-CHMP was less toxic than BYI 02960 after subchronic administration to the rat.
6-CNA (6-chloronicotinic acid) is a major soil and plant metabolite. An acute oral rat toxicity study and an Ames test were performed on this metabolite for the registration of acetamiprid. 6-CNA was not genotoxic and not acutely toxic."
RMS agrees that no separate risk assessment is required for the metabolites.

Exposure via drinking water

An assessment of the risk potentially posed by consumption of contaminated drinking water is required according to the EFSA Guidance Document for Birds and Mammals (2009).
Two scenarios were identified as relevant for assessing the risk of pesticides via drinking water to birds and mammals:

- Leaf scenario, only relevant for birds possibly drinking water from puddles in leaf whorls after application of a pesticide to a crop and subsequent rainfall or irrigation; not relevant for mammals.
- Puddle scenario. Birds and mammals taking water from puddles formed on the soil surface of a field when a (heavy) rainfall event follows the application of a pesticide to a crop or bare soil. This scenario is relevant for all types of applications that may cause contamination of soil and only for long-term exposure. A risk assessment is performed below.

<u>Risk assessment for the puddle scenario (field use in hop and lettuce):</u>

An "escape clause" recommended in the EFSA Guidance Document for Birds and Mammals (2009) allows for screening the need for a quantitative risk assessment by a comparison between the application rate and the toxicity of the respective substance. This escape clause specifies that "*due to the characteristics of the exposure scenario in connection with the standard assumptions for water uptake by animals …, no specific calculations of exposure and TER are necessary when the ratio of effective application rate (= application rate x MAF) (in g/ha) to relevant endpoint (in mg/kg bw/d) does not exceed 50 in the case of less sorptive substances (Koc < 500 L/kg) or 3000 in the case of more sorptive substances (Koc ≥ 500 L/kg).*" [10].

Table 2.6.1.2-12 Evaluation of potential concern for exposure of mammals drinking water from puddles (escape clause)

[10] EFSA (2009): Guidance Document on Risk Assessment for Birds & Mammals on request from EFSA, p. 66

Compound	Koc [mL/g]	Application rate * MAF [g a.i./ha]	LD50 or NO(A)EL [mg a.i./ kg bw/d]	Ratio (Application rate * MAF) / NO(A)EL	"Escape clause" No concern if ratio	Conclusion
BYI 02960	98.4 [1)]	150 [2)] x 1	1607	0.09	≤ 50	No concern
			~~34~~ 6.4	~~4.4~~ 23	≤ 50	No concern

1) Arithmetic mean of ten K_{OC} values (see B.5)

2) Worst-case application rate in hops

This evaluation confirms that the risk for mammals from drinking from puddles that may contain residues from the use of product is acceptable.

Indirect exposure via contaminated worms or fish

Substances with a high bioaccumulation potential could theoretically bear a risk of secondary poisoning for mammals if feeding on contaminated prey like fish or earthworms. For organic chemicals, a log POW > 3 is used to trigger an in-depth evaluation of the potential for bioaccumulation. As shown, neither the active ingredient nor any of its metabolites has a log Pow above 3 and the potential of bioaccumulation is considered to be very low. Hence, there is no need to evaluate potential effects of secondary poisoning of mammals.

2.6.2 Effects on aquatic species

Summary of aquatic toxicity data

Active substance and formulation

The active ingredient of BYI 02960 SL200, BYI 02960, has been tested on all laboratory indicator species for aquatic organisms representing all trophic levels of the aquatic environment. Acute data on fish toxicity are available for four different species, amongst them the sensitive cold water fish trout, and the salt water fish *Cyprinodon variegatus*. The results indicate that BYI 02960 is practically non-toxic to fish. As such, the LC50 values reported are greater than the highest concentration within the test. Using the formulated product BYI 02960 SL 200G the LC50 as related to the active substance was >100 mg a.i./L.

An early life-stage test for BYI 02960 confirms the low toxicity to fish also on chronic scale. Exposed continuously over the full developmental life-phase of fathead minnow a slightly reduced fry survival at the highest test concentration of 10 mg a.i./L was recorded. As compared to the untreated control survival was reduced by 7% resulting in an overall fry survival of 87.5% at a mean measured

concentration of 8.4 mg a.i./L. Time to hatch and hatching success was not influenced, neither was any effect observed on growth as determined on length and weight.

A very selective non-target activity of BYI 02960 is further confirmed by low toxicity to representatives of three other taxonomic groups, namely amphibians, algae and aquatic plants. There were no adverse effects noted in the 48h acute frog test, and the influence of the active substance on *Pseudokirchneriella subcapitata* and *Lemna gibba* was also negligible. In a test with the formulation no effects on algal development were recorded at the highest test concentration used 250 mg formulation/L corresponding to 42.5 mg a.i./L. For Lemna, an onset of effects was determined at a mean measured concentration of 67.7 mg a.i./L ; therefore aquatic plants are also considered to be insensitive to the active substance.

BYI 02960 is an insecticide against sucking insects. Hence, a side activity against aquatic invertebrates can be anticipated. Data were generated on all laboratory standard indicator species of aquatic arthropods: the cladoceran *Daphnia magna*, the midge *Chironomus riparius* and, the marine species *Americamysis bahia* and the mollusc *Crassostrea virginica*. The most sensitive organism for BYI 02960 was found to be *Chironomus riparius*. While acute toxicity to daphnids was negligible with a NOEC for the active substance at or greater than 77.6 mg a.i./L, the 50% effect concentration (EC50) to the midge was determined to be at a concentration of 0.062 mg a.i./L. For the saltwater species, the LC50 of the mysid shrimp was at 0.26 mg a.i./L and indicates as such a lower sensitivity than the insect. BYI 02960 was non-toxic to the marine oyster.

Chronic tests confirm the high toxicity of the active substance to *Chironomus riparius*. The lowest-observed-effect concentration (LOEC) impacting the emergence of the developed Chironomus larvae was at ~~0.02~~ 0.015 mg a.i./L, only a factor of ~~3~~ 4 below the acute EC50 values. The acute-to-chronic ratio for the most sensitive ecotoxicological endpoint, survival of Chironomus, for BYI 02960 is thus low. The immediate activity observed in the acute test appears to be reflected in the chronic test.

The 28 day chronic mysid shrimp test resulted in a LOEC of 0.0236 mg a.i./L based upon a statistically significant influence on reproductive output. The notifier considers that from the first-tier laboratory test species indicative for a potential effect of an insecticide, Chironomus is considered to be of higher relevance for the risk assessment than the marine shrimp as it reflects a real taxonomic group present in the freshwater biocoenosis. The influence of the formulation BYI 02960 SL 200 G was therefore examined on Chironomus as the most sensitive invertebrate. The lowest-observed-effect concentration was at ~~0.024~~ 0.020 mg a.i./L, the NOEC was established at ~~0.012~~ 0.00989 mg a.i./L.

However, RMS does not accept to disregard the mysid shrimp data. Saltwater species are always included in the risk assessment unless a clear difference in sensitivity is observed between saltwater and freshwater species and it can be proven that exposure of saltwater environments is not relevant. In this case, the mysid shrimp NOEC is 0.0132 mg a.i./L and therefore close to the Chironomus endpoint. Hence, it is not considered acceptable to disregard the data available for the mysid shrimp. However, the Chironomus endpoint is driving the risk assessment since it is slightly lower.

In general, there was no relevant influence of the formulation on the toxicity in comparison to the toxicity with the active substance.

Accepted data on the acute toxicity of BYI 02960 (flupyradifurone) and BYI 02960 200 SL (Sivanto) are summarised in Table 2.6.2-01. In the tables, it is indicated whether endpoints are based on nominal or actual concentrations. Data indicated in bold are the lowest effect concentrations for that species group.

Table 2.6.2-01. The acute toxicity of BYI 02960 and BYI 02960 SL 200 to aquatic life. Bold data are the lowest effect concentrations for that specific group.

Group	Test substance	Time-scale (Test type)	End point	Toxicity[1] (mg/L)

Metabolites

According to the LoEP from fate and behaviour, the environmental occurring metabolites requiring further assessment by other disciplines (toxicology and ecotoxicology) are:

Surface Water: 6-CNA, DFA, BYI 02960-succinamide, BYI 02960-azabicyclosuccinmaide

Sediment: 6-CNA, DFA

Accepted acute data on the acute toxicity of the relevant metabolites are summarized in Table 2.6.2-02.

Risk assessment

The risk assessment is based on Guidance Document on Aquatic Ecotoxicology, SANCO/3268/2001, rev 4 final, 17 October 2002. Toxicity exposure ratios (TER values) are calculated based on the most sensitive species and worst-case PEC_{SW} values.

The TER-values have been calculated based on the following equations:

TER_A = LC50 or EC50 / maximum PEC_{SW}

TER_{LT} = ErC50 / maximum PEC_{SW}

TER_{LT} = chronic NOEC /maximum PEC_{SW}

The risk is considered acceptable if the TER_A values are ≥ 100, and the TER_{LT} values ≥ 10.

Acute and chronic risk assessment was carried out in tier 1 using the initial PEC_{SW} calculated with FOCUS Surface Water, Step 2, and the lowest available toxicity endpoints for algae, *Daphnia* and other invertebrates, fish, amphibians, and *Lemna*. The resulting TER-values are presented for the

different uses of BYI 02960 SL 200 for the a.s. and the metabolites. TERs that do not meet the relevant trigger are indicated in bold.

Tier 1 risk assessment for fish (and other aquatic vertebrates)

The acute risk assessment for the a.s. is based on the lowest LC50 for fish of >70.5 mg a.s./L; this also covers amphibians since the LC50 for *Xenopus laevis* is higher (>80 mg a.s./L).

Table 2.6.2-05 TER_A calculations for fish based on FOCUS Step 2 for application in hops

Compound	Species	Endpoint [µg/L]		$PEC_{sw,max}$ [µg/L]	TER_A	Trigger
Crop: Hops						
BYI 02960	*P. promelas*	LC_{50}	**>** 70 500	17.36	> 4 061	100
BYI 02960 – succinamide	*O. mykiss*	LC_{50}	**>** 100 000	4.065	> 24 600	
DFA*	*O. mykiss*	LC_{50}	> 10 000	1.268 (1.421*)	>7 886 (> 7 037*)	

*) In a worst-case approach, exposure concentrations for DFA are based upon groundwater calculations; however, dilution will occur during transport to surface waters.

Table 2.6.2-06 TER_A calculations for fish based on FOCUS Step 2 for application in lettuce – biennial (covers annual use)

Compound	Species	Endpoint [µg/L]		$PEC_{sw,max}$ [µg/L]	TER_A	Trigger
Crop: Lettuce						
BYI 02960	*P. promelas*	LC_{50}	**>** 70 500	11.88	> 5 934	100
BYI 02960 – succinamide	*O. mykiss*	LC_{50}	**>** 100 000	0.484	> 206 612	
DFA*	*O. mykiss*	LC_{50}	> 10 000	1.339 (5.599*)	> 7 468 (> 1 786*)	

*) In a worst-case approach, exposure concentrations for DFA are based upon groundwater calculations; however, dilution will occur during transport to surface waters.

The TERA values meet the required trigger for both uses, indicating an acceptable acute risk to fish for application of the product.

Table 2.6.2-07 TER_{LT} calculations for fish based on FOCUS Step 2 for application in hops

Compound	Species	Endpoint [µg/L]		$PEC_{sw,max}$ [µg/L]	TER_{LT}	Trigger
Crop: Hops						
BYI 02960	*P. promelas*	NOEC	4410	17.36	254	10

Table 2.6.2-08 TER_{LT} calculations for fish based on FOCUS Step 2 for application in lettuce – biennial (covers annual use)

Compound	Species	Endpoint [µg/L]		$PEC_{sw,max}$ [µg/L]	TER_{LT}	Trigger
Crop: Lettuce						
BYI 02960	*P. promelas*	NOEC	4410	11.88	371	10

The TER_{LT} values meet the required trigger for both uses, indicating an acceptable long-term risk to fish for application of the product.

Tier 1 risk assessment for aquatic invertebrates (including sediment-dwelling organisms)

The acute risk assessment for the a.s. is based on the lowest LC50 for aquatic invertebrates of 0.0617 mg a.s./L, for *Chironomus*. Sediment-spiked tests with *Chironomus* are not available, therefore the risk assessment is performed with PECsw only (so PECsed is not used).

Table 2.6.2-09 TER_A calculations for aquatic invertebrates based on FOCUS Step 2 for application in hops

Compound	Species	Endpoint [µg/L]		$PEC_{sw,max}$ [µg/L]	TER_A	Trigger
Crop: Hops						
BYI 02960	*C. riparius*	EC_{50}	61.7	17.36	**3.53**	100
DFA*	*D. magna*	EC_{50}	**>** 10 000	1.268 (1.421*)	> 7 886 (> 7 037*)	
6-CNA	*D. magna*	EC_{50}	> 95 100	0.463	> 205 400	

*) In a worst-case approach, exposure concentrations for DFA are based upon groundwater calculations; however, dilution will occur during transport to surface waters.

Table 2.6.2-10 TER_A calculations for aquatic invertebrates based on FOCUS Step 2 for application in lettuce – biennial (covers annual use)

Compound	Species	Endpoint [µg/L]		$PEC_{sw,max}$ [µg/L]	TER_A	Trigger
Crop: Hops						
BYI 02960	*C. riparius*	EC_{50}	61.7	17.36	**3.53**	100
DFA*	*D. magna*	EC_{50}	> 10 000	1.268 (1.421*)	> 7 886 (> 7 037*)	
6-CNA	*C. tentans*	EC_{50}	> 1 000	0.463	> 2 160	
BYI 02960-succinamide	*C. riparius*	EC_{50}	> 100 000	4.065	> 24 600	
BYI 02960-azabicyclosuccinamide, sodium salt	*C. riparius*	EC_{50}	> 100 000	2.499	>40 016	

*) In a worst-case approach, exposure concentrations for DFA are based upon groundwater calculations; however, dilution will occur during transport to surface waters.

The TERA values meet the required trigger for both uses for the metabolites, indicating an acceptable acute risk to aquatic invertebrates. However, for the acute risk of the a.s., refinement is required.

The long-term risk assessment for the a.s. is based on the lowest NOEC for aquatic invertebrates of ~~0.0102~~ 0.00681 mg a.s./L, for *C.riparius*.

Table 2.6.2-11 TER_{LT} calculations for aquatic invertebrates based on FOCUS Step 2 for application in hops

*) In a worst-case approach, exposure concentrations for DFA are based upon groundwater calculations; however, dilution will occur during transport to surface waters.

Table 2.6.2-012 TER_{LT} calculations for aquatic invertebrates based on FOCUS Step 2 for application in lettuce - biennial (covers annual use)

Compound	Species	Endpoint [µg/L]		$PEC_{sw,max}$ [µg/L]	TER_{LT}	Trigger
Crop: Lettuce						
BYI 02960	*C. riparius*	NOEC	~~10~~ 6.81	11.88	~~**0.84**~~ **0.57**	10
BYI 02960 – succinamide	*D. magna*	NOEC	43 300	0.484	89 463	
DFA*	*C. riparius*	NOEC	100 000	1.339 (5.599*)	74 683 (17 860*)	
6-CNA	*C. riparius*	NOEC	100 000	0.579	172 712	

*) In a worst-case approach, exposure concentrations for DFA are based upon groundwater calculations; however, dilution will occur during transport to surface waters.

The TERLT values meet the required trigger for both uses for the metabolite, indicating an acceptable long-term risk to aquatic invertebrates. However, for the long-term risk of the a.s., refinement is required.

Tier 1 risk assessment for algae

The risk assessment for the a.s. is based on the lowest EC50 for algae of >42.8 mg a.s./L, based on the study with the formulated product.

Table 2.6.2-13 TER_A calculations for algae based on FOCUS Step 2 for application in hops

Compound	Species	Endpoint [µg/L]		$PEC_{sw,max}$ [µg/L]	TER_A	Trigger
Crop: Hops						
BYI 02960	*P. subcapitata*	EC50	>42 800	17.36	>2 465	10
DFA	*P. subcapitata*	EC50	>10 000	1.268	>7 886	10
BYI 02960 – succinamide	*P. subcapitata*	EC50	>10 000	4.065	>2 460	10
6-CNA	*P. subcapitata*	EC50	85 000	0.463	183 585	10

Table 2.6.2-14 TER_A calculations for algae based on FOCUS Step 2 for application in lettuce – biennial (covers annual use)

Compound	Species	Endpoint [µg/L]		$PEC_{sw,max}$ [µg/L]	TER_A	Trigger
Crop: Lettuce						
BYI 02960	*P. subcapitata*	EC50	>42 800	11.88	>3 603	10
DFA	*P. subcapitata*	EC50	>10 000	1.339	>7 468	10
BYI 02960 – succinamide	*P. subcapitata*	EC50	>10 000	0.484	>20 661	10
6-CNA	*P. subcapitata*	EC50	85 000	0.579	146 805	10

The TERA values meet the required trigger for both uses for the a.s. and the metabolites, indicating an acceptable risk to algae.

Tier 1 risk assessment for aquatic macrophytes

Table 2.6.2-15 TER_A calculations for lemna based on FOCUS Step 2 for application in hops

Compound	Species	Endpoint [µg/L]		$PEC_{sw,max}$ [µg/L]	TER_A	Trigger
Crop: Hops						
BYI 02960	*L. gibba*	EC50	>67 700	17.36	>3 890	10

Table 2.6.2-16 TER_A calculations for lemna based on FOCUS Step 2 for application in lettuce –biennial (covers annual use)

Compound	Species	Endpoint [µg/L]		$PEC_{sw,max}$ [µg/L]	TER_A	Trigger
Crop: Lettuce						
BYI 02960	*L. gibba*	EC50	>67 700	11.88	>5 699	10

The TERA values meet the required trigger for both uses for the a.s., indicating an acceptable risk to algae.

Refined risk assessment for aquatic invertebrates

Based on the tier 1 risk assessments shown above, acceptable risk is found for the a.s. for fish and other aquatic vertebrates, algae and aquatic macrophytes.
For the relevant metabolites, sufficient toxicity data are available. Acceptable risk is found for all groups.
However, refinement is necessary for the a.s. for the acute and long-term risk to aquatic invertebrates. The risk is refined on the exposure side, with Step 3 and Step 4 FOCUSsw calculations.

For lettuce, FOCUS Step 4 PECsw values are available both for the annual (once per 12 months) and the biennial (once per 24 months) use. The annual use is proposed at BBCH 41-49, the biennial at BBCH 12-49. Because a higher interception percentage can be taken into account at later crop stages, the PEC values from FOCUS Step 2 are higher for the biennial use. In Step 3 and 4, however, the PEC values are sometimes higher for the annual and sometimes for the biennial use, depending on the scenario. This was not presented clearly in the original DAR, but in this revised version TER values are presented both for the biennial and the annual use.

Refined acute risk assessment for aquatic invertebrates

			0.83	R4 (stream, 1st)	**74.3**	
			2.954	R4 (stream, 2nd)	**20.9**	

For use in hops and both uses in lettuce a safe use is shown at Step 3 for at least one subscenario (TER > 100). Potential mitigation measures are investigated considering Step 4 calculations.

Table 2.6.2-19 Refined TER_A calculations for *C. riparius* based on FOCUS Step 4 for application in hops (90 % drift reduction)

Compound	Species	Endpoint [µg/L]	$PEC_{sw,max}$ [µg/L]	Scenario	TER_A	Trigger
Crop: Hops; 90 % drift reduction (no buffer zone)						
BYI 02960	*C. riparius*	EC_{50} 61.7	0.553	R1, stream	112	100
Crop: Hops; 75 % drift reduction and 10 m buffer zone						
BYI 02960	*C. riparius*	EC_{50} 61.7	0.589	R1, stream	105	100

The above table shows that for hops, acceptable risk can be reached with different combinations of buffer zones and spray drift reduction.

Table 2.6.2-20 Refined TER_A calculations for *C. riparius* based on FOCUS Step 4 for application in lettuce (drift reducing nozzles) – biennial use

Compound	Species	Endpoint [µg/L]	$PEC_{sw,max}$ [µg/L]	Drift reduction [%]	Scenario	TER_A	Trigger
Crop: Lettuce; 50% drift reduction (No buffer)							
BYI 02960	*C. riparius*	EC_{50} 61.7	**0.434**	50	D3 (ditch, 1st)	143	100
			0.446	50	D3 (ditch, 2nd)	139	
			1.033	90	D4 (pond, 1st)	**59.7**	
			0.721	90	D4 (stream, 1st)	**85.6**	
			1.268	90	D6 (ditch, 1st)	**48.7**	

Compound	Species	Endpoint [µg/L]	$PEC_{sw,max}$ [µg/L]	Drift reduction [%]	Scenario	TER_A	Trigger
			0.858	90	R1 (stream, 1st)	**71.9**	
			1.186	90	R1 (stream, 2nd)	**52.0**	
			1.586	90	R2 (stream, 1st)	**38.9**	
			0.940	90	R2 (stream, 2nd)	**65.6**	
			2.226	90	R3 (stream, 1st)	**27.7**	
			3.570	90	R3 (stream, 2nd)	**17.3**	
			4.808	90	R4 (stream, 2nd)	**12.8**	

Table 2.6.2-20 shows that for the biennial use in lettuce, most scenario's do not meet the trigger considering drift reducton only. For the annual use in lettuce, PECsw values are not available considering drift reduction only. Therefore, further refinement is necessary for both lettuce uses. FOCUS Step 4 PECsw values are available based on buffer zones (with drift and/or run-off reduction.

Conclusion acute risk aquatic invertebrates:
A safe use has been shown for the subscenario R1 (pond) in both hops and lettuce with no risk mitigation.

For hops, acceptable risk can be reached in the one relevant complete scenario with different combinations of buffer zones and spray drift reduction.

For the biennial use in lettuce, by applying mitigation measures an acceptable use can be shown for for ten of the fifteen FOCUS subscenarios considering different mitigation options (up to 20m VFS). ~~scenario D3 with no buffer zone and drift reducing nozzles, and for some of the subscenarios R1 stream, R2 stream and R3 stream considering different buffer zones (vegetated filter strips) and drift reducing nozzles~~. Of the seven complete scenario's, three meet the trigger.

For the annual use in lettuce, by applying mitigation measures an acceptable use can be shown for for eight of the fifteen FOCUS subscenarios considering different mitigation options (up to 20m VFS). Of the seven complete scenario's, two meet the trigger.

Refined long-term risk assessment for aquatic invertebrates

			2.827	R1 (stream, 1st)	**2.41**	
			0.139	R1 (pond, 2nd)	49.0	

Compound	Species	Endpoint [µg a.i./L]	$PEC_{sw,max}$ [µg/L]	Scenario	TER_{LT}	Trigger
			2.189	R1 (stream, 2nd)	**3.11**	
			1.215	R2 (stream, 1st)	**5.60**	
			1.044	R2 (stream, 2nd)	**6.52**	
			3.698	R3 (stream, 1st)	**1.84**	
			3.297	R3 (stream, 2nd)	**2.07**	
			0.830	R4 (stream, 1st)	**8.20**	
			2.954	R4 (stream, 2nd)	**2.31**	

The TER_{LT} values for aquatic invertebrates do not meet the required trigger based upon Step 3 PECsw values in one of the two subscenario's in hops, in twelve of the fifteen subscenarios in the biennial use in lettuce and in thirteen of the fifteen subscenarios (all of the seven complete scenarios) in the annual use in lettuce. A refined risk assessment with FOCUS Step 4 values, considering mitigation options is required.

Table 2.6.2-26 TER_{LT} calculations for *C. riparius* based on FOCUS Step 4 for application in hops with exposure mitigation measures

Compound	Species	Endpoint [µg a.i./L]	$PEC_{sw,max}$ [µg/L]	Scenario	TER_{LT}	Trigger
Crop: Hops; no buffer zone 90% drift reduction						
BYI 02960	*C.riparius*	NOEC ~~10~~ 6.81	0.553	R1, stream	~~18.1~~ 12.3	10
5 m distance (spray drift buffer) and 90 % drift reduction						
BYI 02960	*C.riparius*	NOEC ~~10~~ 6.81	0.452	R1, stream	~~22.1~~ 15.1	10
10 m distance (spray drift buffer & VFS*) and 90 % drift reduction						
BYI 02960	*C.riparius*	NOEC ~~10~~ 6.81	0.235	R1, stream	~~42.6~~ 29.0	10
15 m distance (spray drift buffer & VFS*) and 75 % drift reduction						
BYI 02960	*C.riparius*	NOEC ~~10~~ 6.81	0.388	R1, stream	~~25.8~~ 17.6	10

*VFS: vegetated filter strip

The above table shows that for hops, acceptable risk can be reached with different combinations of buffer zones and spray drift reduction.

Table 2.6.2-27 TER_{LT} calculations for *C. riparius* based on FOCUS Step 4 for biannial application in lettuce (drift reducing nozzles)

Compound	Species	Endpoint [µg a.i./L]	$PEC_{sw,max}$ [µg/L]	Drift reduction [%]	Scenario	TER_{LT}	Trigger
Crop: Lettuce; drift reduction (no buffer)							
BYI 02960	*C.riparius*	NOEC ~~10~~ 6.81	0.434	50%	D3 (ditch, 1st)	15.7	10

			4.808	90%	R4 (stream, 2nd)	~~2.08~~ **1.42**	

Table 2.6.2-27shows that for the biennial use in lettuce, most scenario's do not meet the trigger considering drift reducton only. For the annual use in lettuce, PECsw values are not available considering drift reduction only. Therefore, further refinement is necessary for both lettuce uses. FOCUS Step 4 PECsw values are available based on buffer zones, with drift and/or run-off reduction). Since the acute endpoint for C.chironomus is driving the risk assessment, TERLT values are not presented for all possible mitigation measures, but only for the minimum required mitigation that meets the trigger, ór for the strictest mitigation measure in case this does not meet the trigger yet.

Table 2.6.2-28a TER_{LT} calculations for *C.riparius* based on FOCUS Step 4 for biennial application in lettuce (per subscenario, the minimum required mitigation measure is shown to

reach a TER < trigger. If this cannot be reached, the TER is shown at the strictest mitigation measure)

*VFS: vegetated filter strip

Conclusion:

Based on the calculations presented above a safe use of the formulation in hops can be shown for all FOCUS scenarios considering different mitigation options (up to 90% drift reducing nozzles).

Based on the calculations presented above a safe biennial use of the formulation in lettuce can be shown for ten of the ~~thir~~fifteen FOCUS subscenarios considering different mitigation options (up to 20m VFS). Of the seven complete scenario's, three meet the trigger.

A safe annual use of the formulation in lettuce can be shown for nine of the fifteen FOCUS subscenarios considering different mitigation options (up to 20m VFS). Of the seven complete scenario's, three meet the trigger.

Overall conclusion risk aquatic invertebrates:
For hops, acceptable risk can be reached in the one relevant complete scenario with different combinations of buffer zones and spray drift reduction.

For the biennial use in lettuce, an acceptable use can be shown for three of the seven complete FOCUS scenarios considering different mitigation options (up to 20m VFS).

For the annual use in lettuce, an acceptable use can be shown for two of the seven complete FOCUS scenarios considering different mitigation options (up to 20m VFS).

Assessment of bioconcentration potential

BYI 02960 and its relevant metabolites have a log Pow of <3, therefore no study on bioaccumulation is required and there is no concern for bioconcentration.

2.6.3 Effects on bees and other arthropod species

2.6.3.1 Bees

Procedures for risk assessment were in agreement with the recommendations in the Guidance Document on Terrestrial Ecotoxicology Under Council Directive 91/414/EEC (Working Document Sanco/10329/2002 rev 2 final, 17 October 2002, referring to EPPO (EPPO 170 and EPPO 2002). EPPO 2002 was updated with EPPO 2010[11], an update focussing especially on systemic substances.

[11] EPPO 2010: Environmental risk assessment scheme for plant protection products. Chapter 10: Honeybees. OEPP/EPPO, Bulletin OEPP/EPPO Bulletin 40, 323–331

Exposure to honeybees is not relevant for the glasshouse use in lettuce (lettuce for food production needs no pollination therefore honeybees are not expected to be introduced in or be attracted to lettuce production in glasshouse).

Exposure is relevant for the field uses in hops and lettuce. The crops themselves are not attractive to honeybees for nectar and/or pollen collection. However, honey bees may be present in the field to forage on flowering weeds; bees foraging off-field may be exposed via spray drift. Furthermore, potential exposure routes are via honeydew, succeeding crops and guttation and other drinking water sources.

Acute toxicity data and first-tier acute risk assessment

Below the results of laboratory testing with honeybees are summarised.

Table 2.6.3.1-01 Acute toxicity of technical BYI 02960 to honey bees in the laboratory

Test substance	Ecotoxicological Endpoint: LD_{50}		Reference
BYI 02960 (tech.)	oral 24 h oral 48 h contact 24 h contact 48 h contact 72 h contact 96 h	1.3 µg a.i./bee **1.2 µg a.i./bee** >200 µg a.i./bee >200 µg a.i./bee 158.4 µg a.i./bee **122.8 µg a.i./bee**	Schmitzer & Sekine (2008) KIIA 8.7.1/01
	Ecotoxicological Endpoint: NOED		
	oral contact	0.68 µg a.i./bee* 25 µg a.i./bee	

Bold values: Endpoints considered relevant for risk assessment

*The NOED for mortality is 0.68 µg a.i./bee. However, discoordinated movements and aparthy occurred at this and all higher dose rates. The $NOED_{oral}$ for sublethal effects is therefore set at 0.34 µg a.i./bee. The $NOED_{contact}$ is 25 µg a.i./bee also for sublethal effects.

Table 2.6.3.1-02 Acute toxicity data of the formulated product BYI 02960 SL 200 G to honey bees in the laboratory

Test substance	Ecotoxicological Endpoint: LD_{50}		Reference

	Ecotoxicological Endpoint: NOED		
	oral contact	2.6 µg a.i./bee 6.3 µg a.i./bee	

Bold values: Endpoints considered relevant for risk assessment

The acute contact toxicity of the formulaton to bumble bees was also tested, see the table below.

Table 2.6.3.1-03 Acute toxicity of of the formulated product BYI 02960 SL 200 G to bumble bees in the laboratory

Test substance	Ecotoxicological Endpoint: LD_{50}		Reference
Flupyradifurone SL 200 G	contact 48 h	>100 µg a.i./bee	Vergé (2012) KIIA 8.7.1/07
	Ecotoxicological Endpoint: NOED		
	contact	≥100 µg a.i./bee	

In the plant metabolism studies, a range of metabolites have been measured in the reproductive plant organs (flowers). The observed metabolites were tested in acute and chronic toxicity studies for potential effects on honey bees. Table 2.6.3.1-04 provides an overview of the investigated metabolites, including the parent compound. Results of the acute toxicity studies are provided in Table 2.6.3.1-05.

Table 2.6.3.1-04 Overview table on names and synonyms of compounds addressed within the bee chapter

Abbreviation / Chemical code	Alternative name
BYI 02960	Flupyradifurone
BYI 02960-DFEAF	BYI 02960-difluoroethyl-amino-furanone
BYI 02960-OH	BYI 02960-hydroxy
DFA	Difluoroacetic acid
6-CNA	6-chloronicotinic acid
BYI 02960 -CHMP	6-chloropicolyl alcohol, 6-CPA

Table 2.6.3.1-05 Acute toxicity of BYI 02960 metabolites to honey bees in the laboratory

Bold values: Endpoints considered relevant for risk assessment

An indication of hazard (Hazard Quotient or HQ) can be derived according to the EPPO risk assessment scheme, by calculating the ratio between the single application rate (expressed in g/ha) and the lowest laboratory contact and oral LD50 (expressed in µg/bee).

HQ_O and HQ_C resp. = Application rate [g/ha] / LD50 oral or LD50 contact [µg/bee]

HQ values are calculated using data from the studies performed with technical material and the corresponding formulated product. HQ values higher than 50 indicate the need of higher tiered tests to clarify the actual risk to honey bees.

Table 2.6.3.1-06 Hazard quotients for bees – oral exposure

Crop	Exposure route	LD_{50} [µg a.i./bee]	Application rate [g/ha]	Hazard quotient HQ_O	Trigger	Refined risk assessment
BYI 02960 SL 200						
Hops	oral	3.2	150	47	50	No
Lettuce	oral	3.2	125	39	50	No
off-field						
Hops	oral	3.2	150*0.1933	9.1	50	No
Lettuce	oral	3.2	125*0.0277	1.1	50	No
BYI 02960 (technical)						
Hops	oral	1.2	150	**125**	50	**Yes**
Lettuce	oral	1.2	125	**104**	50	**Yes**
off-field						
Hops	oral	1.2	150*0.1933	24	50	No
Lettuce	oral	1.2	125*0.0277	3.5	50	No

The hazard quotients for oral exposure calculated for BYI 02960 technical exceed the empirical trigger value for higher tier testing (HQ_O > 50) for both uses. Therefore, a refined risk assessment will be conducted, see below (higher tier semi-field and field studies).
Because a risk is indicated based on the full in-field dose, the off-field risk is also calculated. The default drift rates of the next section (non-target arthropods other than bees) are used to calculate the

exposure that may occur on the off-field area. Based on these default drift rates and the trigger of 50, an off-field acute risk is not indicated.

Table 2.6.3.1-07 Hazard quotients for bees – contact exposure

Crop	Exposure route	LD_{50} [µg a.i./bee]	Application rate [g/ha]	Hazard quotient HQ_O	Trigger	Refined risk assessment
BYI 02960 SL 200						
Hops	contact	15.7	150	9.6	50	No
Lettuce	contact	15.7	125	8.0	50	No
BYI 02960 (technical)						
Hops	contact	122.8	150	1.22	50	No
Lettuce	contact	122.8	125	1.02	50	No

The hazard quotient for contact exposure is below the empirical trigger value for higher tier testing (HQ_C <50) for both envisaged uses. Therefore, no unacceptable acute risk to bees is to be expected via the contact route of exposure.

Table 2.6.3.1-05 shows that all relevant plant metabolites have a very low acute toxicity to honeybees (all LD50 values >100 µg a.i./bee). Therefore, the acute risk of these metabolites is low.
The bumble bee contact toxicity test does not indicate concern about higher sensitivity of bumble bees than honey bees.

Chronic toxicity data

There are currently no harmonised and ring tested test guidelines available to assess the chronic risk to adult honey bees. Nonetheless, there is some experience within the European honey bee testing community on conducting chronic studies in adult honey bees, by exposing honey bees orally to a treated 50% (w/v) sucrose solution as an exclusive food source for a period of 10 consecutive days by continuous and ad libitum feeding. Since the originally submitted chronic study with the a.s. was deemed unacceptable die to high control mortality and uncertainty about sublethal effects, the notifier performed a new chronic study with the a.s. Table 2.6.3.1-08 provides an overview of the results obtained with parent BYI 02960 and its metabolites.

Table 2.6.3.1-08 Chronic toxicity to adult honey bees in the laboratory

Test substance	Ecotoxicological Endpoint: NOEC / NOED		Reference
BYI 02960	NOEC (nominal) NOED (nominal)	26000 µg a.i./L 0.79 µg a.i./bee/day	Gladbach, Theis et al., 2013 KIIA 8.16.1/09

BYI 02960-DFEAF	NOEC (nominal) NOED (nominal)	≥ 10000 µg a.i./L ≥ 0.435 µg a.i./bee/day	Kling, 2012, KIIA 8.16.1/02
BYI 02960-OH	NOEC (nominal) NOED (nominal)	≥ 10000 µg a.i./L ≥ 0.420 µg a.i./bee/day	Kling, 2012, KIIA 8.16.1/03
DFA	NOEC (nominal) NOED (nominal)	≥ 10000 µg a.i./L ≥ 0.379 µg a.i./bee/day	Kling, 2012, KIIA 8.16.1/04
6-CNA	NOEC (nominal) NOED (nominal)	≥ 10000 µg a.i./L ≥ 0.418 µg a.i./bee/day	Kling, 2012, KIIA 8.16.1/05
BYI 02960-CHMP	NOEC (nominal) NOED (nominal)	≥ 10000 µg a.i./L ≥ 0.413 µg a.i./bee/day	Kling, 2012, KIIA 8.16.1/06

The table shows that all relevant plant metabolites show very low chronic toxicity to honeybees.

The a.s. has chronic mortality endpoints very close to the acute mortality endpoints, see Table 2.6.3.1-09. Thus, the toxicity of the a.s. is not increased when the substance is taken in for several consecutive days; there is no concern about chronic/delayed toxicity with regard to mortality.

Table 2.6.3.1-09 Comparison of acute and chronic endpoints for mortality in adult honey bees

	NOEDoral	$LD(D)_{50}$
Studies with technical grade active substance	[µg a.s./bee(/day)]	[µg a.s./bee(/day)]
Acute adult toxicitv studv (48 hours)	0.68	1.2
Chronic adult toxicitv studv (10 davs)	0.79	1.83

As explained above, the foliage residue toxicity study KIIIA 10.4.3/01 was not evaluated by RMS because guidance on how to perform, evaluate and use this study in the risk assessment is not available in EU.

Chronic toxicity of BYI 02960 to honey bee larvae

There are currently no harmonised and ring tested test guidelines available to assess the chronic risk to honey bee larvae. Nonetheless, there is experience in Europe within some laboratories on

conducting chronic studies in honey bee larvae. A study has been performed with the active substance.

Table 2.6.3.1-10 Chronic toxicity of BYI 02960 honey bee larvae in the laboratory

Test substance	Ecotoxicological Endpoint: NOEC / NOED		Reference
BYI 02960	NOEC (nominal) NOED (nominal)	≥ 10000 µg a.i./kg larval diet ≥ 0.44 µg a.i./bee larvae/day	Nikolakis *et al.*, 2010 KIIIA1 10.4.6.1/01

The chronic toxicity studies with the metabolites show no effects to adult honeybees at the highest tested dose of 10 mg/L diet. The chronic toxicity study with the a.s. shows no effects to honeybee larvae at the highest tested dose of 10 mg/kg diet. Only in the chronic toxicity study on adult honeybees with the a.s., which was performed at higher doses than the other studies, effects were seen. From this study, a NOEC of 26 mg a.i./L/ 0.79 µg a.i./bee/day could be derived. These endpoints could be used in risk calculations based on daily intake values for different castes of honeybees. This is discussed below.

Residue measurements in nectar and pollen and other matrices

Residue measurements in *Phacelia*

An overview of the measured residues of the a.s. and metabolite DFEAF in the semi-field trials on *Phacelia* in the different matrices was compiled by RMS in Tables 2.6.3.1-11-16. In these studies, the first foliar spray applications was done just before flowering and the second foliar spray application was done during full flowering.

Table 2.6.3.1-11 Residues of BYI02960 and metabolite in flowers

Residue measurements in oilseed rape

An overview of the measured residues of the a.s. and metabolite DFEAF in the honey bee field trials on oil seed rape in the different matrices was compiled by RMS in Tables 2.6.3.1-17-24. In these studies, the first foliar spray application was done just before flowering and the second foliar spray application was done during full flowering.

Residue measurements in nectar and pollen of other crops

Four supervised residue trials under semi-field conditions (studies KIIA 8.16.2/04 to /07) were submitted in which the residue levels in melon and tomato flowers, nectar (from combs or honey stomachs) and pollen (from combs or forager honey or bumble bees) were studied. One trial in melon was performed in North-Carolina and studied either a drench or a double foliar application. Two trials in watermelon and one in tomato were performed in Spain and all studied a drench application. The location (for the trial in North Carolina) or the application method (for the drench trials) are less relevant for the GAP under evaluation. Therefore, the residue levels are not summarised in this section nor used in the risk assessment, but all results can be found in Tables 2.6.3.1-16 and -17.

Residue measurements in guttation water

The flupyradifurone residue situation in guttation water was investigated in two field studies in winter oil seed rape (W-OSR) (KIIA 8.16.2/09 and /10, Rexer 2012c and d). The treated seeds in these studies were treated at a rate of nominally 10 g flupyradifurone a.s./kg and were sown at actual rates of 59 and 70 g flupyradifurone a.s./ha. The seeds were sown on field plots which were treated at the day of W-OSR-planting with nominally 300 g flupyradifurone a.s./ha (actually 310 and 311 g flupyradifurone a.s./ha), which was immediately incorporated down to a depth of 15 - 20 cm. Guttation fluid from the W-OSR seedlings were collected from the very first day onwards, at which the first guttation droplets occurred; this started at BBCH 9 - 11, which means at a crop stage with minimal dilution of residues due to plant growth and plant biomass.

The maximum residue level in guttation fluid in the two studies was measured at the very first days where guttation droplets occurred after emergence (actually 12 and 13 days after seed planting); thereafter, the concentrations of flupyradifurone decreased continuously.
In autumn, residues of BYI 02960 above the limit of quantitation (LOQ; 0.010 mg/L) were found in 20 out of 20 analysed samples in autumn 2010 (quantifiable residues ranging from 11 mg/L to 0.039 mg/L in one study and from 21 mg/L to 0.087 mg/L in the other study). Generally, residues of BYI 02960 declined by about two orders of magnitude during the approximately 5 weeks lasting autumn sampling period. In the following spring, residues of BYI 02960 above the LOQ were found in all or the majority of the analysed samples (quantifiable residues ranging from 0.21 mg/L to 0.014 mg/L or 0.15 mg/L to 0.062 mg/L).

In autumn, residues of the metabolite BYI 02960-DFEAF were < LOQ (i.e. < 0.010 mg/L) except for 2 out of 10 or 3 out of 8 analysed samples (collected in the first, (second) and third day of sampling; maximum residue 0.023 mg/L. In spring, all residues of the DFEAF-metabolite were < LOQ.

Residue measurements in soil

Residue measurements in soil were performed in some of the semi-field and field studies, to confirm the artificially incorporated background concentration in soil.

Table 2.6.3.1-25 Residues of BYI02960 in soil

Study	Application rate	DAA1	Residue BYI 02960 (µg/kg) mean (individual samples)	Residue BYI 02960-DFEAF (µg/kg) mean (individual samples)
KIIIA 10.4.7/04	1x 300 (soil appl.) and 2x 200 g a.s./ha (foliar spray)	0	51 (36-51-67)	<1 µg/kg (3 samples)
KIIIA 10.4.7/05	1x 300 (soil appl.) and 2x 200 g a.s./ha (foliar spray)	0	49 (40-56-50)	not done

	spray)			
KIIIA 10.4.5/02	1x 300 g a.s./ha (soil application). 10.1 g a.s./kg OSR seeds (seed treatment), 2x205 g a.s./ha (foliar spray)	0	61 (61)	not done

Risk calculations for exposure via nectar and pollen

The envisaged use of BYI 02960 in hops is an application rate of 150 g a.i./ha, also during the flowering period of the crop. However, hop is a dioecious plant, with male and female flowers developing on separate plants. The harvested commodity in commercial hop cultivation is the female flower cluster. Male hop plants, which could theoretically offer honey bees pollen, are not cultivated in hop plantations – on the contrary: as any pollination of the female flowers (by male pollen) would significantly reduce hop quality, would significantly reduce the harvesting window and would significantly hamper the processing of the hop in breweries, hop plantations are entirely cultivated with female plants. Female flowers, however, do not offer honey bees nectar and pollen. As such, the commercial hop plantations themselves are not attractive to honey bees at any growth stage.

The envisaged use of BYI 02960 in lettuce accounts for an application rate of 125 g a.i./ha, during the development of harvestable, vegetative plant parts. Lettuce does not flower in commercial cultivation (except in seed production, which is not proposed here) and as such, honey bees are not attracted by the crop. Moreover, spray applications of BYI 02960 during flowering are excluded by the envisaged application window.

In conclusion, the crops themselves are not attractive to honeybees for nectar and/or pollen collection. However, weeds may be present in the field and these may flower. In general, the occurrence of weeds and especially flowering weeds in crop fields is not beneficial for growers, a.o. because these weeds will compete with the crop plants for resources. However, weed occurrence will depend on the crop and the individual farmer and may be MS specific. The presence of flowering weeds can therefore not be excluded a priori. For hops especially, undergrowth vegetation is expected to be present. Therefore, the risk via nectar and pollen of flowering weeds should be addressed for the in-field situation.

A large dataset is available with residue measurements.
One semi-field study in Phacelia studied the residue levels after a twofold spray application of 200 g a.s./ha, one just before and one during flowering. Residue levels on pollen and nectar taken from foraging bees directly after the second spray application are high, but decrease quickly:
Phacelia pollen from forager bees one hour after spraying: ca. 65 mg/kg, decreasing within the first day to ca. 36 mg/kg (four hours after spraying). One day after spraying, a level of ca. 10 mg/kg is reached and this decreases within ten days to ca. 0.5 mg/kg.
Phacelia nectar from forager bees one hour after spraying: ca. 3 mg/kg, decreasing within the first day to ca. 1.4 mg/kg (four hours after spraying). One day after spraying, a level of ca. 0.8 mg/kg is reached and this decreases within ten days to ca. 0.04 mg/kg.
The residue levels in pollen and nectar in the hive (maximum ca. 10 mg/kg and 0.1 mg/kg, respectively) are much lower than the residue levels in pollen and nectar collected by forager bees,

but they remain present for a longer time (24 days after spraying, the residue levels in pollen and nectar in the hive are ca. 2 mg/kg and 0.03 mg/kg, respectively). In two other semi-field trials, in which next to two foliar applications, also a soil application was used during sowing, residue levels were only measured on one timepoint but results are more or less in accordance with the results of the study with only foliar applications.

Two field trials in oilseed rape also studied residue levels in pollen and nectar taken from foraging bees. These study included two foliar applications and a seed treatment and furthermore had a background soil concentration.
The highest residue level in oilseed rape pollen from forager bees was found on the day of spraying: 21 mg/kg. The level decreased less rapidly than in the above Phacelia study (without seed treatment), reaching a level of ca. 1-2 mg/kg within ten days.
The highest residue level in oilseed rape nectar from forager bees was found three days after spraying: ca. 4 mg/kg. The level decreased to ca. 2 mg/kg within ten days.
The residue levels in pollen and nectar in the hive (maximum values of individual samples ca. 4 mg/kg and 1 mg/kg, respectively) are lower than the residue levels in pollen and nectar collected by forager bees. Hive residues were only measured on day 10 or day 23 after the last application and not earlier, so a direct comparison is difficult. Hive residues remain present for a longer time (23 days after spraying, the residue levels in pollen and nectar in the hive are maximum 1 mg/kg and 0.6 mg/kg, respectively; after 180 days, still 0.004 mg/kg is found in beebread).

In all the above studies, residue levels of metabolite DFEAF are much lower than those of the a.s. and decrease in a similar way.

It is difficult to determine a generic RUD value from these residue measurements, as the trials were performed with different application regimes and each trial had multiple applications. However, a general picture can be derived: directly after spraying, high levels of the a.s. can be found in nectar and pollen; residues in pollen are higher than those in nectar; residue levels in pollen and nectar in the hive seem to be lower than the residue levels in pollen and nectar collected by forager bees, but they remain present for a longer time; after six months, still traces of the a.s. can be found in the beebread; the residue levels of metabolite DFEAF are much lower than those of the a.s.

These residue levels could be used in exposure calculations, using daily intake values for nectar and pollen for different castes of bees. The exposure values could then be compared to the toxicity values derived above. If such an exercise is undertaken, it should be noted that the residue levels were determined in studies which used at least two foliar sprays with 200 g a.s./ha each, while the proposed uses in hops and lettuce have only a single application, at 150 and 125 g a.s./ha, respectively, and furthermore are not attractive to bees themselves. However, at the moment there is no harmonised

method available to calculate these exposure levels and especially the corresponding risk. Furthermore, it is not necessary to perform these lower tier calculations, as a large number of higher tier effect studies is available. Please see the section below (higher tier toxicity data and risk assessment).

Higher tier toxicity data and risk assessment for exposure via nectar and pollen

Six independent semi-field (gauze tunnel) studies were submitted, where BYI 02960 formulations were applied to the highly bee attractive surrogate crop Phacelia tanacetifolia with honey bees actively foraging on the crop (i.e. during bee flight). The studies are summarised in Table 2.6.3.1-26. One of these studies was not accepted (except for residue analysis) because of an unequal colony set-up.

The studies were all performed by two different laboratories. Differences between these laboratories were reflected in the report for the use of statistics and preparation of tables or figures. RMS has prepared stacked figures in those cases that figures were missing. In that way the interpretation of the results was more convenient as comparisons between studies are made easier and more transparent.

According to the notifier, " the results of all of the six semi-field (tunnel) studies under forced and as such worst-case exposure conditions consistently did not show any adverse effects on mortality, foraging activity, behaviour, brood-, food- and population development or on overall colony vitality". They state that "overall, the laboratory database shows that BYI 02960 does not exhibit delayed or chronic effects, either in adult bees or in honey bee larvae. BYI 02960 metabolites are virtually non-toxic to honey bees and there is no indication that BYI 02960 metabolites are of any higher toxicity regarding potentially delayed or chronic effects than the parent compound. These laboratory findings

have been consistently confirmed by in total six independent semi-field tunnel studies in the highly bee attractive surrogate crop Phacelia tanacetifolia. As such, it can be concluded that BYI 02960 can be applied at foliar application rates of up to and including 200 g a.i./ha, even to bee-attractive, full-flowering crops during honey bees actively foraging, without adverse effects on honey bees, honey bee brood and honey bee colonies."

RMS however notes the following:

- Study 01 and /02 were not performed under GLP and are therefore less reliable. However, they represent the two lowest exposure situations in the dataset and are therefore less important for the overall conclusion.

- Endpoints in this type of semi-field study are interrelated. For instance mortality of bees outside the hive will depend on flight intensity. When flight intensity is reduced, mortality in the tunnel might be reduced as well as fewer bees are foraging. This was indeed the case in the studies where reduction of flight intensity was observed. Flight intensity was significantly reduced in studies 10.4.7/03-06; reduction was observed for three to seven days.

- Significant effects on flight intensity are present in studies 10.4.6/3 to 10.4.7/6. In studies 10.4.6/1 and /2 however, flight intensity was not evaluated statistically. Differences between studies may therefore be biased by the performing laboratory. However, based on visual inspection of the data RMS agrees that studies 10.4.6/1 and/2 do not suggest an effect on foraging activity.

- Repellence of flupyradifurone leads to decreased flight intensity. In that way bees will minimize exposure of the hive to flupyradifurone. In the studies in which reduced flight intensity was seen, effects on other endpoints were not clearly visible.

- Of course, a short-term reduction of flight intensity can be an effective way to reduce exposure and possibly related risk for honey bee colonies. It can only be seen as an acceptable effect if it does not lead to effects on bee colonies in the longer term from a shortage of food. This was not apparent in the semi-field studies (brood development, food storage area and colony strength comparable to control in all studies) but effects on these parameters can potentially be masked by the small colony size and confined conditions..

- Exposure in the tunnel was on average 12 days. Longer exposure is not feasible as the foraging opportunities within a tunnel are too limited. It was evident in most studies that there was a reduction of the colony strength during confinement in the tunnel. After placement of the hives in the open field, colonies started to grow again. Any effects of the active substance can therefore be masked by the stronger effect of confinement to the tunnel. Moreover, due to

natural variability between the hives it is extremely difficult to evaluate differences between treatment and control.

- Reduction of flight intensity and effects on behaviour were observed in those studies that were worst case for number of applications and timing of the applications (those ranked by RMS as 1, 2, 3 and 4).

- So far guidance has not been developed for the interpretation of changes of endpoints on brood development. Since the endpoints are interrelated, possible effects are difficult to disentangle. Evaluation of these endpoints is difficult without a clear perspective on normal brood development.

- It is not yet clear if and how results can be assessed statistically. Indeed, in these 6 studies, statistical assessment has not been performed on endpoints of brood development.

- Confined conditions may result in possible stress on bees which may result in a natural reduction of brood activity when bees are kept inside tunnels for longer periods. In these studies reductions of brood activity are indeed often observed during confinement to the tunnels.

- According to the EFSA opinion on bees, it is not possible to assess pollen and nectar storage and hive weight development due to the small size of the colony; therefore, it is difficult to assess potential effects on honey production (i.e. a potential protection goal) when adverse effects are observed on other parameters. As smaller sizes of colonies are used in semi-field studies, the interpretation of impacts on full size colonies will be difficult and the possibility to translate adverse effects on a small colony to a full size colony seems limited. Due to confined conditions, the small size of the colony and the high turnover rate of nectar and pollen in the tunnels, it is not possible to assess hive weight development and direct potential effects on honey production.

Based on the above, the semi-field studies alone are not considered sufficient proof that the risk to bees is acceptable. However, also two field studies and one long-term colony feeding study were submitted. These are summarised in Table 2.6.3.1-27.

Table 2.6.3.1-27 Overview of field and long-term feeding studies

Number of bees	Similar to control	Similar to control	Similar to control
Weight of colony	Similar to control	Similar to control	Similar to control
Development of brood	Similar to control	Similar to control	Similar to control
Development of food storage aria	Increase pollen and nectar stores similar to control	Increase pollen and nectar stores similar to control	Increase pollen and nectar stores similar to control
Behaviour	intensive cleaning behaviour and locomotion problems in small fraction of bees of treated colonies on day after 2nd foliar application	no treatment-related effects	
Remark			The low number of replicates (especially in the control, with only three remaining replicates) and the apparent variation within the treatment groups in mortality of bees/drones/immature stages make it difficult to draw conclusions on the effect of the treatment. What can be concluded is that, under the specific circumstances of this study, the different treatments of the test substance do not lead to an adverse effect in one of the observed parameters (or the combination of adverse effects of the different parameters) to such an extent, that it led to the collapse of one or more colonies.
Statistics for mortality and flight intensity	no	no	yes
Statistics for brood and food storage	no	no	yes

Thus, these studies confirm the results of the semi-field studies.

In the two field studies on oil seed rape, no adverse effects on honey bees were seen during the exposure period nor during the observation period which included overwintering. The only treatment-related effects were a short-term (two days) reduction on flight intensity in both studies and some behavioural anomalies in a small fraction of bees for one day in one of the two studies. These effects

apparently did not lead to direct or delayed effects on survival or wellbeing of the colonies as compared to the control colonies. Exposure in the field studies was confirmed with residue measurements in nectar and pollen both from forager bees and from hive matrices.

Also, a long-term feeding study was submitted in which colonies were forced to feed on up to 10 mg/kg diet for seven weeks. This is clearly a worst-case exposure for the GAPs of the semi-field and field studies (2x 200 g a.s./ha foliar spray and in some cases also background soil concentration included). In these trials, the initial concentration in pollen and nectar taken from forager bees could be above 10 mg/kg on the first days, but this quickly decreased to below 10 mg/kg. In the hives, the concentration in pollen or nectar never exceeded a maximum value of 10 mg/kg and also decreased to much below that level soon. This study had some shortcomings but it can be concluded that a 7-week exposure to 10mg flupyradifurone/kg diet does not lead to collapse of a colony, including overwintering.

The overall data package shows that the spraying of 2x 200 g a.s./ha on a bee-attractive crop during full flowering and active foraging of honey bees does not result in adverse acute or long-term (including overwintering) effects on honey bee colonies.

This data package covers the proposed uses in the non-attractive crops lettuce and hops with application rates of 1x125 and 1x150 g a.s./ha, respectively. For these crops, the main concern is via flowering weeds especially in the hop plantations. The above studies in highly attractive crops indicate that a low risk is expected from these uses via nectar and pollen of flowering weeds.

Expert discussion in Pesticide Peer Review meeting 124 (December 2014):

The RMS concluded that the data sets indicate that overall no adverse acute or long-term effects (including over-wintering evaluation) were indicated for a spray of 2 x 200 g a.s./ha on bee attractive crops during full flowering and active foraging (1 application prior to flowering and 1 application during flowering). The experts at the meeting agreed with the conclusion of the RMS noting that some slight transient treatment related effects may have been observed.

Risk assessment for other exposure routes

Exposure via honeydew

Aphids are expected to be more sensitive to flupyradifurone than bees because they are target pest species. If they are indeed more sensitive, buildup of honeydew at a level that can harm honeybees is not expected. However, this needs to be confirmed with data. The notifier has submitted dose-response studies with aphids (KIIIA1 6.1.1) . However, actual LD50 values were not found in the dose-

response studies and the doses are expressed in g a.s./ha; therefore they are not useful for a comparison with the toxicity to honeybees. The notifier also submitted an LD50-study with the green peach aphid. The raw data of the LD50-study with the green peach aphid need to be submitted before conclusions can be drawn about the usefulness of the study. However, based on the conclusion above that the risk via direct overspray and via nectar and pollen of highly attractive flowering crops is acceptable, a high risk via honeydew (directly oversprayed or produced (much) later by aphids) is not expected either.

Expert discussion in Pesticide Peer Review meeting 124 (December 2014):

The RMS included a consideration of the risk via insect honey dew in the DAR. The RMS considers that the higher tier studies were sufficient to cover the risk to honey bees via this route of exposure. The experts agreed with the conclusions of the RMS that this route of exposure was addressed.

Risk assessment for other exposure routes

Exposure via honeydew

Aphids are expected to be more sensitive to flupyradifurone than bees because they are target pest species. If they are indeed more sensitive, buildup of honeydew at a level that can harm honeybees is not expected. However, this needs to be confirmed with data. The notifier has submitted dose-response studies with aphids (KIIIA1 6.1.1) . However, actual LD50 values were not found in the dose-response studies and the doses are expressed in g a.s./ha; therefore they are not useful for a comparison with the toxicity to honeybees. The notifier also submitted an LD50-study with the green peach aphid. The raw data of the LD50-study with the green peach aphid need to be submitted before conclusions can be drawn about the usefulness of the study. However, based on the conclusion above that the risk via direct overspray and via nectar and pollen of highly attractive flowering crops is acceptable, a high risk via honeydew (directly oversprayed or produced (much) later by aphids) is not expected either.

Exposure via guttation and other water sources

The relevance of exposure via guttation droplets and other water sources for honey bee risk assessment is not yet clear. The risk via guttation droplets is generally estimated to be highest from droplets on young seedlings grown from treated seeds. The applicant submitted two studies in which the residue level in young oil seed rape seedlings, sown in soil with a background concentration covering the PECplateau of the proposed uses, was measured. A highest level of 21 mg/L was found (initial level, quickly declining). This is comparable to the NOEC-value from the chronic honey bee laboratory study with technical flupyradifurone (10-d feeding of 26 mg/kg in highly bee attractive sugar solution). Therefore, a high risk via guttation is not indicated. Based on the conclusion above (see section higher tier toxicity data and risk assessment) that the risk via direct overspray and via nectar

and pollen of highly attractive flowering crops is acceptable, a high risk via other water sources (e.g. puddles, surface water) is not expected either.

Exposure via succeeding crops

In order to account for potential side-effects on honey bees from a potential carry-over of soil-borne flupyradifurone residues into potentially bee-attractive, succeeding flowering cops, a worst-case soil-plateau concentration was established in two out of four semi-field studies in Phacelia tanacetifolia as well as in both long term honey bee health field studies in W-OSR. In all of these four studies which evaluated potential side-effects on honey bees, nominally 300 g flupyradifurone a.s./ha was applied onto the soil at the day of crop planting, to be immediately incorporated down to depth of 20 cm to establish a worst-case, non-aged flupyradifurone soil plateau concentration within the root zone of the planted, bee-attractive flowering crop. The analytically determined soil concentration in these four studies was in the range of 36 - 76 µg flupyradifurone a.s./kg soil.

These analytically determined soil concentrations can be compared to the soil plateau concentration that has been calculated in the fate section. The PECplateau for lettuce of 0.016 mg/kg (over 20 cm) is clearly covered. For hops, the reported PECplateau is 0.080 mg/kg, but this is calculated over 5 cm for perennial crops without tillage. In case of succeeding crops other than hops, tillage will take place and it can be assumed that the soil concentration will be spread over 20 cm, leading to a soil concentration of 0.020 mg/kg. Thus, risk via succeeding crops of the use in hops is also covered with the effect semi-field and field studies.

2.6.3.2 Other arthropod species

Procedures for risk assessment were in agreement with the recommendations in the Guidance Document on Terrestrial Ecotoxicology Under Council Directive 91/414/EEC (Working Document Sanco/10329/2002 rev 2 final, 17 October 2002, referring to ESCORT 2). The recommendations of ESCORT 3, a follow-up workshop, are taken into account for this DAR for issues where guidance is lacking.

In glasshouse crops for which Integrated Pest Management systems are used, introduced natural enemies may be exposed to flupyradifurone and, considering the results of in-field risk calculations for the field uses (see below), significantly affected This issue is not assessed in the framework of the DAR but can be taken account at Member State level.

Toxicity tests on non-target arthropods have been performed with BYI 02960 SL 200 G on the species *Typhlodromus pyri*, *Aphidius rhopalosiphi*, *Coccinella septempunctata*, *Aleochara bilineata* and *Orius*

laevigatus. Furthermore, two full-fauna off-crop field studies were conducted. Table 2.6.3.2-01 below summarises the results of laboratory testing with non-target arthropod species.

Table 2.6.3.2- 01 Ecotoxicological endpoints for arthropods other than bees (BYI 02960 SL 200)

A: A negative value indicates a lower mortality in the treatment than in the control.
B: A negative value indicates a higher reproduction rate in the treatment than in the control.
C: A negative value indicates a higher percentage of wasps found on plants in the treatment than in the control.

D: A negative value indicates a higher nymphal hatching rate in the treatment than in the control.
n.a.: Not assessed.
sign.: statistically significant at 5%-level (only indicated for repellency).
n.sign.: not statistically significant (only indicated for repellency).

The tier 1 glass plate studies indicate that insects, as represented by *Aphidius rhopalosiphi* (LR50 < 0.5 g a.i./ha), are more sensitive to the exposure of BYI 02960 SL 200 G than mites like *Typhlodromus pyri* (LR50 17.3 g a.i./ha). This has been confirmed by extended laboratory studies for the same two species. A comparison of the extended laboratory results for *Aphidius rhopalosiphi* (LR50 2.02 g a.i./ha, ER50 >0.89 and <1.58 g a.i./ha) with the results from the additionally tested species *Coccinella septempunctata* (LR50 273.9 g a.i./ha and no effects on reproduction below the LR50) and *Aleochara bilineata* (ER50 >300 g a.i./ha) gives clear evidence, that *Aphidius rhopalosiphi* is by far the most sensitive species.
Hence, aged residue studies were conducted with *Aphidius rhopalosiphi* and - in addition - with the predatory bug *Orius laevigatus*. The results showed that *Orius laevigatus* is also susceptible to the exposure of BYI 02960 SL 200 G (effects <50% after 28 days of aging) but clearly less sensitive than *Aphidius rhopalosiphi* (effects <50% after 49 days of aging). For this reason, the risk assessment of *Orius laevigatus* is considered to be covered by the risk assessment for *Aphidius rhopalosiphi*.

Data have been submitted on *Typhlodromus pyri* and *Aphidius rhopalosiphi* (i.e. two indicator species) as well as three crop-relevant species (*Coccinella septempunctata, Aleochara bilineata* and *Orius laevigatus*). From these studies a risk assessment is performed according to the recommendations of ESCORT 2.

Tier 1 risk assessment

In the 1st tier, the LR50 values of laboratory glassplate tests with the two indicator species are taken into account. The hazard quotient (HQ) is calculated as follows:

In field-HQ = max. single application rate * MAF / LR_{50}
Off-field HQ = max. single application rate * MAF * (drift factor/VDF)*correction factor / LR_{50}

- Max. single application rate = 125 g a.i./ha (lettuce), 150 g a.i./ha (hops)
- MAF (multiple application factor) = 1 (only 1 application)
- Drift factor = 19.33% (hop, 3 m distance, 1 application; ESCORT2) 2.77% (lettuce (field crops), 1m distance, 1 application; ESCORT2)

- VDF (vegetation distribution factor) = 10 (default value as recommended by the Terrestrial Guidance Document, to take into account the 3-dimensional structure of the off-field vegetation)
- Correction factor = 10 (uncertainty factor for the extrapolation from indicator species to all off-field non-target arthropods; default value for tier 1 risk assessment according to the Terrestrial Guidance Document)

The risk is considered acceptable if the calculated HQ is < 2. See the Tables below.

Table 2.6.3.2-02 HQ for terrestrial non-target arthropods for the in-field scenario

Crop (field uses)	Species	Appl. rate [g a.i./ha]	MAF	LR_{50} [g a.i./ha]	HQ	Trigger
Hops	*A. rhopalosiphi*	150	1	<0.5	**>300**	2
Hops	*T. pyri*	150	1	17	**8.8**	2
Lettuce	*A. rhopalosiphi*	125	1	<0.5	**>250**	2
Lettuce	*T. pyri*	125	1	17	**7.4**	2

Conclusion: For both standard species, the in-field HQ values are above the trigger of concern, indicating a need for refinement.

Table 2.6.3.2-03 HQ for terrestrial non-target arthropods for the off-field scenario

Crop	Species	Appl. rate [g a.i./ha]	MAF	Drift [%]	VDF	Corr. factor	LR_{50} [g a.i./ha]	HQ	Trigger
Hops	*A. rhopalosiphi*	150	1	19.33	10	10	<0.5	**>58**	2
Hops	*T. pyri*	150	1	19.33	10	10	17	1.7	2
Lettuce	*A. rhopalosiphi*	125	1	2.77	10	10	<0.5	**>6.9**	2
Lettuce	*T. pyri*	125	1	2.77	10	10	17	0.2	2

Conclusion: The HQ values for *Typhlodromus pyri* are below the trigger of concern for both uses. However, both HQ values for *Aphidius* are above the trigger of 2, indicating a need for refinement.

<u>Tier 2 risk assessment</u>

In the 2nd tier, the results of extended laboratory tests are taken into account (LR50, ER50 and/or effect percentages). These are available for four species.

The exposure is calculated as:

In-field: Application rate * MAF
In-field (high crops) Application rate * MAF * 0.5
Off-field: Application rate * MAF * (drift factor / VDF) *correction factor

- Max. single application rate = 125 g a.i./ha (lettuce), 150 g a.i./ha (hops)
- MAF (multiple application factor) = 1 (only 1 application)

- Factor 0.5 for high crops: The correction factor of 0.5 for the in-field exposure assessment in three-dimensional crops according to ESCORT2 (see footnote "a" in legend on page 19 of the ESCORT2 document) can be applied according to the notifier. However, application in hops can start from a stage in which the plants are still small, BBCH 31. The BBCH scale describes the hop plants between BBCH 31 and 38 as follows:

  Principal growth stage 3: Elongation of bines
  31 Bines have reached 10% of top wire height
  32 Bines have reached 20% of top wire height
  33 Bines have reached 30% of top wire height
  3 . Stages continuous till . . .
  38 Plants have reached the top wire

  At the beginning of the application period (BBCH 31-37), the plants are still thin and small (ca. 40cm based on a top wire size of 4m) and it is not justified to use the factor of 0.5. Furthermore, it is unclear whether the correction factor can really also be used for hops. Since no justification/validation for the use of the factor of 0.5 for other crops than orchards and vineyards, the crops mentioned in ESCORT 2, is available, the risk is calculated without correction factor.
- Drift factor = 19.33% (hop, 3 m distance, 1 application; ESCORT2; considered relevant for all grwoth stages since the same application machinery will be used throughout the season); 2.77% (lettuce (field crops), 1m distance, 1 application; ESCORT2)
- VDF (vegetation distribution factor) = 10 (default value as recommended by the Terrestrial Guidance Document, to take into account the 3-dimensional structure of the off-field vegetation; it can only be applied in the context of 2D test systems)
- Correction factor = 5 (uncertainty factor for the extrapolation from indicator species to all off-field non-target arthropods; default value for tier 2 risk assessment)

Table 2.6.3.2-04 Exposure calculation for in-field assessment

Crop / no. of applications	Appl. rate [g a.i./ha]	MAF	factor to account for high crops	in-field PEC_{max}. [g/ha]
Hops BBCH 31-38 / 1	150	1	n.a.	150
Lettuce / 1	125	1	n.a.	125

Table 2.6.3.2-05 Exposure calculation for off-field risk assessment

Appl. rate [g a.i./ha]	MAF	Drift [%]	Veg. distr. factor	Correction factor	off-field $PEC_{max.}$ [g/ha]	Remark
150	1	19.33	-	5	145	in case of 3-D study design
150	1	19.33	10	5	14.5	in case of 2-D study design
125	1	2.77	-	5	17.3	in case of 3-D study design
125	1	2.77	10	5	1.73	in case of 2-D study design

Tier 2 in-field risk assessment

The in-field exposure PEC values are compared to the results of the extended laboratory studies.

Table 2.6.3.2-06 In-field risk assessment based on study results from extended laboratory studies

Test Species	in-field $PEC_{max.}$, [g a.i./ha]	LR_{50}/ ER_{50} [g a.i./ha]	Trigger	Refined assessment

				required?
Use in hops, 1 x 150 g a.i./ha				
Typhlodromus pyri	150	177 / >142	Effects are < 50%	no*
Aphidius rhopalosiphi	150	2.02 / >0.89	Effects are < 50%	**yes**
Coccinella septempunctata	150	273.9 / no effects up to 250	Effects are < 50%	no
Aleochara bilineata	150	>300	Effects are < 50%	no
Use in lettuce, 1 x 125 g a.i./ha				
Typhlodromus pyri	125	177 / >142	Effects are < 50%	no
Aphidius rhopalosiphi	125	2.02 / >0.89	Effects are < 50%	**yes**
Coccinella septempunctata	125	273.9 / no effects up to 250	Effects are < 50%	no
Aleochara bilineata	125	>300	Effects are < 50%	no

* No adverse effects on reproduction were seen up to 142 g a.s./ha. The LR50 is 177 g a.s./ha. It is likely that at 150 g a.s./ha no adverse effects on *Typhlodromus* will occur.

The higher tier in-field risk assessment for *Typhlodromus, Coccinella* and *Aleochara* indicates that no unacceptable adverse effects are to be expected in the in-field area for arthropod species with a similar sensitivity as these species. However, the in-field risk assessment for *Aphidius rhopalosiphi* indicates that initial effects in the in-field area cannot be excluded. Therefore, further refinement is needed.

Refined in-field risk assessment

The results of the tier 2 risk assessment indicate that initial effects on species with a similar sensitivity as *Aphidius rhopalosiphi* cannot be excluded. As a consequence, an aged residue study was performed to demonstrate the potential for recovery for *Aphidius rhopalosiphi*, the most sensitive tested species, and in addition for the predatory bug *Orius laevigatus*.

An extended laboratory aged residue study has been performed on *Aphidius rhopalosiphi* (Jans, 2010; KIIIA1 10.5.3/01). In this study, BYI 02960 SL 200 was applied 2 times at a rate of 250 g a.i./ha with a 10 days interval on potted maize plants. Spray residues were aged under semi-field conditions. Bioassays with freshly dried residues, residues aged for 14 days and for 28 days, respectively, resulted in a corrected morality of 100, 90 and 76.7%, respectively. After an ageing time of 42, 49 and 56 days, corrected mortalities of 29.6, 20.0 and 6.7% were recorded, respectively. Exposure to residues aged for 42 days resulted in a 89.9% reduction in reproduction relative to the control. No effects on reproduction >50% were observed after an ageing time of 49 and 56 days, respectively. Statistically significant repellency was recorded in the first, second and third bioassay (aged 0, 14 and

28 days), while in the fourth, fifth and sixth bioassay (aged 42, 49 and 56 days) no repellent effects were observed.

A second extended laboratory aged residue study has been performed on *Orius laevigatus* (Schwarz, 2010; KIIIA1 10.5.3/02). BYI 02960 SL 200 was applied 2 times at a rate of 250 g a.i./ha with an application interval of 10 days onto potted apple plants. *Orius laevigatus* showed a corrected mortality of 100 and 75.6%, when exposed to fresh residues of the test item and residues aged for 14 days, respectively. After an ageing time of 28 and 42 days, a corrected mortality of 24.5 and 9.8% was observed, respectively. No adverse effects on reproduction > 50% were observed after an ageing time of 28 and 42 days, respectively. The results indicated that *Orius laevigatus* is as well susceptible to the exposure of BYI 02960 SL 200 G (effects <50% after 28 days of ageing) but clearly less sensitive as *Aphidius rhopalosiphi* (effects <50% after 49 days of ageing).

These aged residue studies indicate that the potential for recovery is given even after 2 applications at a rate of 250 g a.i./ha within 7 weeks for the most sensitive species, *Aphidius rhopalosiphi*. For *Orius laevigatus*, residues aged for only 4 weeks already had no adverse effect on mortality and reproduction. Since the intended use pattern includes only single applications at a rate of up to 150 g a.i./ha in the field it can be concluded that the potential for recovery is given within a few weeks after the application and no unacceptable in-field risk for non-target arthropods has to be expected from the use of BYI 02960 SL 200 according to the proposed use pattern.
It is noted that the ageing in the studies was done under semi-field conditions and on plants which could potentially cause more growth dilution than other plant species, and therefore the aged residue studies do not represent all possible field conditions. Thus, a generic ‘potential for recovery’ period cannot be quantified. However, RMS considers that a potential for recovery within one year (the required period for in-field risk assessment according to ESCORT 2) has been shown.

Tier 2 off-field risk assessment
The off-field exposure PEC values are compared to the results of the extended laboratory studies.

Table 2.6.3.2-07 Off-field risk assessment based on study results from extended laboratory studies

Test Species	off-field $PEC_{max.}$, [g a.i./ha]	LR_{50}/ ER_{50} [g a.i./ha]	Trigger	Refined assessment required?
Use in hops, 1 x 150 g a.i./ha				
Typhlodromus pyri	14.5	177 / >142	Effects are < 50%	no
Aphidius rhopalosiphi	145	2.02 / >0.89	Effects are < 50%	**yes**
Coccinella septempunctata	14.5	273.9 / no	Effects are <	no

		effects up to 250	50%	
Aleochara bilineata	14.5	>300	Effects are < 50%	no
Use in lettuce, 1 x 125 g a.i./ha				
Typhlodromus pyri	1.73	177 / >142	Effects are < 50%	no
Aphidius rhopalosiphi	17.3	2.02 / >0.89	Effects are < 50%	**yes**
Coccinella septempunctata	1.73	273.9 / no effects up to 250	Effects are < 50%	no
Aleochara bilineata	1.73	>300	Effects are < 50%	no

The maximum PEC off-field for the use in hop (worst-case) is calculated to be 14.5 g/ha for 2D-test systems and 144.9 g/ha for 3D-test systems. For *Typhlodromus*, *Coccinella* and *Aleochara* no effects > 50% neither on mortality nor on reproduction were observed in extended laboratory studies on natural substrate at a rate of 142 (*Typhlodromus*), 250 (*Coccinella*, 2nd trial) and 300 g a.i./ha (*Aleochara*), respectively (see Table 2.6.3.2-07). However, for *Aphidius*, initial effects cannot be excluded, indicating a need for further refinement.

Refined off-field risk assessment

To assess off-field effects of BYI 02960 SL 200 on naturally occurring arthropod communities under more realistic conditions, two full-fauna field studies were conducted on grassland as surrogate for off-field habitats in the Netherlands and in Southwestern France.

BYI 02960 SL 200 was applied in a dose-response design at drift rates (0.51, 1.7, 5.1 and 21 g a.i./ha) to grassland habitats with little agricultural input in the Netherlands and Southwestern France. These sites held a diverse and representative off-crop non-target arthropod community. Four replicate plots of 24 x 24 m or 22 x 22 m each were used per treatment (4 application rates, control, reference treatment = 24 plots in total). Arthropods were sampled comprehensively using three different sampling methods (pitfall, suction and weed/Berlese sampling) shortly before the application and 1, 2, 4 and 8 weeks after the application. Overall community changes relative to the control were analyzed using multivariate statistics and depicted by Principal Response Curves (PRC).
In addition, effects on individual arthropod populations were analyzed with univariate statistics for taxa that were sufficiently abundant. In both studies, the toxic reference item treatment caused clear responses both at the arthropod community level and at the population level, demonstrating that the test system was sufficiently sensitive to detect toxic effects.
Both field tests contained sufficient numbers for analysis of effects on the Hymenopteran family Braconidae, to which the most sensitive first tier species *Aphidius rhopalosiphi* belongs.

<u>Results of the trial in the Netherlands:</u>

At community level, no statistically significant effects on arthropod communities were found at any of the rates tested up to and including 21 g a.i./ha. Therefore, 21 g a.i./ha is the community NOER (No Observed Effect Rate) of BYI 02960 SL 200. In addition, 72 taxa were sufficiently abundant for a univariate statistical evaluation at population level. In the three lowest test rates, none of the taxa showed a consistent treatment-related response. Predatory mites of the family *Cunaxidae* and hymenopteran parasitoids of the family *Braconidae* showed transient adverse effects only at one sampling moment shortly after application of the highest test rate (21 g a.i./ha). Both taxa recovered within one week. In conclusion, the population NOEAER (No Observed Ecologically Adverse Effect Rate) of BYI 02960 SL 200 is 21 g a.i./ha and the population NOER (No Observed Effect Rate) is 5.1 g a.i./ha.

Results of the trial in France:

At community level, no statistically significant effects on arthropod communities were found at any of the rates tested up to and including 21 g a.i./ha. Therefore, 21 g a.i./ha is the community NOER (No Observed Effect Rate) of BYI 02960 SL 200.

At the population level, 79 taxa were sufficiently abundant for population level evaluations. Only three phytophagous taxa were adversely affected.

At the test rate of 5.1 g a.i./ha, significant adverse effects on the chrysomelid beetles *Alticinae* and on juvenile leafhoppers (*Cicadellidae*) occurred at a single sampling occasion. At the rate of 21 g a.i./ha, *Alticinae* and *Cicadellidae* showed statistically significant reductions at two sampling moments after application, but recovered already 4 weeks after the application. Aphids (*Aphidoidea*) were reduced at several sampling moments after the application of 21 g a.i./ha; however, the reduction was only statistically significant at the penultimate sampling moment. The observed effects on *Aphidoidea* were to be expected since aphids are a target pest species for the proposed uses of BYI 02960 SL 200 in lettuce and hop. However, aphids can be expected to recover quickly from population declines due to their high asexual reproductive potential. No significant reduction in *Aphidoidea* abundance was observed at the last sampling moment two months after application of the test item. The highest rate tested in this study - BYI 02960 SL 200 applied at 21 g a.i./ha - is therefore classified as the population NOEAER (No Observed Ecologically Adverse Effect Rate) with effect class 3a; the second highest dose rate – 5.1 g a.i./ha is the NOEAER with effect class 2.

In the Terrestrial ecotoxicology guidance document and in ESCORT 2, there is no clear guidance on what endpoints should be used from field studies for risk assessment. The report from the ESCORT 3 workshop contains some relevant recommendations: (chapter 1.8.1.2, p.9) ‘ Class 3 effects may be appropiate for the off-crop in-field margin, and Class 1 and 2 are appropiate for off-field area’; (chapter 5.3, p.40) ‘ Considering field studies for off-crop risk assessment, no effect or only transient effects (e.g. de Jong et al. 2010) are considered acceptable’; and (chapter 7.1, p.49): ‘At the level of field

studies, the NOER community and the NOEAER population should be used for the off-field risk assessment.'.

The drift values used to calculate the off-field exposure were determined at distances from the *crop*. In the current risk assessment, differentiation between ' off-crop in-field' and ' off-field' is not done. Depending on MS, crop type, farmer, etc., there may or may not be an in-field off-crop buffer zone. To ensure that the off-field is adequately protected, in this risk assessment the situation without off-crop in-field zone is assumed.

In both field studies, the community NOER is 21 g a.s./ha.
As NOEAER, three values were set:

Study in NL: 21 g a.s./ha is the population level NOEAER with effect class 2

Study in SW-FR: 5.1 g a.s./ha is the population level NOEAER with effect class 2; 21 g a.s./ha is the population level NOEAER with effect class 3a

Based on the recommendations of ESCORT 3, the community NOER and the community NOEAER values with effect class 2 are considered and the lowest of these is taken. Thus, the relevant endpoint for the risk assessment would be 5.1 g a.s./ha based on the population NOEAER effect class 2 from the study in France. Because two field studies are available, the RMS does not consider an additional safety factor on this value necessary.

The relevant endpoint for the risk assessment from these studies was discussed in Pesticide Peer Review meeting 124 of December 2014. The studies had a checkerboard design, meaning that there were areas of low dose and control which could serve as source of recolonisation for the populations. The experts questioned whether there was more possibility for recolonisation in these studies than there would be in a normal agricultural off-field situation. It was therefore decided in the meeting that the NOER values could be used from these studies as these do not (less likely) account for recovery/ recolonisation.

In both field studies, the community NOER is 21 g a.s./ha.
The NOER population is:

Study in NL: 5.1 g a.s./ha

Study in SW-FR: 1.7 g a.s./ha

The lowest from these values can be used in the risk assessment, i.e. 1.7 g a.s./ha.

It was extensively discussed in the pesticide peer review meeting whether a safety factor should be applied to this value to account from uncertainties in extrapolating the results of field studies to the realistic worst case field situation. Overall, the majority of the experts agreed that no additional safety

factor is required in this case given that the endpoint is a NOER and that two studies (accounting for the representativeness of the taxa) are available.

Refined potential exposure:

In the original DAR, the calculation of the off-field PEC was confusing, as reference was made to the term 'correction factor' while this is only appropiate for extended laboratory studies and not for field studies. This term has therefore been removed from the table below. The possible need for a safety factor, accounting for uncertainty when using field studies in the risk assessment, has already been discussed above. The vegetation distribution factor is not applicable because of the 3-D study design. The refined off-field exposure is calculated in the table below. For the use in hops, a risk is identified using the default drift value; therefore the exposure at increasing distances from the crop (and therefore decreasing drift values) is also shown.

Table 2.6.3.2-08 Refined exposure calculation for off-field risk assessment

Crop / no. of applications	Appl. rate [g a.i./ha]	MAF	Distance from crop	Drift [%]	off-field PECmax. [g/ha]	Endpoint based two full-fauna field studies [g/ha]
Hops / 1	150	1	3*	19.33	29	1.7
	150	1	5	11.57	17	1.7
	150	1	10	5.77	8.7	1.7
	150	1	15	3.84	5.8	1.7
	150	1	20	1.79	2.7	1.7
	150	1	30	0.56	0.84	1.7
Lettuce / 1	125	1	1*	2.77	3.5	1.7
	125	1	5	0.57	0.71	1.7

*Default

Table 2.6.3.2-08 shows that ~~the off-crop exposure is below the relevant off-field endpoint of 5.1 g a.s./ha for the use in lettuce. Therefore, the off-field risk from the use in lettuce is acceptable.~~

~~t~~he expected exposure (29 g a.s./ha) is above the relevant endpoint (1.7 ~~5.1~~ g a.s./ha) for the use in hops at the default distance from the crop. The table shows that a buffer zone of at least 30~~20~~ m would be required for the exposure value to fall below the required level. This means that acceptable use can be achieved based on the European guidance. The off-field risk from the use in hops is acceptable provided that a buffer zone of 30~~20~~ m is used.

For lettuce, the expected exposure (3.5 g a.s./ha) is above the relevant endpoint (1.7 ~~5.1~~ g a.s./ha) at the default distance from the crop. The table shows that a buffer zone of at least 5 m would be required for the exposure value to fall below the required level.

Note that other options for risk mitigation may be possible (e.g. drift reducing nozzles or the presence of off-crop in-field buffer zones which would give the option to use a higher endpoint). Risk mitigation measures are set at Member State level.

2.6.4 Effects on earthworms and other soil macro-organisms

2.6.4.1 Effects on earthworms

Procedures for risk assessment were in agreement with the recommendations in the Guidance Document on Terrestrial Ecotoxicology under Council Directive 91/414/EEC (Working Document Sanco/10329/2002 rev 2 final, 17 October 2002). Two soil metabolites require further consideration according to the fate section: DFA and 6-CNA.

Acute risk to earthworms

The table below presents a summary of the acute toxicity studies on earthworms.

Table 2.6.4.1-01 Acute effects of BYI 02960 and relevant metabolites on earthworms

Test species	Test design	Ecotoxicological endpoint			Reference
BYI 02960					
Eisenia fetida	acute, 14 d (10% peat in test soil)	LC_{50}	185.6	mg a.i./kg dws	Leicher (2010) KIIA 8.9.1/01
BYI 02960 SL 200 G					
Eisenia fetida	acute, 14 d (5% peat in test soil)	LC_{50}	121	mg a.i./kg dws	Leicher (2010) KIIIA 10.6.2/01
DFA					
Eisenia fetida	acute, 14 d (10% peat in test soil)	LC_{50}	> 958	mg p.m./kg dws	Leicher (2007) KIIA 8.9.1/02
6-CAN					
Eisenia fetida	acute, 14 d (10% peat in test soil)	LC_{50}	> 1000	mg p.m./kg dws	Wetton (1999) KIIA 8.9.1/03

dws = dry weight soil
a.i. = active ingredient; p.m. = pure metabolite

For lipophilic substances (log POW > 2) the Terrestrial Guidance Document recommends to apply an additional assessment factor of 2 for the ecotoxicological endpoints (LC50, NOEC), if the study was conducted in artificial soil with a high content of organic matter (i.e. 10 % peat), to consider the possible sorption of these compounds to the organic matter. However, BYI 02960 and its metabolites have a log POW < 2 and no additional assessment factor has to be applied.

The toxicity values are compared with the PECsoil values from section B.8.3 (maximum concentration after multiple year use: $PEC_{initial}$ after one application + $PEC_{accumulation}$). The $PEC_{initial}$ is expressed over 5 cm. For hops, the $PEC_{accumulation}$ is expressed over 5 cm (perennial crop without tillage). For lettuce, the $PEC_{accumulation}$ is expressed over 20 cm (annual crop with tillage). The acute TER values are presented in Table 2.6.4.1-02.

Table 2.6.4.1-02 TER_{acute} calculations for earthworms

Compound test design	End point	[mg/kg soil]	$PEC_{max,accu}$ [mg/kg soil]	TER_{acute}	Trigger	Refined risk assessment?
Hops						
BYI 02960	LC_{50}	185.6	0.160	2.3E+3	10	
BYI 02960 SL 200	LC_{50}	121	0.160	7.6E+2	10	No
DFA	LC_{50}	>958	0.009	> 11E+4	10	
6-CNA	LC_{50}	>1000	0.007	> 14E+4	10	
Lettuce biennial						
BYI 02960	LC50	185.6	0.141	1.3E+3	10	
BYI 02960 SL 200	LC50	121	0.141	8.6E+2	10	No
DFA	LC50	>958	0.014	> 68E+3	10	
6-CNA	LC50	>1000	0.012	≥ 83E+3	10	
Lettuce annual						
BYI 02960	LC50	185.6	0.063	2.9E+3	10	
BYI 02960 SL 200	LC50	121	0.063	1.9E+3	10	No
DFA	LC50	>958	0.006	> 16E+4	10	
6-CNA	LC50	>1000	0.005	> 20E+4	10	

The TER values in Table 2.6.4.1-02 are far above the Annex VI 91/414 EEC trigger of 10. Hence the acute risk to earthworms is considered to be acceptable.

Chronic risk to earthworms

The table below presents a summary of the chronic toxicity studies on earthworms.

Table 2.6.4.1-03 Chronic effects of BYI 02960 and relevant metabolites on earthworms

Test species	Test design	Ecotoxicological endpoint	Reference
BYI 02960 SL 200 G			
Eisenia fetida	reproduction, 56 d (10% peat in test soil)	NOEC 1.5 mg a.i./kg dws	Leicher (2010) KIIIA1 10.6.3/01
DFA			
Eisenia fetida	reproduction, 56 d (10% peat in test soil) mixing	NOEC 59 mg p.m./kg dws	Leicher (2010) KIIA 8.9.2/02
6-CNA			
Eisenia fetida	reproduction, 56 d (10% peat in test soil) mixing	NOEC 95 mg p.m./kg dws	Leicher (2011) KIIA 8.9.2/03

dws = dry weight soil
a.i. = active ingredient; p.m. = pure metabolite

The toxicity values are compared with the PECsoil values from section B.8.3 (maximum concentration after multiple year use: $PEC_{initial}$ after one application + $PEC_{accumulation}$). The $PEC_{initial}$ is expressed over

5 cm. For hops, the $PEC_{accumulation}$ is expressed over 5 cm (perennial crop without tillage). For lettuce, the $PEC_{accumulation}$ is expressed over 20 cm (annual crop with tillage). The long-term TER values are presented in Table 2.6.4.1-04.

Table 2.6.4.1-04 $TER_{long-term}$ calculations for earthworms

Compound test design	End point	[mg/kg soil]	$PEC_{max,accu}$ [mg/kg soil]	TER_{lt}	Trigger	Refined risk assessment?
Hops						
BYI 02960 SL 200	NOEC	1.5	0.160	9.4	5	No
DFA	NOEC	59	0.009	6.6E+3	5	
6-CNA	NOEC	95	0.007	14E+3	5	
Lettuce biennial						
BYI 02960 SL 200	NOEC	1.5	0.141	11	5	No
DFA	NOEC	59	0.014	4.2E+3	5	
6-CNA	NOEC	95	0.012	7.9E+3	5	
Lettuce annual						
BYI 02960 SL 200	NOEC	1.5	0.063	24	5	No
DFA	NOEC	59	0.006	9.8E+3	5	
6-CNA	NOEC	95	0.005	19E+3	5	

The TER values in Table 2.6.4.1-04 are above the Annex VI 91/414 EEC trigger of 5. Hence the chronic risk to earthworms is considered to be acceptable.

Field studies with earthworms

A field study with earthworms was performed nevertheless. In this one year earthworm field study, BYI 02960 SL 200 G was sprayed on grassland at 300, 600 and 1500 g a.i./ha corresponding to measured concentrations of 271, 472 and 1234 µg/kg soil (mean of four plots). Reduction of abundance (-33%) and biomass (-38%) at 1500 g a.i./ha and biomass at 600 g a.i./ha (-36%) after 1 month were seen, but there was full recovery of earthworm population after 11 months. The measured concentrations in soil at the start of the study (up to 1.234 mg/kg soil measured over 10 cm, see remarks to the field study above) cover the expected concentrations at the proposed uses (up to 0.160 mg/kg soil). ~~The study confirms the expected acceptable risk to earthworms.~~ However, the study was considered invalid by the experts of the pesticide peer review meeting of December 2014. Therefore, this study cannot be used for the risk assessment. This has no influence on the outcome of the risk assessment, since this was already acceptable based on laboratory studies.

2.6.4.2 Effects on soil non-target macro-organisms (IIIA 10.6.6)

Summary and risk assessment

The Guidance Document on Terrestrial Ecotoxicology Under Council Directive 91/414/EEC (Sanco 10329/2002, rev 2 final) states that a 'higher degree of scrutiny' for the soil organism risk assessment is required if the field DT90 values in soil are >100 days. The field DT90 values for BYI 02960 and the laboratory DT90 (no field studies available) for metabolites DFA and 6-CNA are >100 days. Therefore, studies with *Folsomia candida* and *Hypoaspis aculeifer* were performed with the formulated product and the two metabolites. See Table 2.6.4.1.

Table 2.6.4.1 Effects on other soil non-target macro-organisms

Test species	Test design	Ecotoxicological endpoint			Reference
BYI 02960 SL 200 G					
Folsomia candida	chronic, 28 d (5% peat in test soil)	NOEC	1.44	mg a.s./kg dws	Frommholz (2009) KIIA 8.14/01, KIIIA1 10.6.6/01
Hypoaspis aculeifer	chronic, 14 d (5% peat in test soil)	NOEC	≥ 170	mg a.s./kg dws	Kratz (2010) KIIA 8.14/04, KIIIA1 10.6.6/02
DFA					
Folsomia candida	chronic, 28 d (5% peat in test soil)	NOEC	≥ 95.8	mg p.m./kg dws	Frommholz (2010) KIIA 8.14/02
Hypoaspis aculeifer	chronic, 14 d (5% peat in test soil)	NOEC	≥ 958	mg p.m./kg dws	Kratz (2010) KIIA 8.14/05
6-CNA					
Folsomia candida	chronic, 28 d (5% peat in test soil)	NOEC	90	mg p.m./kg dws	Frommholz (2010) KIIA 8.14/03
Hypoaspis aculeifer	chronic, 14 d (5% peat in test soil)	NOEC	≥ 100	mg p.m./kg dws	Kratz, A. (2011) KIIA 8.14/06

dws = dry weight soil
p.m. = pure metabolite

The toxicity values are compared with the PECsoil values from section B.8.3 (maximum concentration after multiple year use: $PEC_{initial}$ after one application + $PEC_{accumulation}$). The $PEC_{initial}$ is expressed over 5 cm. For hops, the $PEC_{accumulation}$ is expressed over 5 cm (perennial crop without tillage). For lettuce, the $PEC_{accumulation}$ is expressed over 20 cm (annual crop with tillage). The long-term TER values are presented in Table 2.6.4.2-08 and -09.

Table 2.6.4.2--08 $TER_{long-term}$ calculations for *Folsomia candida*

Compound test design	End point	[mg/kg soil]	$PEC_{max,accu}$ [mg/kg soil]	TER_{lt}	Trigger	Refined risk assessment?
Hops						
BYI 02960 SL 200	NOEC	1.44	0.160	9.0	5	No
DFA	NOEC	≥ 95.8	0.009	11E+3	5	
6-CNA	NOEC	90	0.007	13E+3	5	
Lettuce biennial						
BYI 02960 SL 200	NOEC	1.44	0.141	10	5	No
DFA	NOEC	≥ 95.8	0.014	6.8E+3	5	
6-CNA	NOEC	90	0.012	7.5E+3	5	
Lettuce annual						
BYI 02960 SL 200	NOEC	1.44	0.063	23	5	No
DFA	NOEC	≥ 95.8	0.006	16E+3	5	
6-CNA	NOEC	90	0.005	18E+3	5	

Table 2.6.4.2--09 $TER_{long-term}$ calculations for *Hypoaspis aculeifer*

Compound test design	End point	[mg/kg soil]	$PEC_{max,accu}$ [mg/kg soil]	TER_{lt}	Trigger	Refined risk assessment?
Hops						
BYI 02960 SL 200	NOEC	≥ 170	0.160	≥ 1.1E+3	5	No
DFA	NOEC	≥ 958	0.009	≥ 11E+4	5	
6-CNA	NOEC	≥ 100	0.007	≥ 14E+3	5	
Lettuce biennial						
BYI 02960 SL 200	NOEC	≥ 170	0.141	≥ 1.2E+3	5	No
DFA	NOEC	≥ 958	0.014	≥ 68E+3	5	
6-CNA	NOEC	≥ 100	0.012	≥ 8.3E+3	5	
Lettuce annual						
BYI 02960 SL 200	NOEC	≥ 170	0.063	≥ 2.7E+3	5	No
DFA	NOEC	≥ 958	0.006	≥ 16E+4	5	
6-CNA	NOEC	≥ 100	0.005	≥ 20E+3	5	

The TER values in Table 2.6.4.2-08 and -09 are above the Annex VI 91/414 EEC trigger of 5. Hence the chronic risk to soil macro-organisms other than earthworms is considered to be acceptable.

Effects on organic matter breakdown

Two litterbag studies, one similating spray treatment and one seed treatment, both performed in Germany, show no adverse effects on organic matter breakdown after exposure to ca. 0.24 mg BYI 02960/kg soil dw. These tested concentrations are higher than the calculated maximum concentrations of at most 0.160 mg/kg a.s. (measured over 10 cm) for the proposed uses in hops and lettuce ($PEC_{initial}$ expressed over 5 cm + $PEC_{accumulation}$ expressed over 5 (hops) or 20 (lettuce) cm). Therefore the risk to organic matter breakdown is considered to be low.

2.6.5 Effects on soil micro-organisms

Laboratory studies on microbial turnover are available for the active substance BYI 02960, the formulation BYI 02960 SL 200 G, and the metabolite 6-CNA (N-turnover only).
The results indicate that BYI 02960 and BYI 02960 SL 200 G have no adverse impact on microbial C- and N-turnover in soil. NOECs were clearly above the expected exposure in soil.
Overall, it can be concluded that the functioning of soil micro-organisms is not at risk if BYI 02960 SL 200 G is applied according to the recommended use pattern.

The toxicity of BYI 02960 SL 200 G on soil non-target micro-organisms is summarised in the table below.

Table 2.6.5-01 Effects on soil non-target micro-organisms

Test species	Test design	Ecotoxicological endpoint		Reference
BYI 02960 SL 200 G				
C-cycle	28 d	no influence	16.59 µL prod/kg dws (≡3.335 mg a.s./kg dws)	Frommholz (2010) KIIIA1 10.7.1/01
N-cycle	28 d	no influence	16.59 µL prod/kg dws (≡3.335 mg a.s./kg dws)	Frommholz (2010) KIIIA1 10.7.1/02
BYI 02960				
N-cycle	28 d	no influence	3.8 mg a.i./kg dws	Frommholz (2009) KIIA 8.10.1/01
C-cycle	28 d	no influence	3.8 mg a.i./kg dws	Schulz (2011) KIIA 8.10.2/01
6-CNA				
N-cycle	28 d	no influence	1.33 mg p.m./kg dws	Frommholz (2011) KIIA 8.10.1/02

Risk assessment

According to current regulatory requirements the risk is acceptable, if the effect of the recommended application rate of a compound / product on nitrogen or carbon mineralisation is < 25% after 100 days. In the studies, deviations from the control did not exceed 25% after 28 days, at tested concentrations which are higher than the calculated maximum concentrations of at most 0.160 mg/kg a.s. and 0.012 mg 6-CNA for the proposed uses.

The metabolite 6-CNA was shown to be of general low toxicity for soil organisms (earthworm LC50 >1000 mg/kg, NOEC 95 mg/kg; Hypoaspis NOEC 100 mg/kg; Folsomia NOEC 90 mg/kg). The NOEC of the metabolite 6-CNA for microbial N-turnover was determined to be 111- fold higher than the worst case PEC in soil for 6-CNA. The high margin of safety indicates that microbial C-turnover is not at risk due to formation of 6-chloronicotinic acid in soil.
Similar to 6-chloronicotinic acid the metabolite DFA acid was shown to be of general low toxicity for soil organisms (earthworm LC50 >958 mg/kg, NOEC 59 mg/kg). Assuming a 10-fold higher toxicity of DFA in comparison with to 6-CNA with regard to microbial C- and N-turnover, the risk could still be considered as acceptable.
Furthermore, the metabolites are likely to have been formed in the litterbag studies, in which no risk was identified to organic matter breakdown.
Based on the above, no further studies are required. The risk to soil micro-organisms is considered to be low.

2.6.6 Effects on other non-target organisms (flora and fauna)

The risk assessment is based on the “Guidance Document on Terrestrial Ecotoxicology”, (SANCO/10329/2002 rev2 final, 2002). It is restricted to off-field situations, as non-target plants are non-crop plants located outside the treated area. Spray drift from the treated areas may lead to residues of a product in off-crop areas. Exposure is not relevant for glasshouse uses.

In the case of a non-herbicide, screening results and/or Tier 1 studies give first information about the likelihood for terrestrial plant effects. The risk can be considered acceptable if there are no data indicating more than 50% phytotoxic effect at the maximum application rate.

Seedling emergence (Gosch (2010), KIIIA1 10.8.1.3/01) and vegetative vigour studies Gosch (2010), KIIIA1 10.8.1.2/01) have been conducted with BYI 02960 SL 200 G following OECD testing guidelines 208 and 227, respectively (see Annex Points IIIA1 10.8.1.3 and 10.8.1.2). Each study included 11 species which were tested at the maximum application rate of 410 g a.i./ha.
In the case of BYI 02960 SL 200 G neither the tier 1 seedling emergence nor the vegetative vigour studies showed phytotoxic effects >50% at the maximum application rate of 410 g a.i./ha. Therefore, the ER50 values are set at >410 g a.s./ha.

For the proposed field uses in hops and lettuce, the following scenario is used to describe the exposure to non-target plants:

off-field exposure= Application rate * MAF * drift factor

For the MAF and drift factor, similar assumptions are made as for the off-field risk assessment for non-target arthropods.

As the proposed uses of BYI 02960 SL 200 formulation involves one application only, the multiple application factor (MAF) is 1. Drift values are 19.33% for hops (3 m distance) and 2.77% for lettuce (field crops, 1m distance).

The calculated exposure for the respective uses and the TER values are given in Table 2.6.6-01.

Table 2.6.6-01 Exposure values and TERs for non-target plants

Crop	Max. single dose [g a.s./ha]	number of applications	MAF	Drift [%]	Exposure [g a.s./ha]	ER_{50} [g a.s./ha]	TER	Trigger
hops	150	1	1	19.33	30	>410	>14	5
lettuce	125	1	1	2.77	3.5	>410	>118	5

1: drift in vegetables, > 50 cm.

For both uses, the TERs are above the trigger of 5. A low risk for non-target plants is expected.

2.6.7 Effects on biological methods of sewage treatment

Emission of flupyradifurone to sewage treatment plants may occur following the proposed use of Sivanto in glasshouses. The expected concentration in the STP is not calculated because EU harmonised guidance is lacking. However, based on the results of the activated sludge respiration test, which obtained an EC_{50} > 962 mg a.s./L, no effect on biological methods of sewage treatment are expected.

2.7 Efficacy

The data presented by the applicant supports two representative uses for Flupyradifurone in the EU: Control of *Nasonovia ribisnigri* in lettuce (field and greenhouse) and Phorodon humuli in hops.

Mode of action

Flupyradifurone interacts with insect nicotinic acetylcholine receptors, a class of neurotransmitter-gated cation channels which are involved in excitatory neurotransmission, a target also known for neonicotinoid insecticides.

After uptake into the plant, Flupyradifurone is translocated acropetally in the xylem, in direction of the transpiration stream and is translaminarily distributed into adjacent plant cells.

2.7.1 Dose justification and efficacy

For approval of a new active substance efficacy data is required on one or more representative uses on a widely grown crop in each zone of at least one plant protection product containing the active substance, showing adequate efficacy. The principal objective of the efficacy evaluation of an active substance is to confirm that the dose rates are realistic. The dossier contains trials for the Maritime and north-eastern zone for hop, and data for the Mediterranean and maritime zone for lettuce. The submitted gap is adequate, in that it concerns two very different crops that likely represent worst case situations for the evaluation of other aspects.

No trials were presented from the south-eastern zone. It is not expected that trials from this zone would have presented a worst case situation for efficacy or phytotoxicity when compared to the submitted trials.

Hop

Dose justification trials are available from the maritime zone (Germany and the Czech Republic) and the north-east zone (Poland). The claimed dose rate is 0.75 L/ha (0,150 g a.s/ha). Only trials with sufficient pest pressure were taken into consideration.

In hop high efficacy was found at all tested dose rates, some effect of the dose rate was seen as the lower dose rates than the requested dose rate in general showed equal to or lower efficacy than the reference products while the proposed dose rate showed higher than or equal efficacy.

For hop cultivation it is necessary to reach an efficacy against damson hop aphid close to 100% (to reach acceptable cones quality at harvest), the rate of 0.75 L/ha Flupyradifurone SL200 can be considered as the optimum dose rate, and provided good efficacy.

Lettuce

Nasonovia ribisnigri is a difficult aphid to control, as in lettuce, it is often found concealed between the leaves, it thus provides an adequate test for the product.

11 Minimum Effective Dose trials were presented by the applicant: 7 carried out in the Maritime zone, 4 in the Mediterranean zone. All of them were carried out under field conditions. The intended dose rate is125 g a.s/ha

In general, in the field, little effect of the dose rate was found at the first assessments in the maritime zone trials, but higher dose rates performed better at later assessment dates. In the mediteranean zones a dose response was found at dose rates from 75 to 150 g a.s./ha, the increase in efficacy between 125 and 150 g a.s./ha was only marginal. When compared to reference products based on thyacloprid, imidacloprid or pymetrozine, the dose rate of 125 g a.s. in general performed equal or better.

The reference product based on spirotetramat in general provided longer lasting control than Flupyradifurone 200 SL and the other reference product, but initial efficacy was often lower.

The proposed dose rate of 125 g a.s/ha provided good control (initial and lasting efficacy) and when compared to the other tested dose rates, should be considered as the optimum dose rate for control of *Nasonovia ribisnigri* in lettuce in the field.

All submitted trials for lettuce were performed under field conditions, as such the greenhouse use can not be evaluated based on the submitted data. The aim of the efficacy evaluation for approval of the active substance is to establish if the GAP is realistic. While no large differences in dose rate are expected between the indoor and outdoor use in lettuce, the dose rate could be different because of differences in pest pressure, or higher sensitivity to phytotoxicity because of different growing conditions.

For approval of a new active substance efficacy data is required on one or more representative uses on a widely grown crop in each zone of at least one plant protection product containing the active substance, showing adequate efficacy. Without the greenhouse use for lettuce, the submitted data for approval of the active substance can still be considered sufficient for efficacy.

2.7.2 Possible occurrence of the development of resistance

No data was submitted by the applicant. Flupyradifurone has a mode of action similar to the neonicotinoids. It does not yet have a IRAC classification, but will likely be classified in one of the subgroups of group 4.

Resistance risk would be expected to be similar to neonicotinoid insecticides.

Resistance risk and resistance management strategies will be evaluated in more detail during product registration.

2.7.3 Effects on quality of plants or plant products

No data was submitted by the applicant. No phytotoxic effects were found in the dose justification trials, an effect on quality of plants or plant products is therefore not expected.
Effects on quality of plants or plant products will be evaluated in more detail during product registration.

2.7.4 Effects on transformation processes

No data was submitted by the applicant.
Effects on transformation processes will be evaluated in more detail during product registration.

2.7.5 Effects on the yield of treated plants or plant products

No data was submitted by the applicant. No phytotoxic effects were found in the dose justification trials. Effects on yield will be evaluated in more detail during product registration.

2.7.6 Phytotoxicity to target plants or target plant products

Crop safety in lettuce and hops was considered in all effectiveness and dose justification trials. Eight varieties of lettuce and 7 varieties of hop were included in the trials.

Lettuce

In lettuce, all trials were performed under field conditions, whereas greenhouse conditions would present a more worst case situation for the assessment of phytotoxicity. The main goal of evaluation of efficacy for registration of an active substance is to check if the requested dose rates are realistic, this is important for determination of the risk envelope for the other aspects. Phytotoxic effects could place an upper limit on the dose rates if severe enough. This may have an effect on efficacy, but will result in less worse case situations for the other aspects.
For the purpose of creating a realistic gap for registration of the active substance the submitted phytoxicity data can be considered sufficient. For registration of the product under greenhouse conditions additional trials would be required.

Hops:

In 4 trials in hop in the Czech Republic, a 2N dose rate was included in the trials. In none of the efficacy trials, including those with the 2N dose rate, phytotoxic effects were seen.

2.7.7 Impact on succeeding crops, adjacent crops and on treated plants or plant products used for propagation

Based on the evaluation of data submitted by the applicant, the effects on adjacent crops and effects on treated plants and plant products used for propagation were found to be acceptable.

APPENDIX 1

FLUPYRADIFURONE

PART 1: Standard terms and abbreviations

PART 2: Organisations and publications

PART 3: Preparation (formulation) types and codes

Part 1	**Standard terms and abbreviations**
A	ampere
ACh	acetylcholine
AChE	acetylcholinesterase
ADI	acceptable daily intake
ADP	adenosine diphosphate
AE	acid equivalent
AFID	alkali flame-ionisation detector or detection
A/G	albumin/globulin ratio
ai	active ingredient
ALD_{50}	approximate median lethal dose, 50%
ALT	alanine aminotransferase (SGPT)
AOEL	acceptable operator exposure level
AMD	automatic multiple development
ANOVA	analysis of variance
AP	alkaline phosphatase
approx	approximate
ARC	anticipated residue contribution
ARfD	acute reference dose
as	active substance
AST	aspartate aminotransferase (SGOT)
ASV	air saturation value
ATP	adenosine triphosphate
BCF	bioconcentration factor
bfa	body fluid assay
BOD	biological oxygen demand
bp	boiling point
BSAF	biota-sediment accumulation factor
BSE	bovine spongiform encephalopathie
BSP	bromosulfophthalein
Bt	bacillus thuringiensis
Bti	bacillus thuringiensis israelensis
Btk	bacillus thuringiensis kurstaki
Btt	bacillus thuringiensis tenebrionis
BUN	blood urea nitrogen
bw	body weight
c	centi- (x 10^{-2})
°C	degree Celsius (centigrade)
CA	controlled atmosphere
CAD	computer aided design
CADDY	computer aided dossier and data supply (an electronic dossier interchange and archiving format)
cd	candela
CDA	controlled drop(let) application
cDNA	complementary DNA
CEC	cation exchange capacity
cf	confer, compare to
CFU	colony forming units

ChE	cholinesterase
CI	confidence interval
CL	confidence limits
cm	centimetre
CNS	central nervous system
COD	chemical oxygen demand
CPK	creatinine phosphatase
cv	coefficient of variation
Cv	ceiling value
CXL	Codex Maximum Residue Limit (Codex MRL)
d	day
DAA	days after application
DALA	days after last application
DAT	days after treatment
DES	diethylstilboestrol
DFR	dislodgeable foliar residue
DMSO	dimethylsulfoxide
DNA	deoxyribonucleic Acid
dna	designated national authority
DO	dissolved oxygen
DOC	dissolved organic carbon
dpi	days post inoculation
DRES	dietary risk evaluation system
DT_{50}	period required for 50 percent dissipation (define method of estimation)
DT_{90}	period required for 90 percent dissipation (define method of estimation)
dw	dry weight
DWQG	drinking water quality guidelines
ε	decadic molar extinction coefficient
EC_{50}	median effective concentration
ECD	electron capture detector
ECU	European currency unit
ED_{50}	median effective dose
EDI	estimated daily intake
ELISA	enzyme linked immunosorbent assay
e-mail	electronic mail
EMDI	estimated maximum daily intake
EPMA	electron probe micro analysis
ERC	environmentally relevant concentration
ERL	extraneous residue limit
F	field
F_0	parental generation
F_1	filial generation, first
F_2	filial generation, second
FIA	fluorescence immunoassay
FID	flame ionisation detector
FOB	functional observation battery
fp	freezing point
FPD	flame photometric detector
FPLC	fast protein liquid chromatography

g	gram
G	glasshouse
GAP	good agricultural practice
GC	gas chromatography
GC-EC	gas chromatography with electron capture detector
GC-FID	gas chromatography with flame ionisation detector
GC-MS	gas chromatography-mass spectrometry
GC-MSD	gas chromatography with mass-selective detection
GEP	good experimental practice
GFP	good field practice
GGT	gamma glutamyl transferase
GI	gastro-intestinal
GIT	gastro-intestinal tract
GL	guideline level
GLC	gas liquid chromatography
GLP	good laboratory practice
GM	geometric mean
GMO	genetically modified organism
GMM	genetically modified micro-organism
GPC	gel-permeation chromatography
GPPP	good plant protection practice
GPS	global positioning system
GSH	glutathion
GV	granulosevirus
h	hour(s)
H	Henry's Law constant (calculated as a unitless value) (see also K)
ha	hectare
Hb	haemoglobin
HCG	human chorionic gonadotropin
Hct	haematocrit
HDT	highest dose tested
hL	hectolitre
HEED	high-energy electron diffraction
HID	helium ionisation detector
HPAEC	high performance anion exchange chromatography
HPLC	high pressure liquid chromatography or high performance liquid chromatography
HPLC-MS	high pressure liquid chromatography - mass spectrometry
HPPLC	high pressure planar liquid chromatography
HPTLC	high performance thin layer chromatography
HR	Highest Residue
HRGC	high resolution gas chromatography
H_S	Shannon-Weaver index
Ht	haematocrit
I	indoor
I_{50}	inhibitory dose, 50%
IC_{50}	median immobilisation concentration or median inhibitory concentration
ICM	integrated crop management
ID	ionisation detector

IEDI	international estimated daily intake
IESTI	international estimated short term intake
IGR	insect growth regulator
im	intramuscular
inh	inhalation
ip	intraperitoneal
IPM	integrated pest management
IR	infrared
ISBN	international standard book number
ISSN	international standard serial number
iv	intravenous
IVF	in vitro fertilisation
k	kilo
K	Kelvin or Henry's Law constant (in atmospheres per cubic meter per mole, see also H)
K_{ads}	adsorption constant
K_{des}	apparent desorption coefficient
K_{oc}	organic carbon adsorption coefficient
K_{om}	organic matter adsorption coefficient
kg	kilogram
L	litre
LAN	local area network
LASER	light amplification by stimulated emission of radiation
LBC	loosely bound capacity
LC	liquid chromatography
LC-MS	liquid chromatography- mass spectrometry
LC_{50}	lethal concentration, median
LCA	life cycle analysis
LC_{Lo}	lethal concentration low
LC-MS-MS	liquid chromatography with tandem mass spectrometry
LD_{50}	lethal dose, median; dosis letalis media
LD_{Lo}	lethal dose low
LDH	lactate dehydrogenase
LOAEC	lowest observable adverse effect concentration
LOAEL	lowest observable adverse effect level
LOD	limit of detection
LOEC	lowest observable effect concentration
LOEL	lowest observable effect level
LOQ	limit of quantification (determination)
LPLC	low pressure liquid chromatography
LSC	liquid scintillation counting or counter
LSD	least squared denominator multiple range test
LSS	liquid scintillation spectrometry
LT	lethal threshold
m	metre
M	molar
µm	micrometer (micron)
MC	moisture content
MCH	mean corpuscular haemoglobin

MCHC	mean corpuscular haemoglobin concentration
MCV	mean corpuscular volume
MDL	method detection limit
MFO	mixed function oxidase
µg	microgram
mg	milligram
MHC	moisture holding capacity
min	minute(s)
mL	millilitre
MLT	median lethal time
MLD	minimum lethal dose
mm	millimetre
mo	month(s)
mol	Mole(s)
MOS	margin of safety
mp	melting point
MRE	maximum residue expected
MRL	maximum residue level or limit
mRNA	messenger ribonucleic acid
MS	mass spectrometry
MSDS	material safety data sheet
MTD	maximum tolerated dose
n	normal (defining isomeric configuration) or number of observations
NAEL	no adverse effect level
nd	not detected
NEDI	national estimated daily intake
NESTI	national estimated short term intake
NEL	no effect level
NERL	no effect residue level
ng	nanogram
nm	nanometer
NMR	nuclear magnetic resonance
no	number
NOAEC	no observed adverse effect concentration
NOAEL	no observed adverse effect level
NOEC	no observed effect concentration
NOED	no observed effect dose
NOEL	no observed effect level
NOIS	notice of intent to suspend
NPD	nitrogen-phosphorus detector or detection
NPV	nuclear polyhedrosis virus
NR	not reported
NTE	neurotoxic target esterase
OC	organic carbon content
OCR	optical character recognition
ODP	ozone-depleting potential
ODS	ozone-depleting substances
OM	organic matter content
op	organophosphorous pesticide

Pa	Pascal
PAD	pulsed amperometric detection
2-PAM	2-pralidoxime
PBI	plant back interval
pc	paper chromatography
PC	personal computer
PCV	haematocrit (packed corpuscular volume)
PEC	predicted environmental concentration
PEC_A	predicted environmental concentration in air
PEC_S	predicted environmental concentration in soil
PEC_{SW}	predicted environmental concentration in surface water
PEC_{GW}	predicted environmental concentration in ground water
PED	plasma-emissions-detector
pH	pH-value
PHED	pesticide handler's exposure data
PHI	pre-harvest interval
PIC	prior informed consent
pic	phage inhibitory capacity
PIXE	proton induced X-ray emission
pKa	negative logarithm (to the base 10) of the dissociation constant)
PNEC	predicted no effect concentration
po	by mouth
P_{OW}	partition coefficient between n-octanol and water
POP	persistent organic pollutants
ppb	parts per billion (10^{-9})
PPE	personal protective equipment
ppm	parts per million (10^{-6})
ppp	plant protection product
ppq	parts per quadrillion (10^{-24})
ppt	parts per trillion (10^{-12})
PSP	phenolsulfophthalein
PrT	prothrombin time
PRL	practical residue limit
PT	prothrombin time
PTDI	provisional tolerable daily intake
PTT	partial thromboplastin time
QSAR	quantitative structure-activity relationship
r	correlation coefficient
r^2	coefficient of determination
RBC	red blood cell
REI	restricted entry interval
Rf	retardation factor
RfD	reference dose
RH	relative humidity
RL_{50}	median residual lifetime
RNA	ribonucleic acid
RP	reversed phase
rpm	rotations per minute
rRNA	ribosomal ribonucleic acid
RRT	relative retention time

RSD	relative standard deviation
s	second
SAC	strong adsorption capacity
SAP	serum alkaline phosphatase
SAR	structure/activity relationship
SBLC	shallow bed liquid chromatography
sc	subcutaneous
sce	sister chromatid exchange
SD	standard deviation
se	standard error
SEM	standard error of the mean
SEP	standard evaluation procedure
SF	safety factor
SFC	supercritical fluid chromatography
SFE	supercritical fluid extraction
SIMS	secondary ion mass spectroscopy
SOP	standard operating procedures
sp	species (only after a generic name)
SPE	solid phase extraction
SPF	specific pathogen free
spp	subspecies
sq	square
SSD	sulphur specific detector
SSMS	spark source mass spectrometry
STEL	short-term exposure limit
STMR	supervised trials median residue
t	tonne (metric ton)
$t_{½}$	half-life (define method of estimation)
T_3	tri-iodothyroxine
T_4	thyroxin
TADI	temporary acceptable daily intake
TBC	tightly bound capacity
TCD	thermal conductivity detector
TC_{Lo}	toxic concentration, low
TID	thermionic detector, alkali flame detector
TD_{Lo}	toxic dose low
TDR	time domain reflectrometry
TER	toxicity exposure ration
TER_I	toxicity exposure ration for initial exposure
TER_{ST}	toxicity exposure ration following repeated exposure
TER_{LT}	toxicity exposure ration following chronic exposure
tert	tertiary (in a chemical name)
TEP	typical end-use product
TGGE	temperature gradient gel electrophoresis
TIFF	tag image file format
TLC	thin layer chromatography
Tlm	median tolerance limit
TLV	threshold limit value
TMDI	theoretical maximum daily intake
TMRC	theoretical maximum residue contribution

TMRL	temporary maximum residue limit
TOC	total organic carbon
Tremcard	Transport emergency card
tRNA	transfer ribonucleic acid
TSH	thyroid stimulating hormone (thyrotropin)
TWA	time weighted average
UDS	unscheduled DNA synthesis
UF	uncertainty factor (safety factor)
ULV	ultra low volume
UV	ultraviolet
v/v	volume ratio (volume per volume)
WBC	white blood cell
wk	week
wt	weight
w/v	weight per volume
ww	wet weight
w/w	weight per weight
XRFA	X-ray fluorescence analysis
yr	year
<	less than
=	less than or equal to
>	greater than
=	greater than or equal to

Part 3 Preparation (formulation) types and codes

Code	*Description*	*Definition*
AB	Grain bait	Special forms of bait.
AE	Aerosol dispenser	A container-held preparation which is dispersed generally by a propellant as fine droplets/particles upon actuation of a valve.
AL	Other liquids to be applied undiluted	Self defining.
BB	Block blits	Special forms of bait.
BR	Briquette	Solid block designed for controlled release of active ingredient into water.
CB	Bait concentrate	A solid or liquid intended for dilution before use as a bait.
CG	Encapsulated granule	A granule with a protective or release controlling coating.
CS	Capsule suspension	A stable suspension of capsules in a fluid normally intended for dilution with water before use.
DC	Dispersible concentrate	A liquid homogeneous preparation to be applied as a solid dispersion after dilution in water.
DP	Dustable powder	A free-flowing powder suitable for dusting.
DS	Powder for dry seed treatment	A powder for application in the dry state directly to seed.
EC	Emulsifiable concentrate	A liquid, homogenous preparation to be applied as an emulsion after dilution in water.
ED	Electrochargeable liquid	Special liquid preparation for electrostatic (electrodynamic)spraying
EO	Emulsion. water in oil	A fluid. heterogeneous preparation consisting of a dispersion of fine globules of pesticide in water in a continuous organic liquid phase.
ES	Emulsion for seed treatment	A stable emulsion for application to the seed either directly or after dilution.

Code	***Description***	***Definition***
EW	Emulsion. Oil in water	A fluid, heterogeneous preparation consisting of a dispersion of fine globules of pesticide in an organic liquid in a continuous water phase.
FD	Smoke tin	Special form of smoke generator.
FG	Fine granule	A granule in the particle size range from 300 to 2500 :.
FK	Smoke candle	A smoke generator in the form of a candle.
FP	Smoke cartridge	Special form of smoke generator.
FR	Smoke rodlet	Special form of smoke generator.
FS	Flowable concentrate for seed treatment	A stable suspension for application to the seed either directly or seed treatment after dilution.
FT	Smoke tablet	Special form of smoke generator.
FU	Smoke generator	A combustible preparation generally solid, which upon ignition releases the active substances in the form of a smoke.
FW	Smoke pellet	Special form of smoke generator.
GA	Gas	A gas packed in pressure bottle or pressure tank.
GB	Granular bait	Special forms of bait.
GE	Gas generating product	A preparation which generates a gas by chemical reaction.
GG	Macrogranule	A granule in the particle size range from 2000 to 6000 :.
GP	Flo-dust	Very fine dustable powder for pneumatic application in glasshouses.
GR	Hot fogging concentrate	A free-flowing solid preparation of a defined granule size range ready for use.
GS	Cold fogging concentrate	Very viscous preparation based on oil or fat.
HN	Hot fogging concentrate	A preparation suitable for application by fogging equipment either directly or after dilution.
KN	Cold fogging concentrate	A preparation suitable for application by cold fogging equipment, either directly or after dilution.

Code	***Description***	***Definition***
LA	Lacquer	A solvent based film-forming preparation.
LS	Solution for seed treatment	A solution for application to the seed either directly or after dilution.
MG	Microgranule	A granule in the particle ske range from 100 to 600
OF	Oil miscible flowable (=oil active substances in a miscible suspension)	A stable suspension of concentrate fluid intended for dilution in an organic liquid before use.
OL	Oil miscible liquid	A liquid, homogenous preparation to be applied as a homogenous liquid after dilution in an organic liquid.
OP	Oil dispersible powder	A powder preparation to be applied as a suspension after dispersion in an organic liquid.
PA	Paste	A water based film forming preparation.
PB	Plate bait	Special forms of bait.
PC	Gel or paste concentrate	A solid preparation to be applied as a gel or a paste after dilution with water.
PR	Plant rodlet	A small rodlet, usually a few centimetres in length and a few millimetres in diameter containing active substance.
PS	Seed coated with a pesticide	Self defining.
RB	Bait (ready for use)	A preparation designed to attract and be eaten by the target species.
SB	Scrap bait	Special forms of bait.
SC	Suspension (= flowable concentrate)	A stable suspension of active substance(s) in a fluid intended for dilution with water before use
SE	Suspo-emulsion	A fluid. heterogeneous preparation consisting of a stable dispersion of active substance(s) in the form of solid particles.
SG	Water soluble granules	A preparation consisting of granules to be applied as a true solution of active substance after dissolution in water but many contain insoluble inert ingredients.

Code	***Description***	***Definition***
SL	Soluble concentrate	A liquid homogenous preparation to be applied as a true solution of active substance after dissolution in water but many contain insoluble inert ingredients.
SO	Spreading oil	A preparation designed to form a surface layer on application to water.
SP	Water soluble powder	A powder preparation to be applied as a true solution of the active substance after solution in water but which may contain insoluble inert ingredients.
SS	Water soluble powder for seed treatment	A powder to be dissolved in water before application to the seed.
SU	Ultra low volume (ULV) suspension	A suspension ready for use through ULV equipment.
TB	Tablet	Solid preparation in the form of small flat plates for dissolution in water.
TP	tracking powder	A rodenticidal contact preparation in powder form.
UL	Ultra low volume (ULV) liquid	A homogenous liquid ready for use through ULV equipment.
VP	Vapour releasing product	A preparation containing one or more volatile ingredients, the vapours of which are released into the air. Evaporation rate normally is controlled by using suitable preparations and/or dispensers.
WG	Water dispersible	A preparation granule consisting of granules to be applied after disintegration and dispersion in water.
WP	Wettable powder	A powder preparation to be applied as a suspension after dispersion in water.
WS	Water dispersible powder for slurry seed treatment	A powder to be dispersed at high concentration in water before application as a slurry to the seed.
XX	Others	

APPENDIX 2

FLUPYRADIFURONE

SPECIFIC TERMS AND ABBREVIATIONS

a	absolute organ weight
AAP	Algal Assay Procedure medium
aerob	aerobic test conditions
a-GT	alpha-glutamyl-transferase
ALAT	alanine aminotransferase
ALP	alkaline phosphatase
amu	atomic mass units
anaer	anaerobic test conditions
AR	applied radioactivity
ASAT	aspartate aminotransferase
ASTM	American Society for Testing and Materials
B	bacteria
biodeg	biodegradation
Chr. ab.	chromosome aberrations
CMC	carboxymethylcellulose
CoE	Council of Europe
crit.	criterion
d	decreased, but not statistically significantly
dc	statistically significantly decreased
DFI	Daily Food Intake
DMF	dimethylformamide
DO	Dissolved Oxygen
dr	dose-related
DWI	Daily Water Intake
E	total effect of mortality and fecundity/parasitic capacity, used in arthropod toxicity tests
E. coli	*Escherichia coli*
equal	used when the values given by the notifier are expressed in mg/kg bw/day.
equivalent	used when values given by the notifier are only expressed in mg/kg food, not in mg/kg bw/day, as species-dependent factor is used to translate these data to mg/kg bw/day.
ETE	Estimated Theoretical Exposure
GCP	good clinical practice
GIDH	glutamic-acid dehydrogenase

GOT	glutamic-oxalacetic transaminase
GPT	glutamic-pyruvic transaminase
HDL	high density lipoproteins
HPRT	hypoxanthine- guanine phosphoribosyl transferase
i	increased, but not statistically significantly
ic	statistically significantly increased
MC	moisture content in soil (v/v)
Mc	mammalian cells
MWHC	maximum water holding capacity (soils)
n/a	not applicable
n.d.	not detected
n.r.	not reported
ns	not significant
o.m.	organic matter
PEC	Predicted Environmental Concentration
PEG	polyethylene glycol
pF	moisture tension (soil) in [log $cm_{water\ column}$]
PIEC	Predicted Initial Environmental Concentration
pointmut.	pointmutations
r	relative organ weight
r.a.	radioactivity
res.	result
Ri	Reliability Index, referring to the intrinsic reliability of a test with respect to the quality of the study
S. typh.	*Salmonella typhimurium*
SPE	Solid Phase Extraction
Sub.	Substance
T	temperature
TWA	time weighted average

TWAEC	time weighted average environmental concentration
wat/sed	water/sediment systeem
w/w	weight per weight
-	negative
+	positive
-act.	without activation
+act.	with activation
%v/v	the percentage expressed by volume
%w/w	the percentage expressed by weight

APPENDIX 3

Flupyradifurone

LIST OF END-POINTS

Chapter 2.1 Identity, Physical and Chemical Properties, Details of Uses, Further Information

Active substance (ISO Common Name)	Flupyradifurone
Function (*e.g.* fungicide)	Insecticide

Rapporteur Member State	The Netherlands

Identity (Annex IIA, point 1)

Chemical name (IUPAC)	4-[(6-chloro-3-pyridylmethyl)(2,2-difluoroethyl)amino]furan-2(5H)-one
Chemical name (CA)	2(5H)-furanone, 4-[[(6-chloro-3-pyridinyl)methyl](2,2-difluoroethyl)amino]-
CIPAC No	not allocated
CAS No	951659-40-8
EEC No (EINECS or ELINCS)	not assigned
FAO Specification (including year of publication)	not applicable
Minimum purity of the active substance as manufactured (g/kg)	Min. 960 g/kg Flupyradifurone
Identity of relevant impurities (of toxicological, environmental and/or other significance) in the active substance as manufactured (g/kg)	Based on environmental and (eco)toxicological information, there are no relevant impurities.
Molecular formula	$C_{12}H_{11}ClF_2N_2O_2$
Molecular mass	288.68 g/mol
Structural formula	

Physical-chemical properties (Annex IIA, point 2)

Melting point (state purity)	69.0 °C (99.4%)
Boiling point (state purity)	No boiling point; decomposition occurred at 270°C (99.4%)
Temperature of decomposition	Decomposition occurred at the temperature range 270 – 355 °C (99.4%)
Appearance (state purity)	white powder with weak, not characteristic odour (99.4)
Relative density (state purity)	D_4^{20} = 1.43 (99.4%)
Surface tension	69.1 mN/m at 20°C (97.6%)

Vapour pressure (in Pa, state temperature)	9.1×10^{-7} Pa for 20 °C 1.7×10^{-6} Pa for 25 °C 2.6×10^{-5} Pa for 50 °C (extrapolated, 99.9%)
Henry's law constant (Pa m^3 mol^{-1})	8.2×10^{-8} Pa x m^3 x mol^{-1} at 20 °C
Solubility in water (g/L or mg/L, state pH and temperature)	pH 4 (buffer) 3.2 g/L at 20°C pH 9 (buffer) 3.0 g/L at 20°C In distilled water: pH 7 3.2 g/L at 20°C (99.4)
Solubility in organic solvents (in g/L or mg/L, state temperature)	[g/L at 20 °C] (99.4%) methanol > 250 n-heptane 0.0005 toluene 3.7 dichloromethane > 250 acetone > 250 ethylacetate > 250 dimethyl sulfoxide > 250
Partition coefficient (log P_{OW}, state pH and temperature)	At 25 °C, pH7 (99,4%) Pow log Pow 16 1.2
Hydrolytic stability (DT_{50}, state pH and temperature)	hydrolytically stable at ambient temperature in the range of pH 4 to pH9.
Dissociation constant	No dissociation occurs in aqueous solutions in the pH-range 1< pH <12
UV / VIS absorption (max.) (if absorption >290 nm state ε at wavelength)	UV/Vis-spectrum: MeOH

pH	λmax	ε
7.0	213	9615.06
	259	25800.49
2.0	214	9388.74

	<table><tr><td></td><td>259</td><td>26576.75</td></tr><tr><td>10.0</td><td>213</td><td>9996.41</td></tr><tr><td></td><td>259</td><td>25954.64</td></tr></table> ε: molar absorption coefficient, L/(molxcm) (99.4%)
Photostability (DT_{50}, aqueous, sunlight, state pH)	1st order half-life for photolytic degradation in sterile phosphate buffer (pH 7) was 13.8 experimental hrs.(99.3)
Quantum yield of direct phototransformation in water at Σ >290 nm	D = 0.000138 (99.4%)
Flammability	not highly flammable
Explosive properties	not explosive

Classification and proposed labelling (Annex IIA, point 10)

with regard to physical and chemical data	No classification is proposed

Remarks:
n) in case of group of crops the Codex classification should be used
o) Outdoor of field use (F), or glasshouse application (G)
p) e.g. biting and sucking in insects, soil born insects, foliar fungi
q) e.g. wettable powder (WP), emulsifiable concentration (EC), granule (GR)
r) Use CIPAC/FAO Codes where appropriate
s) All abbreviations used must be explained
t) Method, e.g. high volume spraying, low volume spraying, spreading, dusting, drench
u) Kind, e.g. overall, broadcast aerial spraying, row, individual plant, between the plants
v) g/l or g/L
w) Growth stage at last treatment
x) The minimum and maximum number of application possible under practical conditions of use must be provided
y) PHI - Pre Harvest Interval
z) Remarks may include: Extent of use/ economic importance/restrictions

Chapter 2.2 – Methods of Analysis

Analytical methods for the active substance (Annex IIA, point 4.1)

Technical as (principle of method)	HPLC-UV at 225 nm
Impurities in technical as (principle of method)	HPLC-UV at 210/256 nm
Plant protection product (principle of method)	HPLC-UV at 280 nm

Analytical methods for residues (Annex IIA, point 4.2)

Residue definitions for monitoring purposes

Food of plant origin		Flupyradifurone DFA, expressed as DFA ~~, sum of both expressed as flupyradifurone equivalents~~ separately
Food of animal origin		Flupyradifurone DFA, expressed as DFA ~~, sum of both expressed as flupyradifurone equivalents~~ separately
Soil		Flupyradifurone
Water	surface	Flupyradifurone, ~~DFA, 6-CNA~~
	drinking/ground	Flupyradifurone, ~~DFA, 6-CNA~~
Air		Flupyradifurone

Monitoring/ Enforcement methods

Analytical methods for residues (Annex IIA, point 4.2)

Food/feed of plant origin (principle of method and LOQ for methods for monitoring purposes)	HPLC-MS/MS method 01330 with acetonitrile/water (4/1, v/v) with 2.2 mL/L formic acid extraction. LOQ 0.01 mg/kg for flupyradifurone for lettuce, wheat, orange, rape seed potato, orange and wheat. LOQ 0.05 mg/kg for hop. LOQ 0.02 ~~1~~ mg/kg for DFA for lettuce, wheat, orange, rape seed potato, orange and wheat. LOQ 0.10 mg/kg for hop.
Food/feed of animal origin (principle of method and LOQ for methods for monitoring purposes)	HPLC-MS/MS acetonitrile/water (4/1, v/v), with the addition of n-heptane in the cases of fat and milk. LOQ 0.01 ~~2~~ mg/kg for flupyradifurone and LOQ 0.02 mg/kg for DFA in fat, liver, kindey, muscle, egg and milk.
Soil (principle of method and LOQ)	HPLC-MS/MS after extraction with acetonitrile. LOQ of 5µg/kg for BYI 02960
Water (principle of method and LOQ)	HPLC-MS/MS LOQ for BYI 02960 is 0.05 µg/L in drinking and surface water.
Air (principle of method and LOQ)	HPLC/MS-MS after extraction with acetonitrile.l LOQ for BYI 029607 µg /m^3
Body fluids and tissues (principle of method and LOQ)	No methods required.

Chapter 2.3 Impact on Human and Animal Health

Absorption, distribution, excretion and metabolism (toxicokinetics) (Annex IIA, point 5.1)

Rate and extent of oral absorption	The gastrointestinal absorption of radioactivity was high and fast, almost completely absorbed within 48h (75-90 % of administered radioactivity was detected in urine after oral administration and 76% was detected after i.v. administration). ~~It accounted for >80 % of the dose independent of the labelling position used.~~
Distribution	Maximum plasma concentration was reached approx. 1 h after administration of a single low dose (2 mg/kg bw) and 2-4 h after a single high dosage (200 mg/kg bw). Flupyradifurone is widely distributed with highest concentrations in liver and kidney. A fast decline was observed for all organs and tissues (<LOQ seven days after administration).
Potential for accumulation	No evidence for accumulation, supported by the low Pow of 1.2.
Rate and extent of excretion	Excretion was very fast, mainly renal and almost completed after 24 h (approx. 77-97% within 24h and 82-100% within 48h); 75-90% was extreted via

	urine within 48h and 7-26% was excreted via faeces.
Metabolism in animals	Moderately metabolised in the rat. The parent compound represented the predominant part of the radioactivity in urine. Main metabolited detected in urine (accounting for >10% of the dose administered) were BYI 02960-OH and BYI 02960-hippuric acid (only high dose male). Metabolites 6-CAN and DFA were detected in urine at levels >5% of the dose administered. Metabolic reactions: • hydroxylation followed by conjugation with glucuronic acid or sulfate, • cleavage of the difluoroethyl group forming BYI 02960-des-difluoroethyl, and difluoroacetic acid (DFA), • cleavage of the molecule at the pyridinylmethylene bridge forming 6-CNA, which was further conjugated with glycine to BYI 02960-hippuric acid and BYI 02960-difluoroethyl-amino-furanone. 6-CNA is considered a major metabolite in male rat but not in females.
Toxicologically relevant compounds (animals and plants)	Parent compound, DFA
Toxicologically relevant compounds (environment)	Parent compound, DFA

Acute toxicity (Annex IIA, point 5.2)

Rat LD_{50} oral	LD_{50} >300-2000 mg/kg ~~cut-off = 2000 mg/kg~~	H302
Rat LD_{50} dermal	LD_{50} > 2 000 mg/kg	
Rat LC_{50} inhalation	LC50 at 4 hours >4.7 mg/L (nose only) ~~> 4671 mg/m3~~	
Skin irritation	Non irritating	
Eye irritation	Slight redness of the conjunctivae, reversed within 48 hours	
Skin sensitisation	Not sensitising (LLNA)	

Short term toxicity (Annex IIA, point 5.3)

Target / critical effect	Liver effects in rodents and dogs, thyroid effects in rats, kidney effects in mice and dogs and degeneration of myofibers in skeletal muscles in dog	
Relevant oral NOAEL	6.0 ~~30.2~~ mg/kg bw/day (90-d rat study) 81 mg/kg bw/day (90-d mouse study) 12 mg/kg bw/day (90-d dog study)	

	7.8 mg/kg bw/day (1-y dog study)	
Relevant dermal NOAEL	500 mg/kg bw/day (28-d rat study)	
Relevant inhalation NOAEL	No data – not required	

Genotoxicity (Annex IIA, point 5.4)

	Flupyradifurone has no genotoxic potential	

Long term toxicity and carcinogenicity (Annex IIA, point 5.5)

Target/critical effect	Liver in both species, thyroid and lung in rats and kidney in mice	
Relevant NOAEL	15.8 mg/kg bw/day (2-year rat carcinogenicity) 43 mg/kg bw/day (2-year mouse carcinogenicity)	
Carcinogenicity	Not carcinogenic in both rats (> 80 mg/kg/day) and mice (>224 mg/kg/day)	

Reproductive toxicity (Annex IIA, point 5.6)

Reproduction toxicity

Reproduction target / critical effect	Parental: decreased body weight gain, increased liver and thyroid weight, centrilobular hypertrophy, decreased bw (gain) Reproductive: decreased estrous cycle number, litter size, number of implants. Offspring: meternal effects leading to effects on pup weight, physical development	
Relevant parental NOAEL	6.4 ~~7.7~~ ~~32~~ mg/kg bw/day	
Relevant reproductive NOAEL	34 mg/kg bw/day	
Relevant offspring NOAEL	34 mg/kg bw/day	

Developmental toxicity

Developmental target / critical effect	Maternal: decreased bw; increased liver weight. Developmental: short costal cartilage (rat only)	
Relevant maternal NOAEL	Rat: 30 mg/kg bw/day Rabbit: 40 mg/kg bw/day	
Relevant developmental NOAEL	Rat: 50 mg/kg bw/day Rabbit: 15 ~~40~~ mg/kg bw/day	

Neurotoxicity (Annex IIA, point 5.7)

Acute neurotoxicity	Piloerection and dilated pupils NOAEL: 35 mg/kg, (m/f)	

Repeated neurotoxicity	90d rat study: Systemic toxicity: body weight and food consumption effect, NOAEL: 29.4 mg/kg bw/d Neurotoxicity: No adverse effects, NO(A)EL: 143/173 mg/kg (m)	
Delayed neurotoxicity	No data available – not required	
Developmental neurotoxicity	Maternal: decreased body weight gain NOAEL: 42.4 mg/kg bw/day Offspring: decreased body weight gain NOAEL: 42.4 mg/kg bw/day Developmental neurotoxicity: slightly increased motor/locomotor activity and startle habituation. NOAEL: 42.4 mg/kg bw/day	

Other toxicological studies (Annex IIA, point 5.8)

Mechanism studies	**Biokinetic study in the plasma of rats following 7 day exposure through the diet:** Plasma concentrations were considered similar between the three times of blood collection for both sexes.
	28-day immunotoxicity study: Systemic NOAEL of 50 mg/kg bw/d Immunotoxic NOAEL of >230 mg/kg bw/d

Studies performed on metabolites or impurities	**Difluoroacetic acid** (DFA, BCS-AA56716, M44) - Ames test: negative - In vitro HPRG LGMA: negative - In vitro CA: Negative - Acute oral: 300 mg/kg <LD_{50} < 2000 mg/kg - 14-day dietary rat: NOAEL = 51 mg/kg bw/d - 90-day dietary rat: NOAEL = 12.7 mg/kg bw/d (m) **BYI 02960-difluoroethyl-amino-furanone** (BCS-CC98193, BYI 02960-DFEAF, M34) - Ames tes: negative - In vitro CA: positive in absence of metabolic activation - In vitro HPRT LGMA: negative - In vivo MNT: negative - In vivo UDS: negative - Acute oral: ≥ 2 000 mg/kg/day - 14-d dietary rat : NOAEL = 135 mg/d bw/d - 28-day dietary rat: NOAEL = 243 mg/kg bw/d **BYI 02960-CHMP** (6-chloropyridin-3-ylmethanol, IM-O, M21) - Ames test: negative - Acute oral: LD_{50} in females = 1483 mg/kg/day - 90-day dietary rat: NOAEL = 48.9 mg/kg bw/d **BYI 02960-6-CNA** (6-chloronicotinic acid, IC-0, M27) - Ames test: negative - Acute oral: LD_{50} ≥5000 mg/kg/day

Medical data (Annex IIA, point 5.9)

Limited as this is a new active ingredient

Summary (Annex IIA, point 5.10)	Value	Study	Safety factor
ADI	0.064 ~~0.08~~ ~~0.12~~ mg/kg bw/day	2-generation rat ~~90-day and 1-y dog study combined~~	100
AOEL	0.064 ~~0.08~~ ~~0.12~~ mg/kg bw/day	2-generation rat ~~90-day and 1-y dog study combined~~	100 *
ARfD	0.15 ~~0.35~~ mg/kg bw	Rabbit developmental ~~acute neurotox study~~	100

*oral absorption is >80%, correction for oral absorption not necessary.

Dermal absorption (Annex IIIA, point 7.3)

BYI 02960 200 SL*	Based on human in vitro absorption values corrected for the large variation: 0.4% at 200 g/L 3 % at 0.625 g/L 8 % at 0.1 g/L 17% at 0.045 g/L (calculated *pro rata*)

~~* A *pro rata* corrected dermal absorption of 17% for the spray dilution is used in the exposure scenarios based on a dilution of 0.045 g/L~~.

Exposure scenarios (Annex IIIA, point 7.2)

		without PPE	with PPE
Operator – use on hop ((% AOEL) Mechanical upward spraying, field	UK-75th	42.9	29.0
	DE-GM	53.1	49.7
Operator – use on lettuce (% AOEL) Mechanical downward spraying, field	UK-75th	50.5	7.7
	DE-GM	20.0	15.9
Operator – use on lettuce (% AOEL) Manual downward spraying, field	UK-75th	119.3	21.8
Operator – use on lettuce (% AOEL) Manual downward spraying, (indoor)	Dutch greenhouse model	97.7	12.3
Workers	exposure up to 46.1 % of the AOEL, without PPE (EUROPOEM II)		
Bystanders	exposure up to 5.8 % of the AOEL (EUROPOEM II)		
Resident	Exposure up to 0.58 % of the AEL (German model for the child)		

Classification and proposed labelling with regard to toxicological data (Annex IIA, point 10)

Substance classified (BYI 02960)	-

Chapter 2.4 Residues

Metabolism in plants (Annex IIA, point 6.1 and 6.7, Annex IIIA, point 8.1 and 8.6)

Plant groups covered	Foliar treatment: fruit (apple), pulses/oilseeds (cotton), cereals (rice) Soil treatment: fruit (tomato), root and tuber vegetables (potato), seed treatment: root and tuber vegetables (potato), cereals (rice)
Rotational crops	Turnips, wheat, Swiss chard
Metabolism in rotational crops similar to metabolism in primary crops?	Yes
Processed commodities	Hydrolysis (pasteurisation, baking, brewing, boiling, sterilisation)
Residue pattern in processed commodities similar to residue pattern in raw commodities?	Parent flupyradifurone is stable, no information on major metabolites DFA and DFEAF
Plant residue definition for monitoring	Flupyradifurone DFA, expressed as DFA ~~, sum of both expressed as flupyradifurone equivalents~~ separately
Plant residue definition for risk assessment	The sum of parent compound flupyradifurone and its metabolites DFA ~~and difluoroethyl-amino-furanone (DFEAF)~~, expressed in flupyradifurone equivalents.
Conversion factor (monitoring to risk assessment)	1

Metabolism in livestock (Annex IIA, point 6.2 and 6.7, Annex IIIA, point 8.1 and 8.6)

Animals covered	Laying hen, lactating goat
Time needed to reach a plateau concentration in milk and eggs	Eggs: 6 days, confirmed by feeding study Milk: 9 days, confirmed by cattle feeding study
Animal residue definition for monitoring	Flupyradifurone DFA, expressed as DFA ~~, sum of both expressed as flupyradifurone equivalents~~ separately
Animal residue definition for risk assessment	The sum of flupyradifurone and metabolite DFA, expressed in flupyradifurone equivalents.
Conversion factor (monitoring to risk assessment)	Not applicable
Metabolism in rat and ruminant similar (yes/no)	yes
Fat soluble residue: (yes/no)	no

Residues in succeeding crops (Annex IIA, point 6.6, Annex IIIA, point 8.5)

Residue trials on succeeding cereals, root crops and leafy crops were conducted in NEU and SEU at a application rate of 200 g as/ha (on soil or lettuce) in three rotations with plant back intervals (PBI) of: 25-33d (1st rotation), 61-145d (2nd rotation) and 266-329d 93rd rotation). For root crops and leafy crops, samples were taken at early harvest (eh) and normal harvest (nh) growth stages. Quantifiable residues were measured in all rotations, median values and range is reported. Residues in first rotation crops were always highest.

1st rotation:

carrot/turnip root (eh): 0.06 mg/kg (0.05-0.14)

carrot/turnip root (nh): 0.08 mg/kg (0.05-0.12)

Lettuce (eh): 0.08 mg/kg (0.06-0.21)

Lettuce (nh): 0.07 mg/kg (<0.04-0.16)

Barley green forage: 0.10 mg/kg (0.05-0.41)

Barley straw: 0.12 mg/kg (<0.07-0.39)

Barley grain: 0.35 mg/kg (0.11-0.65)

2nd rotation:

carrot/turnip root (eh): 0.04 mg/kg (<0.04-0.07)

carrot/turnip root (nh): 0.05 mg/kg (<0.04-0.06)

Lettuce (eh): 0.04 mg/kg (<0.04-0.12)

Lettuce (nh): 0.04 mg/kg (<0.04-0.11)

Barley green forage: 0.05 mg/kg (0.05-0.13)

Barley straw: <0.07 mg/kg (<0.07-0.12)

Barley grain: 0.12 mg/kg (0.06-0.28)

3rd rotation:

carrot/turnip root (eh): 0.05 mg/kg (<0.04-0.06)

carrot/turnip root (nh): 0.05 mg/kg (<0.04-0.06)

Lettuce (eh): <0.04 mg/kg (<0.04-0.10)

Lettuce (nh): <0.04 mg/kg (<0.04-0.07)

Barley green forage: 0.04 mg/kg (<0.04-0.19)

Barley straw: <0.07 mg/kg (<0.07-0.19)

Barley grain: 0.12 mg/kg (0.08-0.39)

Field rotational crop trials at 2x 125 g/ha in various crops after short plant back intervals (30d):

Potatoes: 0.13 mg/kg (0.05-0.27)

Leek: 0.09 mg/kg (0.04-0.25)

Cucumber: 0.32 mg/kg (0.07-0.43)

Onion: 0.09 mg/kg (<0.04-0.18)
Bean (legume): 0.50 mg/kg (0.28-1.1)
Field peas (pulses): 1.6 mg/kg (0.67-2.3)
winter rape: 0.10 mg/kg (0.07-0.17)
Cereals: 0.35 mg/kg (0.11-0.65)

Stability of residues (Annex IIA, point 6 introduction, Annex IIIA, point 8 Introduction)

Flupyradifurone DFEAF, and DFA are stable in orange fruit (high acid content), spinach leaves and tomato fruit (high water content), wheat grain (high starch content), bean seed (high protein content), coffee bean (specific matrix), soybean seed (high oil content), and sugar cane (high water content) for at least 18 months when stored frozen (≤-20°C).
DFA is stable in animal fat, kidney, liver, and muscle for at least 43 days, when stored frozen (≤-20°C).

Residues from livestock feeding studies (Annex IIA, point 6.4, Annex IIIA, point 8.3)

	Ruminant:	Poultry:	Pig:
	Conditions of requirement of feeding studies		
Expected intakes by livestock ≥ 0.1 mg/kg diet (dry weight basis) (yes/no - If yes, specify the level)	Yes	Yes	Yes
Potential for accumulation (yes/no):	No	No	See ruminant
Metabolism studies indicate potential level of residues ≥ 0.01 mg/kg in edible tissues (yes/no)	Yes	Yes	See ruminant
	Feeding studies (Specify the feeding rate in cattle and poultry studies considered as relevant) Dairy cattle: 4.8 mg flupyradifurone/kg dry feed (1.6 ~~1.8N~~ ~~2N~~) Laying hens: 1.5 mg flupyradifurone /kg dry feed (1.2N) Residue levels in matrices : Mean (max) mg/kg*

Consumer risk assessment (Annex IIA, point 6.9, Annex IIIA, point 8.8)

ADI	0.064 ~~0.08~~ ~~0.12~~ mg/kg bw/d
TMDI (% ADI) according to WHO European diet	15.1 ~~47.3~~ ~~75.6~~% WHO Cluster diet B
TMDI (% ADI) according to national diet	12.1% UK toddler ~~31.6% Danish child~~ ~~60.1% German child~~
IEDI (WHO European Diet) (% ADI)	Not required
NEDI (specify diet) (% ADI)	Not required
Factors included in IEDI and NEDI	Not applicable
ARfD	0.15 ~~0.35~~ mg/kg bw
IESTI (% ARfD)	82.3% ~~161.4%~~ Lettuce, German child ~~524.6% Dutch child (celery, import tolerance, MRL application)~~
NESTI (% ARfD) according to national (to be specified) large portion consumption data	See IESTI ~~81.8 69.2% German child (lettuce)~~ ~~83.4% UK infant (oranges, import tolerance, MRL application)~~
Factors included in IESTI and NESTI	Proposed MRLs, HR and processing factors for lettuce inner heads, beer (hops) and melon peel/pulp distribution

Processing factors (Annex IIA, point 6.5, Annex IIIA, point 8.4)

Crop/ process/ processed product	Number of studies (valid studies)	Processing factors Transfer factor (mean)	Amount transferred (%) (Optional)
Lettuce outer leaves	4	1.8	
Lettuce inner head parts	4	0.72 ~~0.73~~	
Lettuce inner leaves	4	0.87 ~~0.76~~	
Lettuce washed inner leaves	4	0.65 ~~0.67~~	
Lettuce washing water	4	0.02 ~~0.07~~	
Hops draff	2	<0.11	
Brewer's yeast	2	<0.11	
Beer	2	0.02 ~~0.01~~	

Processing factors for DFA were all <0.2.

Proposed MRLs (Annex IIA, point 6.7, Annex IIIA, point 8.6)

Crop	MRL proposal (mg/kg)	
	Flupyradifurone	**DFA, expressed as DFA**
Lettuce	9	0.1
Hops	4	0.4
Rotational root and tuber vegetables	0.01	0.09
Rotational stem vegetables	0.01	0.08
Rotational bulb vegetables	0.01	0.06
Rotational fruiting vegetables	0.01	0.15
Rotational legume vegetables	0.01	0.4
Rotational leafy vegetables	0.08	0.04
Rotational cereals and sweet corn	0.01	0.3
Rotational pulses	0.01	0.8
Rotational oilseeds	0.01	0.05
eggs	0.01*	0.03
poultry meat (muscle)	0.01*	0.05
poultry fat	0.01*	0.03
poultry liver/offal	0.01*	0.1
milk	0.01*	0.03
Ruminant, pig and horse meat (muscle)	0.01*	0.1
Ruminant, pig and horse fat	0.01*	0.1
Ruminant, pig and horse liver	0.01*	0.1
Ruminant, pig and horse kidney	0.01*	0.15
other ruminant, horse and pig offal	0.01*	0.15

Parallel to the peer review of flupyradifurone under Reg (EC) 1107/2009, an application for the setting of MRLs from additional uses in the EU ~~and import tolerances~~ is ongoing.

Chapter 2.5 Fate and behaviour

Route of degradation (aerobic) in soil (Annex IIA, point 7.1.1.1.1)

Mineralization after 100 days *	29.4-58.6% (n=4, PYM-^{14}C BYI 02960) 20.2-57.4% (n=3, PYR-^{14}C BYI 02960) 12.3-38.9% (n=6, FUR-^{14}C BYI 02960) 25.9-42.3% (n=3, ETH-^{14}C BYI 02960)
Non-extractable residues after 100 days *	12.5-16.8% (n=4, PYM-^{14}C BYI 02960) 11.3-25.5% (n=3, PYR-^{14}C BYI 02960) 16.4-34.1% (n=6, FUR-^{14}C BYI 02960) 14.3-17.9% (n=3, ETH-^{14}C BYI 02960)
Metabolites requiring further consideration - name and/or code, % of applied (range and maximum)	difluoroacetic acid (DFA, max. 33.9%) 6-chloronicotinic acid (6-CNA, max. 17.1%)

PYM (= pyrindinyl-methyl-^{14}C-label), PYR (= pyridine-2,6-^{14}C-label), FUR (= furanone-4-^{14}C-label) and ETH (= ethyl-1-^{14}C-label)
* at the end of the experiment at 120 days; n = number of soils tested

Route of degradation in soil - Supplemental studies (Annex IIA, point 7.1.1.1.2)

Anaerobic degradation

Mineralization after 100 days*	6.0-26.6% (n=3, PYR-^{14}C BYI 02960) 15.9% (n=1, FUR-^{14}C BYI 02960) 6.9% (n=1, ETH-^{14}C BYI 02960) Formed at the aerobic phase
Non-extractable residues after 100 days*	12.9-17.2% (n=3, PYR-^{14}C BYI 02960) 30.1% (n=1, FUR-^{14}C BYI 02960) 15.2% (n=1, ETH-^{14}C BYI 02960)
Metabolites that may require further consideration for risk assessment - name and/or code, % of applied (range and maximum)	DFA (max. 26.2%; mainly during aerobic phase) 6-CNA (max. 14.2%; mainly during aerobic phase)

* duration experiment 120 days, value at the end of the experiment; n = number of soils

Soil photolysis

Metabolites that may require further consideration for risk assessment - name and/or code, % of applied (range and maximum)	no major metabolites	
	mineralization 0.1-2.2%	8 d cont. irradiation
	bound residues0.8-0.9%	8 d cont. irradiation
	DT_{50} (SFO) 99.6-109.3 d	8 d cont. irradiation
	419.2->1000 d	8 d dark control

FOCUS STEP 4
Hops, 1 x 150 g/ha

Buffer Width & Type	FOCUS Scenario	PEC_{sw} [µg/L] Drift Reduction				PEC_{sed} [µg/kg] Drift Reduction			
		25%	50%	75%	90%	25%	50%	75%	90%
0m (drift)	R1 (pond, 1st)	0.296	0.197	0.099	0.039	0.607	0.415	0.218	0.094
	R1 (stream, 1st)	4.149	2.766	1.383	0.553	0.273	0.184	0.093	0.072
5m (drift)	R1 (pond, 1st)	0.445	0.223	0.111	0.045	0.891	0.465	0.244	0.105
	R1 (stream, 1st)	4.515	2.258	1.129	0.452	0.297	0.151	0.076	0.071
10m (drift & run-off)	R1 (pond, 1st)	0.253	0.126	0.063	0.025	0.522	0.273	0.142	0.061
	R1 (stream, 1st)	2.354	1.177	0.589	0.235*	0.157	0.080	0.04	0.031
15m (drift & run-off)	R1 (pond, 1st)	0.141	0.071	0.035	0.014*	0.302	0.158	0.083	0.036
	R1 (stream, 1st)	1.554	0.777	0.388	0.155*	0.104	0.053	0.032	0.03
20m (drift & run-off)	R1 (pond, 1st)	0.078	0.039	0.02*	0.008*	0.174	0.091	0.048	0.021
	R1 (stream, 1st)	0.708	0.354	0.177*	0.071*	0.048	0.025	0.017	0.016

The mitigation from 10 m onwards includes spray drift and concurrent run-off buffer. However, as can be seen from the linear decrease of PEC_{sw} values with increasing drift reduction, the PEC_{sw} is always drift dominated and the run-off buffer does not drive the PEC_{sw}. * reduction of the overall drift percentage is >95%, compared to STEP3, in case drift leads to PECsw max.

(hops and lettuce field) 10 (lettuce, glass) Time of application: BBCH 31-75 (hops annual and biennial) BBCH 41-49 (lettuce annual) BBCH 12-49 (lettuce biennual) (month or season) BBCH 12-49 (lettuce, glasshouse) Plant interception (%): 60 (hops annual and biennial) 70 (lettuce annual) 25 (lettuce biennual)) 25 (lettuce, glasshouse)

* The sum of formation fractions of both metabolites is > 1. In order to run the modeling with PELMO, the molar mass of 6-CNA was set to 451 g/mol, resulting from $M_{auxiliary}$ (6-CNA) = M (6-CNA) × 0.478 / (1-0.833) = 451 g/mol
** Kinetic formation fraction used for PEARL, values used for PELMO see DAR;
Additional higher Tier PECgw calculations with time dependent sorption are presented in the DAR.
~~*** Glass house application worst case for groundwater, no field applications included in LoEP~~
~~**** Data provided to justify that the plant uptake factor for the active substance and metabolites is 0.5~~

Fate and behaviour in air (Annex IIA, point 7.2.2, Annex III, point 9.3)

Direct photolysis in air	Not studied - no data requested
Quantum yield of direct phototransformation	1.38 x 10^{-4} mol/Einstein in water
Photochemical oxidative degradation in air	DT_{50} of 4.4 hours (0.18 d) derived by the Atkinson model (AOPWIN version 1.92a). OH (12 h) concentration assumed = 1.5 x 10^{-6} OH/cm^3
Volatilisation	From plant surfaces (BBA guideline): no data Vapour pressure: 9.1 x 10^{-7} Pa at 20°C
	From soil surfaces (BBA guideline): no data
Metabolites	No data

PEC (air)

Method of calculation	Expert judgement, based on Vapour pressure 9.1 x 10^{-7} Pa at 20°C,

	Henry's Law Constant 4.13 x 10^{-7} Pa m^3 mol^{-1} Atmospheric half life 4.4 – 13.1 hours residues in air are expected to be negligible.

$PEC_{(a)}$

Maximum concentration	No data provided - none requested

Residues requiring further assessment

Environmental occurring metabolite requiring further assessment by other disciplines (toxicology and ecotoxicology).	Soil:	BYI 02960, 6-CNA, DFA
	Surface Water:	BYI 02960, 6-CNA, DFA, BYI 02960-succinamide, BYI 02960-azabicyclosuccinmaide
	Sediment:	BYI 02960, 6-CNA, DFA
	Ground water:	BYI 02960, 6-CNA, DFA
	Air:	BYI 02960

Monitoring data, if available (Annex IIA, point 7.4)

Soil (indicate location and type of study)	New active substance, not applicable
Surface water (indicate location and type of study)	New active substance, not applicable
Ground water (indicate location and type of study)	New active substance, not applicable
Air (indicate location and type of study)	New active substance, not applicable

Points pertinent to the classification and proposed labelling with regard to fate and behaviour data

Not readily biodegradable; candidate for R53

Chapter 2.6 Ecotoxicology

Effects on terrestrial vertebrates (Annex IIA, point 8.1, Annex IIIA, points 10.1 and 10.3)

6-chloro-picolylalcohol	>10000	>0.413

* These studies were performed in 2012/2013. Some uncertainties were noted during peer review arising from the lack of toxic standard, the lack of information on the history of the used bees, the lack of experience of conducting these kind of tests and the lack of experience for the interpretation of these tests. However, it is noted that currently no harmonised guideline is available, nor an agreed reference performance for any potential toxic standard. The studies were used in the risk assessment as additional information only .

Chronic toxicity studies on honeybee larvae*		
Test substance	NOEC µg/diet	NOEC µg/larvae
a.s.	≥ 10000 (nominal)	1.32 µg a.s./larvae (nominal) (accumulated exposure on day +4, +5 and +6 after grafting of the larvae)

* This study was performed in 2010. Some uncertainties were noted during peer review arising the lack of experience of conducting these kind of tests and the lack of experience for the interpretation of these tests. The study was used in the risk assessment as additional information only .

Acute toxicity studies on adult bumblebees	
Test substance	Acute contact toxicity (LD_{50} µg/bee)
Flupyradifurone SL 200 G	>100 (a.s.)

[1] BYI 02960 SL 200 G = BYI 02960 SL 200 g/L = Flupyradifurone SL 200 G = Sivanto

Field or semi-field tests
Five acceptable semi-field (gauze tunnel) studies are available, where BYI 02960 formulations were applied to Phacelia tanacetifolia with honey bees actively foraging on the crop (i.e. during bee flight) with different application regimes (ranging from 1x 75 g a.s. foliar spray to 1x 300 g a.s./ha soil application + 2x 200 g a.s./ha. Furthermore, two field studies are available in oil seed rape where BYI 02960 formulations were applied with honey bees actively foraging on the crop (i.e. during bee flight) at 2x 200 g a.s./ha with

preceding 1x 300 g a.s./ha soil application and 10 g a.s./kg seed seed treatment.

In the semi-field and field studies, the only clearly treatment-related effects seen were short-term reduced flight intensity (one to at most seven days after application) and behaviour anomalies in some bees (one day after application) after the foliar application during full flowering. Furthermore some slight, transient, potential effects were observed on other parameters. However this did not lead to reduced colony performance or survival.

Also, a large residue package is available with a.o. residues measured in pollen and nectar taken both from foragers and from hives, from studies in Phacelia and oil seed rape.

Lastly, a long-term feeding study was submitted in which colonies were forced to feed on up to 10 mg/kg diet for seven weeks. This did not lead to collapse of the colonies, including overwintering.

The overall data package shows that the spraying of 2x 200 g a.s./ha on a bee-attractive crop during full flowering and active foraging of honey bees may have caused some slight transient treatment related effects, but does not result in adverse acute or long-term (including overwintering) effects on honey bee colonies. Therefore, the risk to honey bees from application on the non-bee attractive crops hops and lettuce is clearly covered.

Hazard quotients for honey bees (Annex IIIA, point 10.4)

Application rate: 0.150 kg a.s./ha (hops, worst case for lettuce)

Field or semi-field tests
Two NTA field studies were performed with BYI 02960 SL 200 (200 g flupyradifurone/L) on grassland to similate an off-crop community. Soil-surface and plant-dwelling arthropod communities were sampled just before application and 1, 2, 4 and 8 weeks after application. Netherlands: NTA full fauna off-crop field study. Spray application rates: 1x 0.51, 1.7, 5.1, 21 g a.i./ha Community level NOER = 21 g a.i./ha Population level NOER = 5.1 g a.i./ha Population level NOEAER = 21 g a.i./ha, effect class 2 (two taxa adversely affected on one sampling moment shortly after application in the highest treatment rate, but both populations recovered withtin the next sampling moment one or two weeks later). SW France: NTA full fauna off-crop field study. Spray application rates: 1x 0.51, 1.7, 5.1, 21 g a.i./ha Community level NOER = 21 g a.i./ha Population level NOER = 1.7 g a.i./ha Population level NOEAER = 5.1 g a.i./ha effect class 2 (two taxa adversely affected on one sampling moment, recovery at next sampling moment). Population level NOEAER = 21 g a.i./ha effect class 3a (three taxa adversely affected, of which one on two sampling moments; effects no longer statistically significant on the last two sampling dates) NOER: No Observed Effect Rate NOEAER: No Observed Ecologically Adverse Effect Rate The underlined value is used in the off-field risk assessment (without SF)

LEVEL 3

Flupyradifurone

PROPOSAL FOR THE DECISION

3 Proposed decision with respect to the application for approval of the active substance in Annex I

3.1 Background to the proposed decision

The representative formulation for flupyradifurone is Sivanto SL200. Sivanto SL200 is a soluble concentrate (SL) containing 200 grams per litre (g/L) of flupyradifurone and is proposed as an insecticide in agriculture to control mainly sucking insects after foliar spray application on various crops.

The submitted gap is adequate, in that it concerns two very different crops that likely represent worst case situations for the evaluation of other aspects. The aim of the efficacy evaluation for approval of the active substance is to establish if the GAP is realistic.
The claimed dose rates for hops, 0.75 L/ha (0.150 g a.s./ha) and for lettuce grown in the field, 0.125 g a.s./ha were found to be the minimum effective dose rates. No trials were submitted for lettuce grown in the greenhouse, and therefore the dose rate for this use has not been proven to be the correct dose rate.
While no large differences in dose rate are expected between the indoor and outdoor use in lettuce, the dose rate could be different because of differences in pest pressure, or higher sensitivity to phytotoxicity because of different growing conditions.

For approval of a new active substance data on efficacy is required on one or more representative uses on a widely grown crop in each zone of at least one plant protection product containing the active substance, showing adequate efficacy. Without the greenhouse use for lettuce, the submitted data for approval of the active substance can still be considered sufficient for efficacy.

The representative formulation caused no unacceptable phytotoxic effects.

The physical and chemical properties of both the active substance Flupyradifurone and the representative formulation Sivanto SL200 are sufficiently described.
The provided analytical methods for the determination of the active substance and/or impurities in technical material and in the plant protection product are acceptable. The provided analytical methods for residue analysis in plants and plant products, foodstuffs and feeding stuffs, soil, water and air are acceptable.

For flupyradifurone, an Acceptable Daily Intake (ADI) of 0.08 ~~0.12~~ mg/kg bw/day, an ARfD of 0.15 ~~0.35~~ mg/kg bw and and AOEL of 0.08 ~~0.12~~ mgkg bw/d can be established.
Safe uses were identified for operators without PPE using the DE-GM and UK-POEM model (outdoors), manual spraying using UK-POEM model (outdoors) and the Dutch-90th greenhouse model

(indoors). Safe uses were also identified for workers (without PPE) and bystanders using the EUROPOEM II 2002 model (90th percentile) and residents (Martin *et al*.).

Residue levels and metabolic pathway in crops treated with flupyradifurone according to the intended use and the intended use in the MRL dossier are sufficiently described. Residues are expected in rotational crops and livestock. MRLs are proposed for rotational crops and products of animal origin. Based on the evaluation of the intended use for approval and intended use in the MRL dossier, the use of flupyradifurone is not considered to result in an unacceptable risk for the consumer due to exposure to residues in food products.

The fate and behaviour of the active substance flupyradifurone ~~is being~~ has been assessed for soil, groundwater, suface water and sediment and air. The active substance is not persistent in soil: geometric mean non-normalised laboratory DT_{50} trigger value of 73.2 days ~~and~~. Two major metabolites 6-CNA and DFA are formed in laboratory soil degradation studies (max 17.1% and 33.9% respectively). ~~The obtained PEC_{soils} are used in the ecotoxicological assessment.~~ The active substance flupyradifurone has the potential to leach to the groundwater. The groundwater triggers were passed with higher tier approaches, such as kinetic sorption and DFOP approaches. The leaching of the active substance flupyradifurone is for some scenarios critical and ~~in many scenarios~~ shows exceedings of the threshlod values in many scenarios. DFA, one of the major metabolites, shows a potential for leaching to the groundwater. DFA is declared a non relevant metabolite for groundwater assessment. The other metabolite 6-CNA does not show a potential ~~for leach~~ to leach to the groundwater. The active substance flupyradifurone is persistent in water sediment systems (geometric mean DT_{50} value of 228 days). ~~The obtained PECsw/sed are used in the ecotoxicolgical assessment.~~ Flupyradifurone is readily degraded in air.

For the proposed uses in hops (1-150 g a.s./ha) and lettuce (1x125 g a.s./ha) acceptable risk is expected for birds, ~~wild mammals,~~ bees, earthworms, other soil macro-organisms, organic matter breakdown, soil micro-organisms, terrestrial non-target plants and activated sludge. For mammals, the acute risk for both uses and the long-term risk for the use in hops are acceptable, but a long-term risk for small herbivorous mammals cannot be excluded for the use in lettuce.
Acceptable risk to aquatic organisms is expected provided that mitigation options are used ~~(for the use in hops up to 90% drift reducing nozzles; for the use in lettuce up to 20m VFS and 90% drift reducing nozzles)~~. For hops, acceptable risk can be reached in the one relevant complete scenario with different combinations of buffer zones and spray drift reduction. For the biennial use in lettuce, an acceptable use can be shown for three of the seven complete FOCUS scenarios considering different mitigation options (up to 20m VFS). For the annual use in lettuce, an acceptable use can be shown for two of the seven complete FOCUS scenarios considering different mitigation options (up to 20m VFS).

Acceptable risk to non-target arthropods is expected provided that for both uses , risk mitigation is used (in hops e.g. a buffer zone of ~~2~~30 m, in lettuce e.g. a buffer zone of 5 m). ~~Risk mitigation for non-target arthropods is not necessary for the use in lettuce.~~

The active substance does not comply with the criteria for POP, PBT, vPvB.

3.2 Proposed decision concerning the approval of the active substance according to Regulation (EC) No 1107/2009

It is proposed to approve flupyradifurone according to Regulation (EC) No 1107/2009.

3.3 Rational for the conditions and restrictions to be associated with a proposed approval of the active substance according to Regulation (EC) No 1107/2009

No conditions or restrictions are to be associated with the proposed approval of flupyradifurone.

LEVEL 4

Flupyradifurone

DEMAND FOR FURTHER INFORMATION

4 Further information to permit a decision to be made, or to support a review of the conditions and restrictions associated with the proposed inclusion in Annex I

4.1 Identity of the active substance

Please refer to the confidential annex C (volume 4).

4.2 Physical and chemical properties of the active substance

No additional data required.

4.3 Data on application and further information

No additional data required.

4.4 Classification, packaging and labelling

No additional data required.

4.5 Methods of analysis

No additional data required.

4.6 Toxicology and metabolism

No additional data required.

4.7 Residues

~~No additional data required.~~ Additional data required to address the expected residue levels of DFA in products of animal origin resulting from exposure to DFA in feed and additional data to address the magnitude of residue in rotational crops conducted at realistic-worst-case plant back intervals with regard to the following crop selected, and providing in addition soil analyses.

4.8 Fate and behaviour

No additional data required.

4.9 Ecotoxicology

~~No additional data required.~~ Additional data required to address the long-term risk to small herbivorous mammals from the use in lettuce.

4.10 Efficacy

No additional data required.

European Commission

Flupyradifurone

Section A.4 Proposals for classification and labelling (Annex IIA 10; Annex IIIA 12.3 and 12.4)

The proposed classification and labelling for the active substance Flupyradifurone and the formulations is based on the physico-chemical, toxicological and ecotoxicological evaluation as presented in section B.2, B.6 and B.9 respectively.

Section A.5 Methods of analysis (Annex IIA 4; Annex IIIA 5)

Flupyradifurone

VOLUME 3

ANNEX B

B.1 Identity
B.2 Physical and chemical properties
B.3 Data on application and further information
B.4 Proposals for classification and labelling
B.5 Methods of analysis

Rapporteur Member State: The Netherlands

November 2014
~~January 2014~~

Draft Assessment Report and Proposed Decision of the Netherlands prepared in the context of the possible approval of flupyradifurone under Regulation (EC) 1107/2009

Contents

B.1	**Identity**	**1**
B.1.1	Identity of the active substance (Annex IIA 1 and 3.1)	1
B.1.2	Identity of the plant protection product (annex IIIA 1)	1
B.1.3	References relied on	1
B.2	**Physical and chemical properties**	**2**
B.2.1	Physical and chemical properties of the active substance (Annex IIA 2) and metabolites	2
B.2.2	Physical, chemical and technical properties of the plant protection products (Annex IIIA 2)	2
B.2.3	Summary of physical and chemical properties	22
B.2.4	References relied on	23
B.3	**Data on application and further information**	**38**
B.3.1	Data on application relevant to the active substance (Annex IIA 3.1 to 3.6)	38
B.3.2	Data on application relevant to the plant protection product (Annex IIIA 3)	39
B.3.3	Summary of data on application	40
B.3.4	Further information on the active substance (Annex IIA 3.7 to 3.9)	42
B.3.5	Further information on the plant protection product (Annex IIIA 4)	46
B.3.6	References relied on	55
B.4	**Proposals for classification and labeling**	**58**
B.4.1	Proposals for the classification and labelling of the active substance (Annex IIA 10)	58
B.4.2	Proposals for the classification and labelling of preparations (Annex IIIA 12.3 and 12.4)	59
B.4.3	References relied on	60
B.5	**Methods of analysis**	**61**
B.5.1	Analytical methods for formulation analysis (Annex IIA 4.1; Annex IIIA 5.1)	61
B.5.2	Analytical methods (residue) for plants, plant products, foodstuffs of plant and animal origin, feedingstuffs (Annex IIA 4.2.1; Annex IIIA 5.2)	64
B.5.3	Analytical methods (residue) soil, water, air (Annex IIA 4.2.2 to 4.2.4; Annex IIIA 5.2)	78
B.5.4	Analytical methods (residue) for body fluids and tissues (Annex IIA 4.2.5; Annex IIIA 5.2)	85
B.5.5	Evaluation and assessment	85
B.5.6	References relied on	86

B.1 Identity

B.1.1 Identity of active substance (Annex IIA 1 and 3.1)

All points of Annex IIA, Section I are addressed in Volume 1, Level 1.

B.1.2 Identity of the plant protection product (Annex IIIA 1)

All points of Annex IIIA, Section 1 are addressed in Volume 1, Level 1.

B.1.3 References relied on

No specific references.

B.2 Physical and chemical properties

B.2.1 Physical and chemical properties of the active substance (Annex IIA 2)

See Table B.2.1-1.

Furthermore, some physical and chemical properties are presented for metabolites: BCS-CC98193 (BYI 02960-DFEAF), BCS-CR74729 (BYI 02960-succinamide), BCS-CU93236, BCS-AA56716 (Difluoroacetic acid), IC-0 (6-CNA).

B.2.2 Physical, chemical and technical properties of the plant protection product (Annex IIIA 2)

See Table B.2.2.

Table B.2.1-1 **Summary of the physical and chemical properties of the active substance** (studies were conducted under GLP and completed to an acceptable standard and results were considered to be valid unless specified otherwise).

section (Annex point)	study	purity	method	results	comment	reference
B.2.1.1 (IIA 2.1.1)	Melting point	99.4% 97.6%	EC A.1, OECD 102 GLP:Y	The melting point of Flupyradifurone, pure at atmospheric pressure is 69.0 °C. The melting point of Flupyradifurone, technical at atmospheric pressure is 67.1 °C.	Acceptable	Smeykal, H.; 2010 Smeykal, H.; 2011
B.2.1.2 (IIA 2.1.2)	Boiling point	99.4% 97.6%	EC A.2, OECD 103 GLP:Y	The test item had no boiling point at atmospheric conditions; the test item decomposed first at a temperature of 270 °C The test item had no boiling point; the test item decomposes first starting at a temperature of 245 °C	Acceptable	Smeykal, H.; 2010 Smeykal, H.; 2011
B.2.1.3 (IIA 2.1.3)	Thermal stability	99.4% 97.6%	EC A.2, OECD 103 GLP:Y	The test item showed an exothermal decomposition in the temperature range 270 – 355 °C with a mean decomposition energy of 895 J/g. The test item Flupyradifurone (BYI 02960), technical substance, showed an exothermal effect in the temperature range of 245 – 400 °C (245 – 355 °C respectively) with an energy of 836 to 938 J/g.	Acceptable. Decomposition temperature by DSC; visual observations (capillary method) showed change of colour to brown at 240°C. Test performed under helium atmosphere.	Smeykal, H.; 2010 Smeykal, H.; 2011

section (Annex point)	study	purity	method	results	comment	reference
B.2.1.4 (IIA 2.2)	Relative density	99.4% 97.6%	EC A.3, OECD 109, OPPTS 830.7300	Active substance, pure: D_4^{20} = 1.43 Active substance, technical: D_4^{20} = 1.52	Acceptable	Bogdoll, B.; Strunk, B.; 2011 Eyrich, U.; Bogdoll, B.; 2011
B.2.1.5 (IIA 2.3.1)	Vapour pressure	99.9%	EC A.4, OECD 104	Extrapolated: 9.1 x 10^{-7} Pa for 20 °C 1.7 x 10^{-6} Pa for 25 °C 2.6 x 10^{-5} Pa for 50 °C	Acceptable	Smeykal, H.; 2008
B.2.1.6 (IIA 2.3.2)	Volatility, Henry's law constant		Calculation.	Henry's law constant at 20 °C in distilled water (pH: 7.0) 8.2 x 10^{-8} Pa.m^3.mol^{-1} Henry's law constants at 20 °C at different pH values: at pH 4: 8.2 x 10^{-8} Pa.m^3.mol^{-1} at pH 9: 8.8 x 10^{-8} Pa.m^3.mol^{-1} A vapour pressure of 9.1 x 10^{-7} Pa (20 °C) and the follwing water solubility values at • pH 4: 3.2 g/L pH 9: 3.0 g/L were used to calculate the Henry's law constant.	Acceptable	Bogdoll, B.; Eyrich, U.; 2011

section (Annex point)	study	purity	method	results	comment	reference
B.2.1.7 (IIA 2.4.1)	Appearance: physical state	99.4% 97.6%	Visual	Active substance, pure (at 21°C): white powder Active substance, technical (at 23°C): beige powder	Acceptable	Bogdoll, B.; Strunk, B.; 2011 Eyrich, U., Bogdoll, B.; 2011
B.2.1.8 (IIA 2.4.1)	Appearance: colour	99.4% 97.6%	visual	Active substance, pure (at 21°C): white powder Active substance, technical (at 23°C): beige powder	Acceptable	
B.2.1.9 (IIA 2.4.2)	Appearance: odour	99.4% 97.6%	OPPTS 830.6304	active substance, pure (at 21°C): weak, not characteristic Active substance, technical (at 23°C): distinct, solvent-like odour		Bogdoll, B.; Strunk, B.; 2011; Eyrich, U., Bogdoll, B.; 2011;

section (Annex point)	study	purity	method	results	comment	reference
B.2.1.10 (IIA 2.5.1)	Spectra (as)	99.4%	OECD 101, UV/Vis spectrum. GLP:Y	UV (methanol) Recorded range of wavelengths: 200 – 800 nm Peak maxima molar absorptivity [nm] [1000 cm²/mol] 213 9615.06 259 25800.49 no peak maxima above 290 nm Buffer solution pH 2 Peak maxima molar absorptivity [nm] [1000 cm²/mol] 214 9388.74 259 26576.75 Buffer solution pH 10 Peak maxima molar absorptivity [nm] [1000 cm²/mol] 213 9996.41 259 25954.64	In the dissociation constant determination (see B.2.1.18) it was concluded that at least in the neutral pH range no repeatable UV spectra could be determined.	Peters, S.; 2009;
		99.4%	OECD 101	FT-IR Assignment of wave number to functional groups, s. report	Acceptable	Peters, S.; 2009;
		99.4%	OECD 101 NMR spectrum.	1H-NMR (600.13 MHz, d3-acetonitrile) 13C-NMR (150.90 MHz, d3-acetonitrile)	Acceptable	Peters, S.; 2009;
		99.4%	OECD 101 mass spectrum.	Mass spectra (LC-MS/ESI$^+$-spectrum) m/z-value assignment 289.1 [M+H]+ 577.3 [2M+H]+	Acceptable	Peters, S.; 2009;

section (Annex point)	study	purity	method	results	comment	reference
B.2.1.10 (IIA 2.5.2)	Spectra (impurities)			None of the impurities present in the active substance as manufactured is of toxicological or environmental significance	Acceptable	
B.2.1.11 (IIA 2.6)	Solubility in water	99.4%	EC A.6, OECD 105 GLP:Y	pH 4 (buffer) 3.2 g/L at 20°C pH 9 (buffer) 3.0 g/L at 20°C In distilled water: pH 7 3.2 g/L at 20°C	Acceptable	Wiche, A., Bogdoll, B.; 2011
B.2.1.12 (IIA 2.7)	Solubility in organic solvents	99.4%	EC A.6, OECD 105	[g/L at 20 °C] methanol > 250 n-heptane 0.0005 toluene 3.7 dichloromethane > 250 acetone > 250 ethylacetate > 250 dimethyl sulfoxide > 250	Acceptable	Eyrich, U., Bogdoll, B.; 2011;
B.2.1.13 (IIA 2.8)	Partition co-efficient	99.4%	ECA.8 OECD 117; High Performance Liquid Chromatography (HPLC) Method.	Determination of the partition coefficient of Flupyradifurone in 1-octanol / water (25 °C) Pow log Pow pH 7 16 1.2	Acceptable	Bogdoll, B.; Stunk, B.; 2011;
B.2.1.15 (IIA 2.9.1)	Hydrolysis rate	Radio chemical purity 99%	Furanone-4-^{14}C] BYI 02960, pure Vial No. C-1116	BYI 02960 is hydrolytically stable at ambient temperature in the range of pH 4 to pH9. 3 minor components were observed during 5 days at 50°C which accounted for a total of 4.9%, none were more than 2.7% of the applied activity in any of the pH	See fate section	Mislankar, S.; Woodard, D., 2011

section (Annex point)	study	purity	method	results	comment	reference
B.2.1.16 (IIA 2.9.2)	Photochemical degradation	Radio chemical purity 99.3%	[Furanone-4-^{14}C] BYI 02960, pure Vial No. C-1116A	1st order half-life for photolytic degradation of BYI 02960 in sterile phosphate buffer (pH 7) was 13.8 experimental hrs.	See fate section	Hall, L.R., 2011
B.2.1.17 (IIA 2.9.3)	Quantum yield	purity 99.4 % w/w	BYI 02960, pure NLL 7780-47-4	A mean quantum yield of **<D** = 0.000138 was calculated on the basis of UV absorption data and the degradation kinetics determined from 2 degradation experiments.	Environmental half-lives of sunlight exposed top surface water layers containing BYI 02960 can be estimated using respective models (GC SOLAR or Kloepffer Model) dependent on season and location of exposure.	Heinemann, O. 2011
B.2.1.18 (IIA 2.9.5)	Dissociation constant (pKa)	purity 99.4 % w/w	OECD 112	No dissociation occurs in aqueous solutions in the pH-range 1< pH <12		Wiche, A., Bogdoll, B.; 2011
B.2.1.19 (IIA 2.10)	Stability in air, photochemical oxidative degradation		Atkinson calculation by AOPWIN™ version 1.92a	The half-life time ($t_{1/2}$) was estimated within a range of 4.4 hours (short-term scenario) to 13.1 hours (long-term scenario), depending on the mean concentration of hydroxyl radicals present in the troposphere. In addition, BYI 02960 is susceptible to reactions with ozone, however, that attack and its resulting chemical half-life is considered to be more slowly by a factor of 2 to 10. As a consequence of the short half life in air, no long-range transport BYI 02960 in the atmosphere is likely to occur nor an accumulation of BYI02960 in the environmental compartment air.	See fate section	Hellpointner, E.;

section (Annex point)	study	purity	method	results	comment	reference
B.2.1.20 (IIA 2.11.1 and 2.11.2)	Flammability and auto-flammability (technical active substance)	Tech. a.s. 97.6%	EEC A.10 GLP:Y	Technical substance is not a highly flammable solid in the sense of the EC guideline (EC) No. 440/2008 Method AIO	Acceptable	Smeykal, H, 2011
B.2.1.21 (IIA 2.12)	Flash point (technical active substance)		Statement	Not applicable. The active substance as manufactured is a solid; its melting point is > 40 °C.		
B.2.1.22 (IIA 2.13)	Explosive properties (technical active substance)	Tech. a.s. 97.6%	EC A.14 OECD 113	Not explosive in the sense of EC guideline A.14	Acceptable	Smeykal, H.; 2011;
B.2.1.23 (IIA 2.14)	Surface tension (technical active substance)	Tech. a.s. 97.6%	EC A.5, OECD 115	Technical substance: 69.1 mN/m at 20°C	Acceptable	Eyrich, U., Bogdoll, B.; 2011;
(IIA 2.15)	Oxidizing properties of the active substance as manufactured	BYI 02960, technical PFV107N 004 purity 97.6 % w/w	EC A.17	Flupyradifurone (BYI 2960) has no oxidizing properties in the sense of EC guideline A.17.	Acceptable	Smeykal, H.; 2011;

section (Annex point)	study	purity	method	results	comment	reference
(IIA 2.17.1)	Storage stability (technical active substance)	BYI 02960, technical 2009-000239 purity 96.6% PFV087N 002 purity 98.7% PFV087N 007 purity 98.6%	OPPTS 830.6317	The results from 24 months stability study at ambient temperature (22.1°C) and 30°C showed Flupyradifurone to be stable in polypropylene and polyethylene containers. Even at elevated temperature no decomposition of the test substance and the storage vessels could be established.	Not applicable	Wagner, S.; 2011

Table B.2.1-2 Summary of the physical and chemical properties of the following metabolites BCS-CC98193 (BYI 02960-DFEAF), BCS-CR74729 (BYI 02960-succinamide), BCS-CU93236, BCS-AA56716 (Difluoroacetic acid), IC-0 (6-CNA) are outlined here.

Studies were conducted under GLP and completed to an acceptable standard and results were considered to be acceptable unless specified otherwise.

section (Annex point)	study	purity	method	results	comment	reference
IIA 7.13a	Solubility in water	BCS-CC98193 (BYI 02960-DFEAF) 98.5%	EC A.6 OECD 105 Flask method GLP: y	The solubility C_s at 20 ^oC was determined to be: pH 5: 35.5 g/L pH 7: 36.7 g/L pH 9: 36.4 g/L	Acceptable	Bogdoll B; Strunk B, 2011 [PA11/018]
		BCS-CR74729 (BYI 02960-succinamide) 97.8%	EC A.6 OECD 105 Flask method GLP: y	The solubility C_s at 20 ^oC was determined to be : pH 5 : 5.3 g/L pH 7 : >120 g/L (138.1 g/L) pH 9 : >120 g/L (122.9 g/L)	Buffers were not adequate: pH was adjusted by adding small amounts of aqueous sodium hydroxide and hydrochloric acid solutions to the solution of the test item. Deviation from EC A.6: two samples were taken at identical equilibration times. Considering the measured solubility, the followed procedure is adequate. Acceptable	Wiche A; Ziemer F, 2011 [PA11/078]

section (Annex point)	study	purity	method	results	comment	reference
		BCS-CU93236 97.3%	EC A.6 OECD 105 Flask method GLP: y	The solubility C_s at 20 °C was determined to be : pH 5 : > 175 g/L (179 g/L) pH 7 : > 180 g/L (181 g/L) pH 9 : > 180 g/L (181 g/L)	Deviation from EC A.6: two samples were taken at identical equilibration times. Considering the measured solubility, the followed procedure is adequate. Acceptable	Ziemer F; Strunk B, 2011 [PA11/094]
		BCS-AA56716 (Difluoroacetic acid) 96.7%	EC A.6 OECD 105 Flask method GLP: y	Difluoroacetic acid was miscible with distilled water in any ratio at 20 °C. The solubility at 20 °C was determined to be > 500 g/L in a pH range of 1.6-13.0.	Due to the extremely high water solubility at all pH values a visual evaluation was made. Acceptable	Bogdoll B; Strunk B, 2011 [PA10/042]
		IC-0 (6-CNA) 99.7%	EC A.6 OECD 105 Flask method GLP: y	The solubility at 20 °C was determined to be: Distilled water: 1.43 g/L (pH 2.1 after incubation) pH 4 buffer: 4.62 g/L (pH 3.2 after incubation) pH 10 buffer: 18.6 g/L (pH 4.4 after incubation)	Acceptable	Miya K, 2001 [NCAS 01-129]
IIA 7.13b	Partition co-efficient	BCS-CR74729 (BYI 02960-succinamide) 97.8%	EC A.8 OECD 107 Shake flask method GLP:Y	Partition coefficient at 23 °C pH 5: log P_{OW} = 0.6 pH 7: log P_{OW} = -1.3 pH 9: log P_{OW} = -2.5	Acceptable	Eyrich U; Ziemer F, 2011 [PA11/079]

section (Annex point)	study	purity	method	results	comment	reference
		BCS-CU93236 97.3%	EC A.8 OECD 107 Shake flask method GLP:Y	Partition coefficient at 23 °C pH 5: log P_{OW} = -1.3 pH 7: log P_{OW} = -2.7 pH 9: log P_{OW} = -3.5	Acceptable	Eyrich U; Ziemer F, 2011 [PA11/093]
		BCS-AA56716 (Difluoroacetic acid) 96.7%?	EC A.8 OECD 107 Shake flask method GLP:Y	Partition coefficient at 23 °C pH 5: log P_{OW} = -3.1 pH 7: log P_{OW} = -3.1 pH 9: log P_{OW} = -3.5	Acceptable	Eyrich U; Ziemer F, 2011 [PA10/043]
		IC-0 (6-CNA) 99.7%	EC A.8 OECD 107 Shake flask method GLP:Y	Log P_{OW} = 1.52 at 25 °C (pH 1.98 buffer solution used)	Acceptable	Higashida S, 2001 [NCAS 01-127]
IIA 7.13c	Dissociation constant (pKa)	BCS-CC98193 (BYI 02960-DFEAF) 98.5%	OECD 112 Spectrophotometric method GLP:Y	No dissociation constant pKa was found in aqueous solution in the pH-range of 2<pH<12. BCS-CC98193 shows no acidic or basic properties in the range of approximately 2<pHa<12.	Acceptable	Wiche A; Bogdoll B, 2011 [PA11/021]
		BCS-AA56716 (Difluoroacetic acid) 96.7%	OECD 112 Titration method GLP:Y	pKa = 1.57	Acceptable	Winkler S, 2011 [20100366.02]

section (Annex point)	study	purity	method	results	comment	reference
		IC-0 (6-CNA) 99.7%	OECD 112 Titration method GLP:Y	pKa = 3.28	Acceptable	Miya K, 2001 [NCAS 01-140]
IIA7.13d	Vapour pressure	BCS-CC98193 (BYI 02960-DFEAF) 98.5%	EC A.4 OECD 104 Vapour pressure balance GLP:Y	2.1×10^{-5} Pa (20 ^{o}C) 4.7×10^{-5} Pa (25 ^{o}C) 2.0×10^{-3} Pa (50 ^{o}C) Vapour pressure could be measured above 55 ^{o}C. Vapour pressures at lower temperatures have been extrapolated.	According to EC A.4, the vapour pressure balance method is recommended for the range of 10^{-3} - 1 Pa. For the vapour pressures determined at 20 ^{o}C and 25 ^{o}C, the gas saturation method would have been more appropriate. Acceptable	Dornhagen J, 2011 [20110091.01]

B.2.3 Summary of physical and chemical properties

B.2.3.1 Active substance

Physical and chemical properties of the active substance

Flupyradifurone is an insecticide. Its vapour pressure and volatility are very low. The solubility in water is about 3.2 g/L at a range of pH between 4 and 9. With a log Pow of 1.2 it has no bioaccumulative potential in lipophilic matrices. Flupyradifurone is hydrolytically stable under acidic, neutral and under alkaline conditions at ambient temperature. The hydrolytic degradation is negligible under acidic, neutral and alkaline conditions. Flupyradifurone is rather susceptible for reactions with hydroxyl radicals with photochemical degradation process to contribute significantly to the overall degradation of the substance in case of its occurrence in the atmosphere. Its flammability, explosive and oxidizing properties are not critical

B.2.3.2 Plant protection product

Flupryadifurone (BYI 2960)SL 200 is a brown liquid with a weak characteristic odour.. The product has a flash point > 100°C, an auto-ignition temperature of 420°C and has neither explosive nor oxidizing properties. The pH of a 1% dilution is 5.4. When diluted, the recommended end-use concentration is not surface active. An accelerated storage test of 14 days at 54°C, has been performed. A shelf life study after 2 years at ambient temperature in HDPE has indicated the physico-chemical stability of the product.

B.3 Data on application and further information

B.3.1 Data on application relevant to the active substance (Annex IIA 3.1 to 3.6)

B.3.1.1 Function (Annex IIA 3.1)

The active substance flupyradifurone (BYI 02960) will be used as an insecticide.

B.3.1.2 Effects on harmful organisms (Annex IIA 3.2.1)

Flupyradifurone interacts with insect nicotinic acetylcholine receptors, a class of neurotransmitter-gated cation channels which are involved in excitatory neurotransmission, a target also known for neonicotinoid insecticides. Blockage of these receptors leads to paralysis and death of the target insects.

B.3.1.3 Translocation in plants (Annex IIA 3.2.2)

Flupyradifurone is a systemic insecticide. After uptake into the plant, Flupyradifurone is translocated acropetally in the xylem, in direction of the transpiration stream and is translaminarily distributed into adjacent plant cells.

B.3.1.4 Fields of use (Annex IIA 3.3)

Intended for agricultural use. Control of aphids in lettuce and hop were chosen as representative uses for the representative formulation, the product Sivanto (flupyradifurone 200SL)

B.3.1.5 Pests controlled and crops protected (Annex IIA 3.4.1, 3.4.2)

The active substance Flupyradifurone according to the applicant, exhibits high activity especially against sucking insects like aphids and whiteflies. Control of aphids in lettuce and hop were chosen as representative uses for the representative formulation, the product Sivanto (flupyradifurone 200SL)

Crops	**Harmful organisms***
Lettuce	Lettuce aphid *Nasonovia ribisnigri*
Hop	Hop Aphid *Phorodon humili*

B.3.1.6 Mode of action (Annex IIA 3.5.1)

Flupyradifurone interacts with insect nicotinic acetylcholine receptors, a class of neurotransmitter-gated cation channels which are involved in excitatory neurotransmission, a target also known for

neonicotinoid insecticides. Blockage of these receptors leads to paralysis and death of the target insects.

After uptake into the plant, Flupyradifurone is translocated acropetally in the xylem, in direction of the transpiration stream and is translaminarily distributed into adjacent plant cells.

B.3.1.8 Information on the possible occurrence of the development of resistance or cross-resistance (Annex IIA 3.6)

Studies on the possible occurrence of the development of resistance or cross resistance are evaluated in Volume 3, Annex B, section B10 efficacy in chapter 10.2

B.3.2 Data on application relevant to the plant protection product (Annex IIIA 3)

Sivanto SL 200 g/L, or flupyradifuone SL200, is a soluble concentrate (SL) containing 200 grams per litre (g/L) of Flupyradifurone for use on lettuce and hop .

B.3.2.1 Field of use (Annex IIIA 3.1)

Intended for agricultural use. Control of aphids in lettuce and hop were chosen as representative uses for this evaluation.

B.3.2.2 Nature of the effects on harmful organisms (Annex IIIA 3.2)

Flupyradifurone interacts with insect nicotinic acetylcholine receptors, a class of neurotransmitter-gated cation channels which are involved in excitatory neurotransmission, a target also known for neonicotinoid insecticides. Blockage of these receptors leads to paralysis and death of the target insects.

B.3.2.3 Pests controlled and crops protected (Annex IIIA 3.3)

Crops	**Harmful organisms***
Lettuce	Lettuce aphid *Nasonovia ribisnigri*
Hop	Hop Aphid *Phorodon humili*

Rate of application (Annex IIIA 3.4)

See the GAP (Table 3.3.1 Summary of intended uses in chapter B.3.3 in this document)

Concentration of active substance in material used (Annex IIIA 3.5)

The representative formulation for flupyradifurone is Sivanto SL 200 g/L, this is a soluble concentrate (SL) containing 200 grams per litre (g/L) of Flupyradifurone.

Description of the method of application, type of equipment used and type and volume of diluent per unit of area or volume (Annex IIIA 3.6)

Flupyradifurone 200SL (Sivanto) is applied with traditional foliar sprayer.

Number and timing of applications and duration of protection afforded (Annex IIIA 3.7)

See the GAP (Table 3.3.1 Summary of intended uses in chapter B.3.3 in this document)

B.3.2.4 Minimum waiting periods or other precautions between last application and sowing or planting of succeeding crops. Limitations on choice of succeeding crops (Annex IIIA 3.8)

See the GAP (Table 3.3.1 Summary of intended uses in chapter B.3.3 in this document)

B.3.3 Summary of data on application

See table 3.3.1: Summary of intended uses.

Table 3.3.1 Summary of intended uses

Crop and/ or situation (a)	Country	Product Name	F G or I (b)	Pests or Group of pests controlled (c)	Formulation		Application				Application rate per treatment			PHI (days) (l)	Remarks: (m)
					Type (d-f)	Conc. of as (i)	method kind (f-h)	growth stage & season (j)	number min max (k)	interval between applications (min)	kg as/hL min max	water L/ha min max	kg as/ha min max		
Hops	N-EU (residue zone)	Sivanto	F	Aphids, *Phorodon humuli,*	SL	200	spray	BBCH 31-75 May July.	1	n.a.	0,0045-0,0075	2000-3300	0.150	21	Biannual application proposed
Lettuce	N/S-EU (residue zone)	Sivanto	F	Aphids, *Nasonovia ribisnigri*	SL	200	spray	BBCH 12-49 May--Oct	1	n.a.	0,0125-0,0250	500-1000	0.125	10	Max 1 application per **24** months
Lettuce	N/S-EU (residue zone)	Sivanto	F	Aphids, *Nasonovia ribisnigr*	SL	200	spray	BBCH 41-49 May--Oct	1	n.a.	0,0125-0,0250	500-1000	0.125	3	Max 1 application per **12** months
Lettuce (soil bound)	N-EU S-EU (residue zone)	Sivanto	G	Aphids, *Nasonovia ribisnigri,*	SL	200	spray	BBCH 12-49	2	10	0,0125-0,0250	500-1000	0.125	3	Max 2 applications per 12 months

Remarks:
a) in case of group of crops the Codex classification should be used
b) Outdoor of field use (F), or glasshouse application (G)
c) e.g. biting and sucking in insects, soil born insects, foliar fungi
d) e.g. wettable powder (WP), emulsifiable concentration (EC), granule (GR)
e) Use CIPAC/FAO Codes where appropriate
f) All abbreviations used must be explained
g) Method, e.g. high volume spraying, low volume spraying, spreading, dusting, drench
h) Kind, e.g. overall, broadcast aerial spraying, row, individual plant, between the plants
i) g/l or g/L
j) Growth stage at last treatment
k) The minimum and maximum number of application possible under practical conditions of use must be provided
l) PHI - Pre Harvest Interval
m) Remarks may include: Extent of use/ economic importance/restrictions

B.3.4 Further information on the active substance (Annex IIA 3.7 to 3.9)

B.3.4.1 Recommended methods and precautions concerning handling, storage, transport or fire (Annex IIA 3.7)

B.3.4.1.1 Handling

Advice on safe handling

Use only in area provided with appropriate exhaust ventilation.

Hygiene measures

Avoid contact with skin, eyes and clothing.
Keep working clothes separately.
Wash hands immediately after work, if necessary take a shower.
Remove soiled clothing immediately and clean thoroughly before using again.
Garments that cannot be cleaned must be destroyed (burnt).

B.3.4.1.2 Storage

Requirements for storage areas and containers

Store in original container.
Keep containers tightly closed in a dry, cool and well-ventilated place.
Store in a place accessible by authorized persons only.
Protect from frost.
Keep away from direct sunlight.

Advice on common storage

Keep away from food, drink and animal feedingstuffs.

Suitable materials

HDPE (high density polyethylene)

B.3.4.1.3 Transport

ADR/RID/ADN

UN number:	**3082**
Proper shipping name:	ENVIRONMENTALLY HAZARDOUS SUBSTANCE, LIQUID, N.O.S., (FLUPYRADIFURONE SOLUTION)
Transport hazard class(es):	9
Packing group:	III

Environm. Hazardous Mark: YES
Hazard no.: 90
Tunnel Code: E
This classification is in principle not valid for carriage by tank vessel on inland waterways. Please refer to the manufacturer for further information.

IMDG

UN number: **3082**
Proper shipping name: ENVIRONMENTALLY HAZARDOUS SUBSTANCE, LIQUID,, N.O.S., (FLUPYRADIFURONE SOLUTION)
Transport hazard class(es): 9
Packing group: III
Marine pollutant: YES

IATA

UN number: **3082**
Proper shipping name: ENVIRONMENTALLY HAZARDOUS SUBSTANCE, LIQUID, N.O.S., (FLUPYRADIFURONE SOLUTION)
Transport hazard class(es): 9
Packing group: III
Environm. Hazardous Mark: YES

Transport in bulk according to Annex II of MARPOL 73/78 and the IBC Code

No transport in bulk according to the IBC Code.

Fire

Extinguishing media

Suitable extinguishing media:

Water spray
Carbon dioxide (CO2)
Foam
Sand

Special hazards arising from the substance or mixture:

In the event of fire the following may be released:
Hydrogen chloride (HCl)

Hydrogen cyanide (hydrocyanic acid)
Hydrogen fluoride
Carbon monoxide (CO)
Nitrogen oxides (NOx)

Advice for firefighters

Special protective equipment for fire-fighters

In the event of fire and/or explosion do not breathe fumes.
In the event of fire, wear self-contained breathing apparatus.

Further information

Contain the spread of the fire-fighting media.
Do not allow run-off from fire fighting to enter drains or water course

B.3.4.2 Procedures for destruction or decontamination of the active substance, contaminated packaging and contaminated material

B.3.4.2.1 Controlled incineration

In accordance with current regulations and, if necessary, after consultation with the site operator and/or with the responsible authority, the product may be taken to a waste disposal site or incineration plant. Not completely emptied packagings should be disposed of as hazardous waste.

B.3.4.2.2 Others

Waste key for the unused product: 020108 agrochemical waste containing dangerous substances

B.3.4.3 Emergency measures in the case of an accident

Personal precautions:

In normal use and handling conditions please refer to the label and/or leaflet. In all other cases the following recommendations would apply.

Respiratory protection:

If product is handled while not enclosed, and if contact may occur: Wear respirator with an organic vapours and gas filter mask, (protection factor 10) conforming to EN140 type A or equivalent. Respiratory protection should only be used to control residual risk of short duration activities, when all reasonably practicable steps have been taken to reduce exposure at source e.g. containment and/or local extract ventilation. Always follow respirator manufacturer's instructions regarding wearing and maintenance.

Hand protection:
Wear CE Marked (or equivalent) nitrile rubber gloves (minimum thickness 0,40 mm). Wash when contaminated. Dispose of when contaminated inside, when perforated or when contamination outside cannot be removed. Wash hands always before eating, drinking, smoking or using the toilet.

Eye protection:
Wear goggles conforming to EN166 (Field of Use 5 or equivalent).

Skin and body protection:
Wear standard coverall and type 3 suit. Wear two layers of clothing wherever possible. Polyester/cotton or cotton overalls should be worn under chemical protection suit and should be professionally laundered frequently. If chemical protection suit is splashed, sprayed or significantly contaminated, decontaminate as far as possible, then carefully remove and dispose of as advised by manufacturer.

Protective measures
If product is handled while not enclosed, and if contact may occur: Complete suit protecting against chemicals

Environmental precautions:
Do not allow to get into surface water, drains and ground water
Methods for cleaning up or taking up:
Soak up with inert absorbent material (e.g. sand, silica gel, acid binder, universal binder, sawdust). Clean contaminated floors and objects thoroughly, observing environmental regulations. Keep in suitable, closed containers for disposal.

B.3.4.4 Summary of further information and assessment

No further information.

B.3.5 Further information of the plant protection product (Annex IIIA 4)

Product name: Sivanto SL 200 g/L

B.3.5.1.1 Packaging, compatibility on the preparation with proposed packaging materials (Annex IIIA 4.1)

Description and specification of the packaging

Specific Requirement:	Examples:
■ Material (declare the primary packaging material from **inside to outside**)	Bottle / Canister: HDPE
■ Capacity:	Standard bottle / canister up to 10 liter, packed in outer corrugated fibreboard: • 20 x 0.250 liter • 20 x 0.500 liter • 12 x 1 liter • 4 x 3 liter • 4 x 5 liter • 2 x 10 liter Standard canister / IBC over 10 liter such as: • 20 liter • 25 liter • 50 liter • 200 liter • 640 liter • 1000 liter
■ Type of closure and size of opening	Screw cap 36-50-63 mm (with HF seal or internal wad) - to fit container neck as defined in ECPA One Trip Container Guidelines. Tri – Sure, S 56 x 4 mm, guarantees closure. Screw cap DN 50 guarantees closure and DN 150 guarantees closure.
■ Application devices	None

B.3.5.1.2 Packaging suitability

Statement of compliance:

All packagings comply with ADR regulations and have been tested using the ADR test methods appropriate to the pack type and material and classification of the contents.

B.3.5.1.3 Packaging resistance

The resistance of packaging material to its contents has been tested in accordance with GIFAP Technical Monograph No 17 (May 1993).

B.3.5.2 Procedures for cleaning application equipment (Annex IIIA 4.2)

All application equipment and contaminated protective clothing should be washed/cleaned with water or a dilute detergent solution and thoroughly rinsed. Care should be taken not to spill the contaminated

washings from application equipment into waste water channels. Contaminated cleaning liquids should be disposed safely according to local regulations.

Application equipment

Field spraying equipment should be sufficiently cleaned in order to avoid product left over. Cleaning of field spaying equipment is in general an essential part of the recommendations for use of plant protection products.

Empty the contents of the spraying equipment completely onto the field just sprayed. Remove all filters and nozzles, scrub clean and rinse them with clean water. Put 10 % clean water into the tank to cover the agitator and add about 0.5% liquid detergent. Operate a tank flushing system if fitted. Circulate water through the pump and controls for at least one minute. Drain sprayer, collect washings. Repeat procedure once more. Pump last washing water out through boom feed hoses and pipes. Collect washings. Clean off the outside of the sprayer using minimum water volumes. Collect washings. Replace cleaned nozzles and filters. Collect and put all washings back into the tank and spray out onto the field headland, or otherwise safely dispose of them. Ensure the sprayer systems are completely drained before storage. Plant protection equipment should always be stored in a properly designated storage facility.

Protective clothing

All contaminated clothing should be washed / cleaned with a dilute detergent solution and thoroughly rinsed with clean water.

Impermeable overalls, boots and face shields should be washed clean and dried.

Permeable overalls should be laundered after use.

Disposable overalls and gloves should be washed and disposed of as contaminated waste.

Gloves and boots should be washed clean, if necessary on the insides as well.

B.3.5.3 Re-entry periods, necessary waiting periods or other precautions to protect man, livestock and the environment (Annex IIIA 4.3)

Pre-harvest interval (in days)

Crop	Pre-harvest Interval (PHI)
hop:	21
lettuce, field	10
lettuce, glasshouse	3

Re-entry period (in days) for livestock, to areas to be grazed.

Re-entry period needs not to be established as the representative crops are not grazed.

Re-entry period (in hours or days) for man to crops, buildings or spaces treated

A safe re-entry or handling of treated crops is possible when spray deposit has dried.

Withholding period (in days) for animal foodstuffs

Lettuce:
Due to the time between last treatment and harvest, as defined by the GAPs, it is not necessary to set a withholding period for use of treated plants as animal feeding stuffs. The withholding period is covered by the vegetation period of the crop. However, a poultry feeding study with parent BYI 02960 was conducted at dose rates which reflect maximum possible exposure to livestock based on uses in numerous crops, many of which will be submitted in a separate document. That study covers all aspects of residues in livestock and thus no specific withholding period is required.

Hops:
Not relevant for hops since they are not used as animal feeding stuffs.

Waiting period (in days) between application and handling treated products

Given the toxicological profile of the product and the residue levels at harvest in treated agricultural commodities, there is no need to define a waiting period between application and handling treated products.

Waiting period (in days) between last application and sowing or planting of succeeding crops

A full program of residue trials in rotational crops is presented either in this dossier (the "main", multi-crop, multi-rotation study) or in a separate document (multiple additional crops). The data collected in these studies yield information on the level of residues to be expected in following crops, and are reflected in the dietary risk assessment. Therefore, no waiting period needs to be specified.

Conditions under which the product should not be used

Product should not be used in windy conditions in order to avoid drift into water bodies.

B.3.5.4 Recommended methods and precautions concerning: handling, storage, transport or fire (Annex IIIA 4.4)

For details see Material Safety Data Sheet.

Warehouse storage

Keep out of the reach of children.
Keep away from food, drink and animal feeding stuffs.
When using, do not eat, drink or smoke.
Keep away from source of ignition.
Store in the original container under usual warehouse conditions! Keep containers tightly closed in a cool, well-ventilated place.
Store in a place accessible by authorized persons only! Keep away from direct sunlight and protect again frost.
For more information see:

- Guidelines for the safe handling of pesticides during their formulation, packing, storage and transport (GCPF).
- Guidelines for the safe warehousing of crop protection products (GCPF).

User level storage

Keep out of the reach of children.
Keep away from food, drink and animal feeding stuffs.
When using, do not eat, drink or smoke.
Keep away from source of ignition.

Transport

Risks during transport of product are minimal. Follow the general rules and good practice for transport and the Dangerous Goods regulations. Do not stow the product together with food, feed and consumable items.
Transport classification of the product in Europe is:
Road and rail (ADR and RID): UN3082 (environmentally hazardous substance), Hazard No. 90.

Fire

Extinguish fires with foam or carbon dioxide (CO_2), sand or water spray. Do not allow run-off from fire fighting to enter drains or water courses, e.g. by bundling the area with sand or earth.

Wear a self-contained breathing apparatus. Remove product from areas of fire or otherwise cool containers with water in order to avoid pressure being built up due to heat.
Water should be used as sparingly as possible and if contaminated it must not come in contact with surface water. It must be collected and burned in a commercial incinerator. If burning facilities are inadequate, obtain the manufacturer's advice on decontamination methods.

Protective clothing and equipment – Nature
If product is handled such that there is a risk:

Respiratory protection:	If product is handled while not enclosed, and if skin contact may occur: Full mask Multi-range filter ABEK/P2
Hand protection: Eye protection: Hygiene measures:	PVC or other plastic material gloves Safety glasses with side-shields Avoid contact with skin, eyes and clothing. Keep working clothes separately. Wash hands before breaks and at the end of workday. Wash hands immediately after work, if necessary take a shower. Remove soiled or soaked clothing immediately and clean thoroughly before using again. Garments that cannot be cleaned must be destroyed (burnt).

Protective clothing and equipment – characteristics

Respiratory protection	If product is handled while not enclosed, and if skin contact may occur: Full mask Multi-range filter ABEK/P2
Hand protection	PVC or other plastic material gloves
Eye protection	Safety glasses with side-shields

Suitability and effectiveness of the protective clothing and equipment

Safety glasses with side-shields are recommended to protect eyes from contact with the product. Protective clothing is recommended as routine hygienic measure. Chemical resistant gloves are well known to sufficiently protect hands from contact with the product handled.

Procedures to minimize the generation of waste

Product

To minimise product waste, users are required not to prepare more than they will use for the treatment.

Package

To minimise package waste, empty and rinsed containers should be delivered to a local container collection programme, where available. Otherwise, they should be rendered unusable, e.g. by puncturing, and disposed in accordance with local regulations.

Packaging that cannot be cleaned should be disposed of as product waste. It must be incinerated in an authorised special waste incineration plant. Comply with local legislation.

To minimise generation of leftovers, users are recommended to store not more than will be consumed within the shelf life period of the product.

Information on likely combustion products in the event of fire

The following can be released in case of fire:

Carbon dioxide (CO_2) Carbon monoxide (CO) Nitrous gases (NOx) Hydrogen cyanide (hydrocyanic acid)

Detailed procedures in the event of an accident during transport

Containment of spillages

Keep people and animals away.

Do not discharge into drains / surface water / groundwater. Cover any spilled liquid with absorbent material such as sand, earth or a proprietary absorbent material. After the liquid has been absorbed, carefully sweep it up into a disposable container and tightly seal. Dispose by incineration in an authorised special waste incineration plant. Comply with local legislation. For larger quantities, please contact manufacturer.

If spillage enters drains leading to sewage works, inform local company immediately. If spillage enters rivers or watercourses, inform the Environmental Agency.

Decontamination of areas, vehicles and buildings

Take up with adsorbent material (e.g. sand, earth or a proprietary absorbent material).
Transfer collected material to heavy duty plastic drums and keep safe for disposal. Clean contaminated floors and objects thoroughly, observing environmental regulations.

Disposal of damaged packaging, adsorbents and other material

After the liquid has been absorbed (sand, earth or proprietary absorbent material), carefully sweep it up into a disposable container and tightly seal. Damaged packaging and adsorbents should be collected into heavy duty plastic drums.

Containers and drums can be taken to waste disposal site or incineration plant, after consultation with site operator and/or with the responsible authority. Dispose of by incineration in an authorised special waste incineration plant. Comply with local legislation. For larger quantities, contact manufacturer.

Protection of emergency workers and bystanders

Keep people and animals away. Avoid contact with spilled product or contaminated surfaces and wear personal protective equipment (see Section IIIA1 4.4.6).

In the event of fire and/or explosion, do not breathe fumes. Wear self-contained breathing apparatus for fire fighting if necessary. Remove product from area of fire or otherwise cool containers with water in order to avoid pressure being built up due to heat.

When dealing with a spillage, do not eat, drink or smoke. Remove soiled or soaked clothing immediately. Clean hands and face at work intervals and after work.

First aid measures

General advice:	Move out of dangerous area. If the patient is likely to become unconscious, place and transport in stable sideways position. Remove soiled or soaked clothing immediately.
After inhalation:	Move the patient to fresh air and keep at rest. Call a physician immediately.
After eye contact:	In the case of contact with eyes, rinse immediately with plenty of water. Call a physician immediately.
After skin contact:	After contact with skin, wash immediately with soap and plenty of water. Call a physician immediately.
After ingestion:	Do not induce vomiting. Wash out mouth with water. Call a physician Immediately.

B.3.5.6 Procedures for destruction or decontamination of the plant protection product and its packaging (Annex IIIA 4.6)

B.3.5.6.1 Possibility of neutralisation

No neutralization procedure (e.g. reaction with alkali to form less toxic compounds) is necessary for Flupyradifurone SL 200.

B.3.5.6.3 Others

No other methods for disposal of Sivanto SL 200 g/L are available.

B.3.5.7 Summary of further information and assessment

No further information.

B.4 Proposals for classification and labelling

B.4.1 Proposals for the classification and labelling of the active substance (Annex IIA 10)

Proposed classification based on Regulation EC 1272/2008:

Physical and chemical properties
No classification is required.

Human health effects
Flupyradifurone (BYI 02960) needs to be classified as Acute oral toxic Cat. 4 H302 according to Regulation (EC) 1272/2008. Flupyradifurone does not need to be classified on the basis of its acute dermal, and inhalation toxicology in rats (Category 5/ Unclassified). Flupyradifurone is considered not irritating to skin and eyes (Category 5/ Unclassified). Flupyradifurone does not have sensitising properties in a LLNA (Category 5/ Unclassified).

Ecotoxicological properties

Category:	Acute 1 and Chronic 1
GHS picogram:	GHS09
Signal word:	Warning
Hazard statement:	H400 “Very toxic to aquatic life”
	H410 “Very toxic to aquatic life with long lasting effects “
Precautionary statements:	(the following may be considered):
	P273 “ Avoid release to the environment”,
	P391 “ Collect spillage”
	P 501 “ Dispose of contents/container to … [in accordance with national/international regulations (to be specified)].

Explanation:
The standard species fish, daphnids and algae are not sensitive to flupyradifurone (L/EC50 >70 mg/L). However, aquatic insects are much more sensitive. The classification is based on the lowest acute L/EC_{50} of flupyradifurone, which is <1 mg/L (*C.riparius* EC50 = 0.0617 mg/L). Therefore, flupyradifurone is classified in Category Acute 1.

Flupyradifurone is considered not ready biodegradable (see LoE fate and behaviour). There are adequate chronic toxicity data available. The NOECs for fish and daphnids are >1 mg/L, but as said above, daphnids are not sensitive to flupyradifurone and it is therefore necessary to take into account other, sensitive, species. The lowest NOEC is <0.1 mg/L (0.010 mg/L for *C. riparius*). Therefore, flupyradifurone is classified in Category Chronic 1.

The M-factor for flupyradifurone is 10 based on both acute and chronic toxicity.

The precautionary statements may be chosen according to national regulations.

B.4.2 Proposals for the classification and labelling of preparations (Annex IIIA 11.3 and 11.4)

Proposed classification based on Regulation EC 1272/2008:

Physical and chemical properties
No classification is required.

Human health effects
The formulation BYI 02960 SL 200 g/L does not need to be classified on the basis of its acute oral, dermal toxicology. According to Regulation (EC) 1272/2008 formulation BYI 02960 SL 200 g/L is classified with H332, Harmful if inhaled (R20, Harmful by inhalation according to Directive 67/548/EEC). BYI 02960 SL 200 g/L is considered not irritating to skin and eyes.
BYI 02960 SL 200 g/L has sensitising properties in a LLNA and is classified with H317 (may cause an allergic skin reaction)/R43 (may cause sensitization by skin contact).

Ecotoxicological properties

Category:	Acute 1 and Chronic 1
GHS picogram:	GHS09
Signal word:	Warning
Hazard statement:	H400 “Very toxic to aquatic life”
	H410 “Very toxic to aquatic life with long lasting effects “
Precautionary statements:	(the following may be considered):
	P273 “ Avoid release to the environment”,
	P391 “ Collect spillage”
	P 501 “ Dispose of contents/container to … [in accordance with national/international regulations (to be specified)].

Explanation:
Toxicity studies with the preparation on the standard species fish, daphnids and algae are available and it is clear that these species are not sensitive to Sivanto (BYI 02960 SL 200) (L/EC50 >100 mg formulation/L). However, aquatic insects are much more sensitive to the a.s.. There is only a chronic study available on aquatic insects for the preparation but not an acute one. Therefore, it would underestimate the acute toxicity to base the classification of the preparation on the available studies.

Instead, the acute classification is based on the summation method. Flupyradifurone is classified as H400 based on its lowest acute L/EC_{50}, which is 0.0617 mg/L, and has an M-factor of 10. The concentration of flupyradifure in the preparation (ca.20%) multiplied by the M-factor (10) is greater than 25%. Therefore, the preparation is also classified in Category Acute 1 (H400). Since this is the worst-case acute classification, the other components of the product do not need to be discussed.
The lowest chronic NOEC for the preparation is ca. 0.06 mg preparation/L (for *C. riparius)*. Therefore, the preparation is classified in Category Chronic 1 (with H410).
The precautionary statements may be chosen according to national regulations.

B.4.3 References relied on

The proposed classification and labelling is based on the physical-chemical, toxicological and ecotoxicological evaluation as presented in section B.2, B.6 and B.9, respectively.

B.5 Methods of analysis

B.5.1 Analytical methods for technical active substance (IIA 4.2.1)) and plant protection product (IIIA 5.2.1)

B.5.1.1 Technical active substance (IIA 4.2.1)

STUDY 1

Reference	:	zur Mühlen, U., Wagner S., 2011 (IIIA 4.2.1/01)	GLP statement	:	-
Type of study	:	Determination of technical grade active substance HPLC -ISTD	Guideline	:	SANCO 3030/99 rev 4
Year of execution	:	2011	Acceptability	:	Acceptable
Test substance	:	Flupyradifurone (BYI 2960)	Method reference	:	AM008809MP1

STUDY 2

Reference	:	Wagner S., 2011 (IIIA 4.2.1/02)	GLP statement	:	-
Type of study	:	Validation of AM008809MP1 Flupyradifurone (BYI 02960) Determination of technical grade active substance HPLC - ISTD	Guideline	:	SANCO 3030/99 rev 4
Year of execution	:	2011	Acceptability	:	Acceptable
Test substance	:	Flupyradifurone (BYI 2960)	Method reference	:	VB1-AM008809MP1

Description of the method

The active substance Flupyradifurone is determined in the technical material as manufactured by reversed-phase liquid chromatography (HPLC) using Diethylphthalate as internal standard (ISTD). The quantitative determination is performed with a specific UV detector (DAD detector) at 225 nm.

Results

Linearity	5 concentrations with double measurements; range 84.3 – 120.4% (corresponding to 84.3 mg/100 mL to 120.4 mg/100 mL); correlation coefficient r^2: 0.9999; regression equation and chromatograms are given in the report; the function is linear in the operating range.
Precision Repeatability	5 synthetic samples with double measurements; no outliers are reported, RSD: 0.30 %; acceptable according to the Horwitz
Accuracy	5 synthetic samples with double measurements; mean recovery: 99.87 %; RSD:
Specificity/Interference	Retention times and UV-spectra from reference substance, sample and spiked sample were compared. The UV-spectra show no spectral differences, the corresponding retention times are identical. Chromatograms of reference substances, sample and spiked sample were checked and found to be free of interfering compounds.

Conclusion

The HPLC-method AM008809MP1 for the determination of Flupyradifurone (BYI 02960) in technical grade active substance is found to be valid.

Guidelines & Limitations

None.

B.5.1.2 Plant protection product (IIIA 5.2.1)

STUDY 3

Reference	:	Zitzmann W., 2009 (IIIA 5.2.1/01)	GLP statement	:	-
Type of study	:	Analytical methods for plant protection product	Guideline	:	SANCO 3030/99 rev 4

Test substance	:	Flupyradifurone (BYI 2960) SL 200, specification number 102000021884	Method reference	:	AM012609MF1

STUDY 4

Reference	:	Kienow A. Seidel E.., 2010 (IIIA 5.2.1/02)	GLP statement	:	-
Type of study	:	Analytical methods for plant protection product Validation of HPLC-method AM012609MF1 Determination of BYI 02960 in formulations BYI 02960 SL 200 (200 g/L)	Guideline	:	SANCO 3030/99 rev 4
Year of execution	:	2010	Acceptability	:	Acceptable
Test substance	:	Flupyradifurone (BYI 2960) SL 200, specification number 102000021884	Method reference	:	VB2-AM012609MF1

Determination of BYI 02960 in formulations Assay HPLC, external standard. The HPLC method AM012609MF1 is applicable for the determination of the content of Flupyradifurone (BYI 2960) in formulations (*e.g*. ‘Flupyradifurone (BYI 2960) SL 200’).

Description of the method

The active substance (BYI 02960) is separated from formulation constituents by reversed phase chromatography using isocratic elution. After UV detection (280 nm), the quantitative evaluation is carried out by comparing the peak areas with those of reference substances, using an external standard of BYI 02960.

Results

Linearity	6 concentrations with single injections; range 50 -150%; correlation co-efficient $r_{K:}$ 0.9999; regression equation: y = 73.3404x + 21.4446 Chromatograms are given; the function is linear in the operating range.
Precision	6 samples from one batch; single injection; no outliers; acceptable according to the Horwitz equation; relative standard deviation RSD: 0.31%.
Accuracy	6 samples of laboratory-prepared synthetic formulation; mean recovery: 100.3%, confidence interval of recovery: 100.28 ± 0.98 the method shows no constant or proportional systematic error.
Specificity	The UV-spectra of active substance and reference substance show no spectral difference; the retention times of active substance and reference substance are identical.
Interference	No interferences are found.

Conclusion

The HPLC method AM012609MF1for the determination of Flupyradifurone (BYI 2960) in the formulation Flupyradifurone (BYI 2960) SL 200, specification number 102000021884 is found to be valid.

Guidelines & Limitations

None.

B.5.2 Analytical methods (residue) for plants, plant products, foodstuffs of plant and animal origin, feedingstuffs (IIA 4.3 and IIIA 5.4, IIIA 5.6 IIIA 5.7,)

Method 01330 (including its modification M001) was developed as an *enforcement method*. It determines BYI 02960 and its metabolite DFA by HPLC-MS/MS. Matrix-matched standards were used for quantification. The LOQs were generally 0.01 mg/kg and 0.02 mg/kg for BYI 02960 and DFA, respectively, except for hop matrices, for which the respective LOQs were 0.05 and 0.10 mg/kg. Results of an ILV demonstrated inter-laboratory reproducibility of the method.

The European multi-residue methods DFG S 19 and QuEChERS are unsuitable for the enforcement of this compound because the determination of the metabolite DFA is not possible – none of the extraction processes described in either of the methods would allow appropriate extraction of this molecule.

Method 01214 was developed as an *enforcement method* for animal matrices. It determines BYI 02960 and its metabolite DFA by HPLC-MS/MS. For quantification, matrix-matched standards were used. The LOQs were 0.01 mg/kg and 0.02 mg/kg for BYI 02960 and DFA, respectively, in all matrices. Results of an ILV demonstrated inter-laboratory reproducibility of the method.

DFA= Difluoroacetic acid

Description of the method

Residue analytical method 01330 (Schulte & Bauer, 2012; KIIA 4.3/01) was developed as an *EU enforcement method* for the determination of the residues of BYI 02960 (parent compound), and its metabolite DFA in/on plant materials.

The residues were extracted twice from 5 g of plant material with acetonitrile/water (4/1, v/v) with 2.2 mL/L formic acid. The materials tested included lettuce (head), rape (seed), orange (fruit), wheat (grain), and hop (cone), representing a wide variety of crops/crop types as requested by EU guidance. After dilution, an aliquot of the raw extract was filtered for measurement. The solution was analyzed by HPLC-MS/MS; residues were quantified against matrix-matched standards.

Results

Note:

The residues were extracted twice from 5 g of plant material with acetonitrile/water (4/1, v/v) with 2.2 mL/L formic acid. The materials tested included lettuce (head), rape (seed), orange (fruit), wheat (grain), and hop (cone), representing a wide variety of crops/crop types as requested by EU guidance. After dilution, *each* aliquot of the raw extract was filtered *for separate measurement of BYI 02960 and DFA. The solutions were analyzed by HPLC-MS/MS using either a C18-column (BYI 02960) or a ZIC®-HILIC SeQuant™ or a Hypercarb column (DFA)*; residues were quantified against matrix-matched standards.

Note:

The extraction efficiency of the residue method for the determination of the relevant residues of BYI 02960 in plant matrices, consisting of the parent compound and its metabolite DFA, was assured by choosing the same extraction procedures as used in the plant metabolism studies (cf. chapter 6.2.1 of the Annex II dossier).
In addition, an extraction efficiency study (see KIIA 4.3/04) was conducted using method 01304. As the extraction procedures for method 01330 are the same as for 01304, the results of the study prove satisfactory extraction efficiency with method 01330 in all matrices.The extraction efficiency was conducted in agreement with SANCO/825/00 rev. 8.1.

Conclusions

As DFA cannot be determined by DFG multi-residue method S 19 or by the QuEChERS procedure, a specific method, such as 01330, is suitable to determine the proposed enforcement residue definition for BYI 02960.

Method 01330 meets the necessary performance requirements to determine residues of BYI 02960 and its metabolite DFA in plant materials, with an LOQ of 0.01 mg/kg for BYI 02960 (0.05 in hops), and of 0.02 mg/kg for DFA (0.10 in hops). Results of an ILV showed that method 01330 fulfills the reproducibility requirements and is, therefore, applicable as an enforcement method.

Description of the method

Residue analytical method 01214 (Schulte & Bauer, 2012; KIIA 4.3/06) was developed as an EU *enforcement method* for the determination of the residues of BYI 02960 (parent compound), and its metabolite DFA in animal matrices.

The residues were extracted twice from 5 g of animal-based material with acetonitrile/water (4/1, v/v), with the addition of n-heptane in the cases of fat and milk. The materials tested included bovine muscle, liver, kidney, and milk; and chicken fat and egg, representing the variety of matrix types requested by EU guidance. After the addition of formic acid and dilution, an aliquot of the raw extract was filtered for measurement. After dilution, *each* aliquot of the raw extract was filtered for separate measurement of BYI 02960 and DFA. The solutions were analyzed by HPLC-MS/MS *using either a C18-column (BYI 02960) or a ZIC®-HILIC SeQuantTM or a Hypercarb column (DFA)*; residues were quantified against matrix-matched standards.~~The solution was analyzed by HPLC-MS/MS; residues were quantified against matrix-matched standards.~~

Extraction Efficiency

The extraction efficiency of the residue method for the determination of the relevant residues of BYI 02960 in animal matrices, consisting of the parent compound and its metabolite DFA, was assured by choosing the same extraction procedures as used in the livestock metabolism studies (cf. chapter 6.2.2 and 6.2.3 of the Annex II dossier). In addition an extraction efficiency examination was conducted as part of the poultry (KIIA 4.3/09) and cattle (KIIA 4.3/08) feeding studies. Aged residues in respective samples were analysed using procedures described in method RV-004-A11-04 and, in parallel, using the procedures described in the metabolism studies (cf. chapter 6.1 of Annex II dossier). As the extraction procedures for method RV-004-A11-04 are the same as for method 01214, the

results of the study prove satisfactory extraction efficiency with method 01214. The sample materials were eggs, fat, liver, and muscle in the poultry report, and kidney and milk in the ruminant report.

Blank value of untreated control samples:
From each sample material, two untreated control samples were examined. All residues of BYI 02960 and difluoroacetic acid (expressed as parent equivalents) were well below 30% of the corresponding LOQ level.

Ionisation type and MS/MS transition:
The experiments were performed on a triple-quadrupole mass spectrometer system, fitted with an electrospray interface operated in the positive ion mode for BYI 02960 and in negative mode for difluoroacetic acid under MRM conditions.

BYI 02960: ESI positive	1st MRM: 289 => 126 (quantification)
	2nd MRM: 289 => 90 (confirmatory)
DFA: ESI negative	1st MRM: 95 => 51

Results

Note

The extraction efficiency of the residue method for the determination of the relevant residues of BYI 02960 in animal matrices, consisting of the parent compound and its metabolite DFA, was assured by choosing the same extraction procedures as used in the livestock metabolism studies (cf. chapter 6.2.2 and 6.2.3 of the Annex II dossier).
In addition an extraction efficiency examination was conducted as part of the poultry (KIIA 4.3/09) and cattle (KIIA 4.3/08) feeding studies. Aged residues in respective samples were analysed using procedures described in method RV-004-A11-04 and, in parallel, using the procedures described in the metabolism studies (cf. chapter 6.1 of the Annex II dossier). As the extraction procedures for method RV-004-A11-04 are the same as for 01214, the results of the study prove satisfactory extraction efficiency with method 01214 in all matrices. The sample materials were eggs, fat, liver, and muscle in the poultry report, and kidney and milk in the ruminant report. The extraction efficiency was conducted in agreement with SANCO/825/00 rev. 8.1.

Conclusion

As DFA cannot be determined by DFG multi-residue method S 19 or by the QuEChERS procedure, a specific method, such as 01214, is valid for the determination of the proposed enforcement residue definition for BYI 02960.

Method 01214 meets the necessary performance requirements to determine residues of BYI 02960 and its metabolite DFA in animal matrices, with LOQs of 0.01 mg/kg for BYI 02960 and 0.02 mg/kg for DFA. Results of an ILV showed that method 01214 fulfils the reproducibility requirements and is, therefore, applicable as an enforcement method.

B.5.3 Analytical methods (residue) soil, water, air (IIA 4.4, IIA 4.5, IIA 4.7 ; IIIA 5.4, IIIA 5.6 to 5.8)

STUDY 9

Reference	:	Brumhard, B., Reineke, A.; 2009 (IIA 4.4/01)	GLP statement	:	Yes
Type of study	:	Analytical Method 01074 for the Determination of BYI 02960 in Soil using LC/MS/MS	Guidelines	:	SANCO/825/00 rev. 7
Year of execution	:	2009	Acceptability	:	Acceptable
Test substance	:	Flupyradifurone (BYI 2960)	Method reference	:	MR-07/337

Description of the method

Soil samples of 20 g are extracted in a microwave extractor with 40 mL of a mixture of acetonitrile (1:4; v/v). Then a subsample is centrifuged to remove fine particles of the soil. An aliquot of the sample solution was injected into the high performance liquid chromatograph and subjected to reversed phase chromatography coupled with tandem mass spectrometry (MS/MS) with electrospray ionisation. The MS/MS instrument was operated in the Multiple Reaction Monitoring mode (MRM). The pseudomolecular ions of the analytes ([M+H]+) were selected by the first quadrupole. These precursor ions were impulsed with nitrogen in the collision cell (second quadrupole) and the resulting fragment ions (product ions) were separated according to their m/z ratio in the third quadrupole. Two of these product ions per analyte were selected: one product ion (MRM-transition) serving for quantitation and the second for confirmation. The first MRM transition of BYI 02960 is the quantification ion with the mass 126 [m/z 126] and the second MRM transition is the confirmatory ion with the mass 99 [m/z 99].
The method was validated using a silt soil (Höfchen) and a sandy loam soil (Laacher Hof). Two different soils were used in order to assess a possible influence of different soil characteristics.

Variations in equipment or sample characteristics and/or deterioration of system performance may require slight modifications in the chromatographic or detector conditions listed in order to obtain adequate chromatographic peak shapes or sensitivity. Instrument parameters and mobile phase may be adjusted to improve separation from unexpected interfering peaks. Therefore, the given LC/MS/MS parameters listed (see following table) may require adaptation.

The detection by MS/MS was performed on a triple-quadrupole tandem mass spectrometer, equipped with a Turbo IonSpray (ESI) interface operated in positive ion mode and multiple reaction monitoring (MRM). Optimal collisionally-activated dissociation (CAD) conditions for fragmentation of the pseudomolecular ions of the analyte was applied with nitrogen as the collision gas.

For calculation of the concentrations, calibration curves were used. These curves were calculated automatically after each sequence run with the Applied Biosystem quantitation software Analyst (Version 1.4.1) using linear regression. Further calculations were performed using the software EXCEL 2003 (Office 2003®).

Results

Selectivity: The high selectivity of the method resulted from the HPLC separation in combination with MS/MS detection. Two MRM transitions were monitored for BYI 02960 (m/z 289 ⟶ 126 for quantitation and m/z 289 ⟶ 99 for confirmation). No signals / peaks interfering with the detection of the analyte were observed in extracts of untreated blank control specimens.

Linearity: For both mass transitions (m/z 289 ⟶ 126 and m/z 289 ⟶ 99) of BYI 02960 the correlation between the injected amount of substance and the detector response was linear for standards in matrix (both soil matrices: Höfchen and Laacher Hof) (l.Ong/L to 100 ng/L) corresponding to a concentration in soil of 2 to 200 p. µg/kg. The correlation coefficients of the 1/x weighted linear regression ranged from 0.9960 to 0.9973.

Untreated Control Samples: Apparent residues in control samples were below 0.3 **x** LOQ (1.5 H µg/kg) for BYI 02960.

Recovery Rates (Accuracy) and Precision (Repeatability): Recovery rates were determined at fortification levels of 5 µg/kg (= LOQ level), and 50 µg/kg. The lowest fortification level experimentally providing a mean recovery between 70 and 110% with a relative standard deviation of ≤ 20% per definition is the Limit of Quantitation (LOQ), provided that the blank values were below 30% of this level. Results are presented in the following tables.
As a measure for the precision of the method, the intra-laboratory repeatability (n = 5) is given as relative standard deviation (% RSD) for all sample materials at fortification levels of 5 and 50 µg/kg. The RSD of the repeatability tests at each recovery set ranged from 1.3 to 3.8 for the quantifier mass transition and from 1.5 to 3.3 % for the confirmatory mass transition.

Recoveries for BYI 02960 Quantifier Mass Transition (m/z 126) RSD: Relative Standard Deviation

Fortification [µg/kg]	Soil	Single values [%]					Mean [%]	RSD [%]
5.0	Höfchen	94	92	92	92	90	92	1.3
5.0	Laacher Hof	102	100	99	97	96	99	2.3
Mean of all 5.0 µg/kg single values							95	4.1
50.0	Höfchen	90	88	85	85	85	86	2.5
50.0	Laacher Hof	100	94	93	94	91	94	3.8
Mean of all 50.0 µg/kg single values							90	5.6
Mean of all Höfchen samples							89	3.8
Mean of all Laacher Hof samples							97	3.7
Overall mean							93	5.5

Recoveries for BYI 02960 Confirmatory Mass Transition (m/z 99) RSD: Relative Standard Deviation

Fortification [µg/kg]	Soil	Single values [%]					Mean [%]	RSD [%]
5.0	Höfchen	93	93	91	94	91	92	1.5
5.0	Laacher Hof	100	99	98	101	94	98	2.8
Mean of all 5.0 µg/kg single values							95	4.0

50.0	Höfchen	91	90	88	87	87	88	1.9
50.0	Laacher Hof	98	95	92	94	90	94	3.3
Mean of all 50.0 µg/kg single values							91	4.0
Mean of all Höfchen samples							90	2.7
Mean of all Laacher Hof samples							96	3.9
Overall mean							93	4.5

Limit of quantification (LOQ): The target limit of quantitation of the method is 5 µg/kg for BYI 02960. The target limit of detection of the method is 1.5 µg/kg for BYI 02960.

Conclusion

The method 01074 (report MR-07/337) was developed for determination of BYI 02960 in soil with target limit of quantitation of 5 µg/kg for BYI 02960. The method validation data are in compliance with the guideline requirements for residue data generation and enforcement. Thus, the method is the recommended enforcement method for monitoring of BYI 02960 residues in soil.

STUDY 10

Reference	:	Fargeix, G., Rosati, D.; 2012	GLP statement	:	Yes
Type of study	:	Analytical Method N°01213 for the Determination of Residues of BYI 02960 in Drinking and Surface Water by HPLC-MS/MS, parent and metabolites	Guidelines	:	SANCO/825/00 rev. 8
Year of execution	:	2012	Acceptability	:	Acceptable
Test substance	:	Flupyradifurone (BYI 2960)	Method reference	:	MR-12/022

Description of the method

BYI 02960 is determined by direct injection of filtered aliquot of sample into the high performance liquid chromatograph and subjected to reversed phase chromatography coupled with tandem mass spectrometry (MS/MS) with electrospray ionization, using positive ion mode without further clean-up. Concentrations are quantified using external matrix-matched standard solutions or standards in solvent: it is advised to quantify against matrix matched standards.
The MS/MS instrument is operated in the Multiple Reaction Monitoring mode (MRM). The pseudomolecular ions of the analytes ($[M+H]^+$ or any adducts) were selected by the first quadrupole. These precursor ions were impulsed with nitrogen in the collision cell (second quadrupole), and the resulting fragment (product ions) are separated according to their m/z ratio in the third quadrupole. Two of these product ions per analyte were selected: one product ion (MRM-transition) for quantitation and the second for confirmation. The first MRM transition of BYI 02960 is the quantification ion with the mass 126 [m/z 126] and the second MRM transition is the confirmatory ion with the mass 90 [m/z 90].

Variations in equipment or sample characteristics and/or deterioration of system performance may require slight modifications in the chromatographic or detector conditions listed in order to obtain adequate chromatographic peak shapes or sensitivity. Instrument parameters and mobile phase may be adjusted to improve separation from unexpected interfering peaks. Therefore, the given LC/MS/MS parameters listed (see following table) may require adaptation. Before running a batch of analyses, it is necessary to sufficiently equilibrate the LC column for the analysis of this compound. It is advised to inject 5 calibration points for equilibrium time.

Results

Selectivity/Specificity: The high selectivity of the method resulted from the HPLC separation in combination with MS/MS detection. Two MRM transitions were monitored for BYI 02960 (m/z 289 ➟ 126 for quantitation and m/z 289 ➟ 90 for confirmation). Therefore, the HPLC-MS/MS method is highly specific and an additional confirmatory method is not necessary. No signals / peaks interfering with the detection of the analyte were observed in extracts of untreated control samples. Apparent concentrations in control samples were below 0.3 x LOQ.

Linearity: The correlation between the injected amount of substance and the detector response was linear (1/x weighted) for aqueous Standard solutions ranging from 0.01 to 20 ug/L. The correlation coefficients were > 0.9998 for both MRM transitions.

Limit of Quantification (LOQ) and Limit of Detection (LOD): The LOQ for BYI 02960 is 0.05 ~~H~~ µg/L (rounded value) in surface water, and the LOD is 0.02 ~~u~~ µg/L.

Repeatability (Precision): As a measure for the precision of the method, the intra-laboratory repeatability is given as relative Standard deviation (% RSD) for surface water samples at fortification levels of 0.05 ~~u~~ µg/L and 0.5 ~~u~~ µg/L. The relative Standard deviation for the peak area of the quantification MRM was 5.2% (0.05 ug/L) and 2.5% (0.5 ~~u~~ µg/L).

Recovery Rates (Accuracy): Because of the direct measurement of fortified samples without separate extraction and clean-up steps it is not possible to determine recovery rates in a classical way and therefore, an estimate of the accuracy of the analytical technique was made by an assessment of the linearity of matrix calibration and by determination of the repeatability of sample analysis.

However, for additional demonstration of the reliability of the method, the validation samples were evaluated like recovery rates. Mean recoveries for each fortification level and the overall mean recoveries were within the 70 - 110% range for both MRM transitions. The results are shown in the following tables. All method validation data are in compliance with the guideline requirements for enforcement methods

Matrix Effects: The MS/MS detection of BYI 02960 was slightly affected by the matrix. Even if the results meet all guideline criteria on method validation, the method users are advice to use matrix matched standards because the recovery results are slightly closer to 100%, then.

Recoveries for BYI 02960 Quantifier Mass Transition (m/z 126); RSD = Relative Standard Deviation

Fortification [µg/L]	Matrix (measured by)	Single values [%]					Mean [%]	RSD [%]
0.05	Surface Water (matrix matched standards)	82	88	87	80	79	83	4.7
0.5		84	88	86	84	89	86	5.7
Mean		Mean single values					85	4.1
0.05	Surface Water (solvent standards)	76	82	81	75	74	78	4.7
0.5		81	84	83	73	77	80	5.7
Mean		Mean single values					79	5.1

Recoveries for BYI 02960 Confirmatory Mass Transition (m/z 90); RSD = Relative Standard Deviation

Fortification [µg/L]	Matrix (measured by)	Single values [%]					Mean [%]	RSD [%]
0.05	Surface Water (matrix matched standards)	94	94	94	90	90	92	2.4
0.5		81	82	79	84	84	82	2.6
Mean		Mean single values					87	6.7

Conclusion

All method validation data are in compliance with the guideline requirements for residue data generation and enforcement. Thus, the method is the recommended enforcement method for monitoring of BYI 02960 residues in drinking and surface water at 0.05 ug/L.

Guidelines & Limitations

None.

STUDY 11

Reference	:	Heinz, N., 2011	GLP statement	:	Yes
Type of study	:	Analytical methods for soil, air and water, Analytical Method for Determination in Air	Guidelines	:	SANCO/825/00 rev. 8.1
Year of execution	:	2011	Acceptability	:	Acceptable
Test substance	:	Flupyradifurone (BYI 2960)	Method reference	:	P 2419 G

Description of the method

Air sampling uses adsorption tubes, e.g. flame sealed glass tubes (OD: 8 mm, L: 100 mm) filled with two layers (front layer A: 100 mg, mesh size 20 and rear layer B: 50 mg, mesh size 40) of porous polymer (XAD: ORBO^{TM}-44, Supelco Cat. No. 20260-U), held in place by three glass wool plugs. Particles and aerosols are trapped by filtration or impact onto the adsorbent material. Both ends of sealed cartridges were opened and the fortification solution (10 µL) was dosed directly onto the front layer XAD adsorbent material (layer A, 100 mg adsorption material). The solvent was allowed to evaporate.

The sampling cartridges (including two blank control cartridges) were placed on a SPE station with the fortified layer A at the upper end. A laboratory air pump was attached to the pressure gauge of the station with a tube providing an air flow of 0.83 L/min. The SPE station was placed in a chamber where the air could be heated with a hot air fan. For air sampling under warm and humid conditions, warm air (heated by the fan in the partially closed cabinet) was passed over warm water before diverting the humidified air flow over the sampling cartridges. The water load of the air was calculated from the water loss in the round bottomed flask. The total relative humidity of the air passing through the sampling cartridges was obtained as the sum of the original humidity measured with a humidity sensor at the air inlet, plus the humidity added by evaporation.

After sampling of air (6 hours, i.e. a total air sampling volume of approx. 0.3 m^3), the cartridges were sealed with the provided plastic plugs. If not analyzed immediately, the cartridges may be stored at freezer temperature for up to 5 days. Storage stability was demonstrated as part of this study by storing two fortified cartridges (at LOQ level) for 5 days in a freezer at approx. -20°C. All solutions were stored in a refrigerator (at approximately ≤ 8 °C) when not in use.

The adsorbent is extracted three times with approx. 3 mL of acetonitrile. The extracts are combined and the volume is adjusted to 10 mL. Then a 100-µL or 50-µL aliquot of the raw extract is further diluted into water with 0.1% formic acid resulting in a final volume of 1.0 mL.

The analyte is determined by liquid chromatography with tandem mass spectrometric detection (LC-MS/MS), monitoring two parent-daughter ion transitions. The pseudomolecular ions of the analytes ($[M+H]^+$) were selected by the first quadrupole. These precursor ions were impulsed with nitrogen in the collision cell (second quadrupole) and the resulting fragment ions (product ions) were separated according to their m/z ratio in the third quadrupole. Two of these product ions per analyte were selected: one product ion (MRM-transition) serving for quantitation and the second for confirmation. The first MRM transition of BYI 02960 is the quantification ion with the mass 126 [m/z 126] and the second MRM transition is the confirmatory ion with the mass 99 [m/z 99]. These parameters are

given only as guidance and were established for the specimens of the present study, using the mentioned apparatus and analytical column.

Results

			107%		106%	
			104%		106%	

*: each five specimens included in calculation
Average CAir: Average fortified concentration of BYI 02960 in air.

Limit of quantification (LOQ): The method achieves a limit of quantification (LOQ) of 7 µg BYI 02960/m^3 air. Based on the detectability of 2.0 ng BYI 02960/mL and assuming a theoretical final volume of 100 mL and an air sample volume of approx. 0.3 m^3, the limit of detection (LOD) in the final extracts is estimated to be <0.7 µg/m^3.

Conclusion

The LC-MS/MS based analytical method (report no. P 2419 G) was developed for determination of BYI 02960 in air with target limit of quantitation of 7 µg BYI 02960/m³. The method validation data were in compliance with the guideline requirements for residue data generation and enforcement. Thus, the method is the recommended enforcement method for monitoring of BYI 02960 residues in

air.

Guidelines & Limitations

None.

B.5.4 Analytical methods (residue) for body fluids and tissues (IIA 4.8; IIIA 5.8)

A method of analysis for body fluids and tissues is not required, since the active substance is of low acute toxicity (GHS category 4).

B. 5.5 Evaluation and assessment

Analytical methods for analysis of the active substance as manufactured

The HPLC-method AM008809MP1 for the determination of Flupyradifurone (BYI 02960) in technical grade active substance can be used for determination of Flupyradifurone.

Analytical methods for formulation analysis

The HPLC method AM012609MF1for the determination of Flupyradifurone (BYI 2960) can be used for determination of flypyradifurone in the formulation Flupyradifurone (BYI 2960) SL 200.

Analytical methods for residue analysis

The following table gives an overview on the methods that may be used to monitor relevant flupyradifurone residues (comprising parent flupyradifurone and metabolite DFA) in plant and animal matrices.

Table 5.5.-1 Overview of monitoring methods in plant and animal material for flupyradifurone residues

Matrix group / crop group	Residue definition for monitoring	LOQ (mg/kg)	Methods[1]		
			Primary method	Confirmatory method	Independent lab validation
Dry commodities (high protein/high starch content)	BYI 02960, DFA	0.01 0.02	Method 01330 (LC-MS/MS)	yes	yes
Commodities with high water content	BYI 02960, DFA	0.01 0.02	Method 01330 (LC-MS/MS)	yes	yes
Commodities with high oil content	BYI 02960, DFA	0.01 0.02	Method 01330 M001 (LC-MS/MS)	yes	yes
Commodities with high acid content	BYI 02960, DFA	0.01 0.02	Method 01330 (LC-MS/MS)	yes	yes
Commodities which are difficult to analyse (hops)	BYI 02960, DFA	0.05 0.1	Method 01330 (LC-MS/MS)	yes	no
Milk	BYI 02960, DFA	0.01 0.02	Method 01214 (LC-MS/MS)	yes	yes
Eggs	BYI 02960, DFA	0.01 0.02	Method 01214 (LC-MS/MS)	yes	yes
Meat	BYI 02960, DFA	0.01 0.02	Method 01214 (LC-MS/MS)	yes	yes
Fat	BYI 02960, DFA	0.01 0.02	Method 01214 (LC-MS/MS)	yes	yes
Kidney	BYI 02960, DFA	0.01 0.02	Method 01214 (LC-MS/MS)	yes	yes
Liver	BYI 02960, DFA	0.01 0.02	Method 01214 (LC-MS/MS)	yes	yes

[1] BYI 02960: Two MRM transitions were measured (1st MRM for quantification: 289/126; 2nd MRM for confirmation: 289/90; ESI positive; C18 column)

DFA:	One MRM transition was measured using different HPLC conditions (ZIC-HILIC SeQuant column for quantification; Hypercarb column for confirmation; MRM: 95/51, ESI negative)

The ILV (independent lab validation) for hops (matrix difficult to analyze) is under preparation.

The submitted methods are suitable of monitoring in the relevant matrices.

Residues in body fluids and tissues

A method of analysis for body fluids and tissues is not required, since the active substance is of low acute toxicity (GHS category 4).

B.6 TOXICOLOGY AND METABOLISM

B.6.1 ABSORPTION, DISTRIBUTION, EXCRETION AND METABOLISM (TOXICOKINETICS) (ANNEX IIA 5.1)

Data requirement 2.1:

6-CNA cannot be regarded as a major metabolite in the rat studies (the level of 6.3%of the administered dose was obtained only in males treated with 200 mg/kg bw and was indiscriminately found in urine and faeces). Pending on the fate and behaviour section conclusion on 6-CNA calculated levels in groundwater, further toxicological data may be needed for this metabolite; see reporting table 2(1).

The toxicity of 6-CNA is assumed to be covered by the endpoints derived for the parent compound since 6-CNA and its succeeding metabolite BYI 02960-hippuric acid - which can be formed from 6-CNA only – represent a prominent portion in the urine of male rats.

The two metabolites, 6-CNA (0.4% to 6.0%) and BYI 02960-hippuric acid (1.1% to 10.4%) were detected in the urine of male and female rats after administration of [pyridinylmethyl-^{14}C]BYI 02960 at dose levels of 2 and 200 mg/kg bw, as well as in male rats after i.v. administration (female rats were not tested). The two metabolites represented a prominent portion in male rats, however showed lower concentrations in female rats.

	Proportion of dose detected in urine (% of total dose administered)[1]				
Compound	**Male, p.o. 2 mg/kg bw**	**Female, p.o. 2 mg/kg bw**	**Male, p.o. 200 mg/kg bw**	**Female, p.o. 200 mg/kg bw**	**Male, i.v. 2 mg/kg bw**

[1] Klempner, A.; 2012: [Pyridinylmethyl-^{14}C]BYI 02960 – Absorption, Distribution, Excretion, and Metabolism in the Rat, Report No. MEF 11/747, Document No. M-422210-01-1

In sum the metabolites represented 8% to 16% of the administered dose in male rats. Since BYI 02960-hippuric acid can be formed from 6-CNA only, the proportion of BYI 02960-hippuric acid can be added to the 6-CNA proportion to estimate the proportion of 6-CNA which was systemically available in the rat. When considering the two metabolites together, 6-CNA accounted for ≥ 10% of the dose administered dose in male rats after oral administration. Thus, 6-CNA was present in a sufficient concentration to contribute to the toxicological effects when testing the parent compound. Since the toxicological endpoints derived for parent compound were not dependent on the sex of the animals, it

can be concluded that the different metabolic behaviour of male and female rats had no influence on the toxicological profile.

In the fate section, 6-CNA was identified as a potential groundwater metabolite, however when calculating the worst case PECgw concentrations, no assessment of relevance has been triggered. The worst-case PECgw values were below the trigger concentration of 0.1 µg/L for all intended uses in Europe.

Results from expert consultation 2.1

6-CNA is mentioned as intermediate forming hippuric acid in the rat metabolic pathway. Adding hippuric acid to 6-CNA in the metabolism studies result in 6-CNA being a major rat metabolite in males, but not in females. It was agreed to sum up 6-CNA and hippuric acid for males and females. It was noted that in females both metabolites are not major rat metabolites, even when summing them up (at any dose level in the ADME studies). For 6-CNA, oral LD_{50} > 2000 mg/kg bw (less acutely toxic than the parent), no data are available for hippuric acid. This is not sufficient to conclude on the toxicity of the metabolites for the females, however for males, the experts agreed that the toxicity of the parent would cover the toxicity exerted by the metabolite 6-CNA.

B.6.1.1 Toxicokinetic studies – single dose, oral route in rats

Seven studies are summarised in this chapter; two with the pyridinylmethyl-^{14}C label (study 1 and 2), three with the furanone-^{14}C label (study 3-5), and two with the ethyl-1-^{14}C label (study 6 and 7). All are single dose studies.

Pyridinylmethyl-^{14}C Flupyradifurone

Furanone-4-^{14}C flupyradifurone

Ethyl-1-^{14}C flupyradifurone

Study 1 is an ADME-study in which male and female rats were orally administered with a single low (2 mg/kg/bw) or high dose (200 mg/kg bw) of flupyradifurone. Additionally, male rats were administered intravenously with flupyradifurone (2 mg/kg bw). The excretion via urine and faeces was investigated,

as well as the distribution in the plasma and the radioactivity concentration in organs and tissues after sacrifice. The metabolism was investigated in urine and faeces.

Study 2 is a quantitative whole body autoradiography study following a single oral dose of flupyradifurone (5 mg/kg bw) to male and female rats. At various time points the excretion of radioactivity was determined in urine, faeces and expired air, as well as the distribution in the plasma and the radioactivity concentration in the organs and tissues.

Study 3 is an ADME-study in which male and female rats were orally administered with a single dose of flupyradifurone (2 mg/kg bw). The excretion via urine and faeces was investigated, as well as the distribution in the plasma and the radioactivity concentration in organs and tissues after sacrifice. The metabolism was investigated in urine and faeces.

Study 4 is a quantitative whole body autoradiography study following a single oral dose of flupyradifurone (5 mg/kg bw) to male and female rats. At various time points the excretion of radioactivity was determined in urine, faeces and expired air, as well as the distribution in the plasma and the radioactivity concentration in the organs and tissues.

Study 5 is an organ metabolism study. Male and female rats were orally administered with a single dose of flupyradifurone (3 mg/kg bw) and sacrificed after 6 hours. The metabolism was investigated in urine, plasma, and in extracts of liver, kidney, muscle and fat tissues.

Study 6 is an ADME-study in which male rats were orally administered with a single dose of flupyradifurone (2 mg/kg bw). The excretion via urine and faeces was investigated, as well as the distribution in the plasma and the radioactivity concentration in organs and tissues after sacrifice. The metabolism was investigated in urine and faeces.

Study 7 is an organ metabolism study. Male and female rats were orally administered with a single dose of flupyradifurone (3 mg/kg bw) and sacrificed after 1, 6 or 24 hours. The metabolism was investigated in urine, plasma, and in extracts of liver, kidney, muscle and fat tissues.

As all single dose experiments revealed no indication of a potential for retention, accumulation and/or persistence of the administered radioactivity in organs or tissues. in line with paragraph 26 of the OECD Test Guideline 417, a repeated dose study was not considered necessary. This observation is supported by the low log P_{OW} of flupyradifurone of 1.2.

The different studies and their results are described in more detail below.

Study 1

Characteristics

Study design

The study was performed according to OECD Guideline 417. Male and female rats in groups of four rats/sex were administered orally by gavage a single dose of flupyradifurone suspended in 0.5% aqueous Tragacanth® (2 mL) at target dose levels of 2 mg/kg bw or 200 mg/kg bw. In addition, a group of four male rats was administered intravenously with a single dose of flupyradifurone in water (0.5 mL) at a dose level of 2 mg/kg bw (Table 6.1.1.-01). Flupyradifurone was radiolabelled with ^{14}C in the pyridinylmethyl bridge of the molecule.

* denotes the ^{14}C-label position

Urine and faeces were collected for the time range between dosing and sacrifice and the animals were sacrificed after 72 hours. Plasma levels of radioactivity were followed from each animal for 17 timepoints. Total radioactivity which included the test compound and metabolites was determined in excreta and in organs and tissues collected at sacrifice. Metabolism was investigated in urine and faeces.

Samples were analyzed by radio HPLC, radio TLC, LC-MS and NMR methods. Toxicokinetic parameters were calculated with the software TOPFIT version 2.0 where the dose normalized values were used for better comparison of the low tests among themselves and to the high dose tests.

Table 6.1.1.-01. Experimental groups for each dose level of [pyridinylmethyl-^{14}C]-flupyradifurone

Group no.	No. of animals	Route	Dose	Sacrifice time (hoiurs after last dose)
1	4 M	Oral (gavage)	2 mg/kg bw	72
2	4 F	Oral (gavage)	2 mg/kg bw	72
3	4 M	Oral (gavage)	200 mg/kg bw	72
4	4 F	Oral (gavage)	200 mg/kg bw	72
5	4 M	I.v.	2 mg/kg bw	72

Results

Recovery

The total recovery for the orally administered test was between approximately 97% and 103% of the administered dose in the excreta and the body of male and female rats. The total recovery was approximately 91% of the administered dose in the low dose intravenous administrated male rats.

Table 6.1.1.-02. Recovery of radioactivity in urine, gastrointestinal tract and the body following oral or intravenous dosing of [pyridinylmethyl-^{14}C] flupyradifurone

	% of the administered radioactivity				
	Male 2 mg/kg bw (oral)	Female 2 mg/kg bw (oral)	Male 200 mg/kg bw (oral)	Female 200 mg/kg bw (oral)	Male 2 mg/kg bw (i.v.)

Balance	**98.73**	**97.63**	**102.60**	**96.57**	**91.11**

Absorption

The bioavailability factor was determined from plasma kinetics of the oral and i.v. low dose test with male rats (group 1 and 5). A bioavailability factor of F = 0.93 was obtained demonstrating that the orally administered test compound was almost completely bioavailable. This high bioavailability factor was confirmed by the high radioactivity (76% to 90%) detected in the urines and the bodies without

GIT of male and female rats. The absorption started immediately after dosing as could be seen from the quick increase of radioactivity in plasma.

Distribution and plasma kinetics

Flupyradifurone was quickly absorbed and distributed. The C_{max} was reached at approximately 1 hour after administration at the low dose tests (Figure 6.1.1.-01). In the high dose tests C_{max} was reached approximately 2 hours for the males and at approximately 4 hours for the females. The plasma concentrations declined to 50% of C_{max} within 4 - 8 hours and to 1 - 2% of C_{max} within 24 hours in the low dose test with both male and female rats. In the high dose test the plasma concentrations declined to 50% within 8 to 24 hours and to 1-2% of C_{max} after 48 hours. At time of sacrifice, 72 hours after administration, the plasma concentrations were below or around LOQ for the low dose animals and approximately 0.5% of C_{max} for the high dose animals. An overview of all important results of the TOPFIT analysis is presented in table 6.1.1.-04.

Figure 6.1.1.-01.Comparison of dose normalised plasma curves following oral administration of low and high doses of [pyridinylmethyl-^{14}C] flupyradifurone to male and female rats

Table 6.1.1.-04. Pharmacokinetic parameters and calculation of the bioavailability of [pyridinylmethyl-^{14}C] flupyradifurone after oral administration to male and female rats, and after i.v. administration to male rats

	Male 2 mg/kg bw (oral)	Female 2 mg/kg bw (oral)	Male 200 mg/kg bw (oral)	Female 200 mg/kg bw (oral)	Male 2 mg/kg bw (i.v.)
t_{max} measured [h]	1.0	1.0	2.0	4.0	0.67
t_{max} calculated [h]	1.13	1.15	2.23	3.35	0.38
C_{max} measured values	0.878	0.937	0.497	0.578	1.04
C_{max} calculated (fitted) values	0.880	0.929	0.500	0.582	1.0400
$t_{1/2\ abs}$ [h]	0.21	0.17	0.13	0.17	0.06
$t_{1/2\ elim\ 1}$ [h]	3.9	3.0	3.6	8.1	3.8
$AUC_{0-\infty}$ [mg/L·h]	6.10	7.96	6.16	9.73	6.55
MRT_{tot} [h]	6.07	6.69	8.70	13.10	5.71

The biokinetic parameters were comparable in the three low dose tests. Only the AUC value for females of the low dose test was approx. 1.3 times higher than for males, which is related to the slightly broader peak maximum of the plasma curve of female rats. In the high dose tests, the AUC

value for males was proportional to the dose. For females, the AUC value of the high dose test was approx. 1.2 times higher than for the low dose test with females and approx. 1.6 times higher than for the high dose test with males. According to the broader maximum of the plasma curve of female rats in the high dose test, C_{max} was reached later than in males (approx. 4 hours instead of 2 hours). The biokinetic model confirmed a fast absorption phase in all tests with short half-lives of max. 0.2 hours followed by a short elimination phase with half-lives of about 3 – 4 hours. Only females in the high dose test showed a slightly longer elimination phase with a half-life of about 8 hours. The mean residence times in the low dose tests were in the range of approx. 6 – 7 hours. The mean residence times were slightly longer in the high dose tests and amounted to about 9 hours for males and 13 hours for females.

Excretion

Approximately 76% of the administered dose was detected in the urine of male rats, for low or high oral dose and low i.v. dose. For females 90% and 86% was detected in urine in the low and high dose, respectively. The major route of excretion is therefore by urine. Faecal excretion accounted for ca. 7 - 10% of the given dose in females and was slightly higher for males, where between approximately 15 to 26% was excreted with the faeces. Also the major part of faecal residues, approx. 89 - 92% of the radioactivity in faeces in the low dose tests and approximately 47% (females) and 77% (males) in the high dose tests, was excreted within the first day after treatment and was almost complete 48 hours post administration. The cumulative excretion results are summarized in Table 6.1.1-05.

Table 6.1.1.-05. Cumulative excretion of radioactive residues via urine and faeces after oral administration of [pyridinylmethyl-^{14}C] flupyradifurone to male and female rats, and after i.v. administration to male rats

Radioactive residues in organs and tissues at sacrifice

Approximately 0.1 - 0.3% of the total dose was detected in the body of male and female rats at the time of sacrifice 72 hours after oral and i.v. administration; only a trace amount of 0.01 - 0.09% was found in the GIT. The residual concentrations of radioactivity were low in the low dose tests and ranged from 0.0007 to 0.0175 mg/kg. The highest concentrations were detected in blood cells and the GIT, and in the eyes of female rats. But basically, levels for most organs and tissues were very similar and in the range of approx. 0.001 to 0.007 mg/kg. The residual concentrations of the high dose tests were almost dose proportional and ranged from 0.0859 to 2.345 mg/kg. The highest concentrations were also detected in blood cells and the GIT, as well as in the eyes of female rats. For most organs and tissues the residue concentrations in males were slightly higher as compared to females.
The equivalent concentrations of the residual radioactivity in organs and tissues at sacrifice are presented in Table 6.1.1-06.

Table 6.1.1.-06. Total radioactive residues in organs and tissues at sacrifice after administration of [pyridinylmethyl-^{14}C] flupyradifurone to male and female rats.

Metabolites in urine and faeces

Flupyradifurone was metabolized to numerous metabolites, most of them being minor ones. The parent compound was the predominant part of the radioactivity in urine of male and female rats. In faeces samples of male rats, the metabolite BYI 02960-OH was more prominent than the parent compound. Two metabolites, BYI 02960-6-CNA and BYI 02960-hippuric acid were also prominent in male rats but not in females. All other identified and characterised metabolites represented a minor part of the dose. The metabolic profiles in urine and faeces were very similar for both sexes but male rats showed a higher rate of metabolite formation as compared to female animals. The metabolism results are summarized in the Table 6.1.1-07.

Table 6.1.1.-07. Identified metabolites in urine and faeces after administration of [pyridinylmethyl-^{14}C] flupyradifurone to male and female rats.

Acceptability

The study was considered acceptable.

Conclusions

Flupyradifurone was completely absorbed in all test as demonstrated by the high bioavailability after oral administration and by the high amounts of radioactivity detected in urine and the body without GIT at sacrifice. Excretion of radioactivity was fast and mainly renal. Female rats showed slightly higher renal excretion rates of approx. 86% and 90% of the administered dose than males with approx. 76% of the dose. The major part of the dose (>84%) was excreted within 24 hours after treatment. The parent compound, three major and five minor metabolites were identified in all samples. Identification rates were high and amounted to approx. 83% - 94% of the given dose. The metabolic transformation of flupyradifurone was principally oxidative in nature and took place at least at 3 different structural positions.

group size	:	8 males + 1 control, 8 females + 1 control			

Study design

The study was performed according to OECD Guideline 417. Male and female rats in groups of eight rats were administered orally by gavage a single dose of [pyridinylmethyl-^{14}C]-flupyradifurone at target

dose levels of 5 mg/kg bw after about 16 hours of fasting. A control animal of each gender was treated with 5 mg/kg bw non-radiolabelled flupyradifurone (Table 6.1.1.-08).

* denotes the ^{14}C-label position

After administration of [pyridinylmethyl-^{14}C]-flupyradifurone, the rats were kept individually, which allowed for separate and quantitative collection of urine, faeces, and expired air. Urine was collected separately for each animal in intervals of 1h, 4 h, 8 h, 24 h, and every 24 h until 168 h. The radioactivity was determined by LSC. The faeces samples were collected every 24 h separately for each animal. The radioactivity was determined by combustion/LSC. Carbon dioxide and other volatiles from expired air were collected from four male and four female animals for the time ranges 0 - 24 h and 24 - 48 h. At sampling, the exact volume was determined, from which an aliquot was taken for the determination of radioactivity by LSC.

One animal of each gender was sacrificed using carbon dioxide at 1, 4, 8, 24, 48, 72, 120, and 168 hours post administration. The control animals were sacrificed 4 hours after dosing. The distribution of total radioactivity to, and elimination from blood, organs and tissues was analyzed qualitatively and quantitatively by whole-body auroradioluminography.

Table 6.1.1.-08. Experimental groups for each dose level of [pyridinylmethyl-^{14}C]-flupyradifurone

Group no.	No. of animals	Route	Dose	Sacrifice time (hoiurs after last dose)
1	8 M	Oral (gavage)	5 mg/kg bw	1, 4, 8, 24, 48, 72, 120, 168
	1 M (control)	Oral (gavage)	5 mg/kg bw	4
2	8 F	Oral (gavage)	5 mg/kg bw	1, 4, 8, 24, 48, 72, 120, 168
	1 F (control)	Oral (gavage)	5 mg/kg bw	4

Results

Distribution

For almost all organs and tissues, maximum concentrations were reached at one hour after administration. At t_{max}, the organ/blood concentration ratios for many organs and tissues were in a range of approx. 0.8 - 1.2, *i.e.* the radioactivity concentration in these organs and tissues was in the range of ± 20% of the concentration in blood. The radioactivity administered with [pyridinylmethyl-^{14}C] flupyradifurone was rapidly cleared from the blood and distributed to the entire body, preferably to

those organs or tissues responsible for metabolism (liver), excretion (kidney) and secretion (*e.g.* adrenal, thyroid, Harderian and salivary glands). The lowest values were measured for perirenal fat, the spinal cord, and brain.

The equivalent concentrations in blood, organs and tissues declined rapidly following approximately first order kinetics in the time range between 1 and 48 hours. At 24 hours after dosage, the concentrations in blood and also in most other tissues were below 5% of the maximum concentration, except nasal mucosa and vitreal body with approx. 7 - 11% of CEQ_{max}. At 48 hours after administration, the concentrations had declined to below 1% of the maximum concentration, except vitreal body and nasal mucosa which exhibited approx. 3 - 8% of $CEQ_{max.}$ After seven days, the equivalent concentrations in almost all organs and tissues had fallen below the limit of quantification. Very low concentrations of radioactivity were still detectable in blood, renal medulla, liver, and lung. For all these organs, the concentration was lower than in the blood. The results are summarized in Table 6.1.1.-09 (male rats) and Table 6.1.1.-10 (female rats) .

Excretion

[Pyridinylmethyl-^{14}C] flupyradifurone was excreted rapidly and completely within ca. 48 hours. The major part of the radioactivity (up to 85% in male and up to 93% in female rats) was excreted with urine and the minor part (about 20% for male and ca. 8% for female rats) with the faeces. One day after dosing >90% of the dose was excreted and the excretion was almost complete after two days. The expiration of ^{14}C-carbon dioxide and other ^{14}C-labelled volatiles was tested with male and female animals for a test period of 48 hours. Less than 0.1% of the administered dose was expired during the sampling period. This demonstrates the stability of the pyridinylmethyl-^{14}C label with regard to possible

formation of volatile products. The excretion behavior is summarized in Table 6.1.1.-11 (male rats) and Table 6.1.1.-12 (female rats).

Acceptability

The study was considered acceptable.

Conclusions

[pyridinylmethyl-^{14}C] flupyradifurone was readily absorbed from the gastrointestinal tract of male and female rats after single oral administration of 5 mg/kg bw. The radioactivity was distributed throughout the body immediately after administration but with a clear preference to liver and kidney. The radioactivity was quickly excreted, mainly with the urine (>80%). More than 90% of the administered dose was excreted within 24 hours, and 95% to 100% after 48 hours. Based on the results of this study, any accumulation or significant retention of [pyridinylmethyl-^{14}C] Flupyradifurone in male and female rats can be excluded.

group size	:	4/sex			

Study design

The study was performed according to OECD Guideline 417. Male and female rats in groups of four rats per sex were administered orally by gavage a single dose of flupyradifurone suspended in 0.5% aqueous Tragacanth® (2 mL) at target dose levels of 2 mg/kg bw (Table 6.1.1-13). Flupyradifurone was radiolabelled with ^{14}C in the 4-position of the furanone ring of the molecule.

* denotes the ^{14}C-label position

Urine and faeces were collected for the time range between dosing and sacrifice and the animals were sacrificed after 168 hours. Plasma levels of radioactivity were followed from each animal for 23 timepoints. Total radioactivity which included the test compound and metabolites was determined in excreta and in organs and tissues collected at sacrifice. Metabolism was investigated in urine and faeces.

Samples were analyzed by radio HPLC, radio TLC, LC-MS and NMR methods. Toxicokinetic parameters were calculated with the software TOPFIT version 2.0.

Table 6.1.1.-13 Experimental groups for each dose level of [Furanone-4-^{14}C] flupyradifurone

Group no.	No. of animals	Route	Dose	Sacrifice time (hoiurs after last dose)
1	4 M	Oral (gavage)	2 mg/kg bw	168

2	4 F	Oral (gavage)	2 mg/kg bw	168

Results

Recovery

The total recovery for the orally administered test was approximately between 96% and 102% of the administered dose in the excreta and the body of male and female rats.

Table 6.1.1-14. Recovery of radioactivity in urine, faeces, gastrointestinal tract and the body following a single oral dose of [furanone-4-^{14}C] flupyradifurone (2 mg/kg bw)

	% of administered dose	
	Male	**Female**
Faeces	16.59	10.38
Urine	78.96	91.37
Sum of excreta	**95.56**	**101.0**
Body without GIT	0.48	0.17
GIT	0.02	0.01
Total Body	**0.49**	**0.18**
Balance	**96.05**	**101.90**

Absorption

The total amount of absorbed [furanone-4-^{14}C] flupyradifurone is at least 79% for males and 91% for females since the sum of the dose in urine and body excluding GIT is 79% and 91%, respectively. The absorption started immediately after dosing as could be seen from the quick increase of radioactivity in plasma.

Distribution and plasma kinetics

[Furanone-4-^{14}C] flupyradifurone was quickly absorbed and distributed. The C_{max} was reached at approximately 1.5 hour after administration. The plasma concentrations declined to 50% of C_{max} within 8 hours and to 2 - 3% of C_{max} within 24 hours for both male and female rats. At time of sacrifice, 168 hours after administration, the plasma concentrations were below LOQ for both male and female rats. Male rats exhibited about two-fold higher concentrations than females in the time range ≥48 hours. This behavior is probably caused by higher amounts of [furanone-4-^{14}C] flupyradifurone metabolized to C1 and C2 fragments being incorporated into biomolecules or exhaled as $^{14}CO_2$ in males. At the time of sacrifice, 168 hours after administration, the plasma concentration was below LOQ for both male and female animals (Table 6.1.1.-15).

The mean values of total radioactivity were used for a toxicokinetic modeling using the TOPFIT software. A good fit could only be achieved with a three compartment model due to the obvious biphasic nature of the plasma curves. The modeling was performed for the time range between 0 and 152 hours for males and 0 to 72 hours for females. The biokinetic parameters were very similar for both sexes but females exhibited a somewhat shorter mean residence time than males. The area under curve (AUC) was 16.0 mg/kg*h for male and 18.2 mg/kg*h for female rats. The model confirmed a biphasic decline of plasma radioactivity with a short first half life of elimination of approximately 3 hours which is probably mainly attributable to the elimination of the parent compound and a significantly longer second half-life of about 53 hours, probably related to the incorporation of radioactivity into biomolecules. The corresponding concentration-time curves of the modeled and the measured data are shown in Figure 6.1.1.-02 below.

Figure 6.1.1.-2. Timecourse of radioactivity in the plasma following a single oral dose of [furanone-4-^{14}C] flupyradifurone (2 mg/kg bw). (upper curve: male rats; lower curve: female rats)

Excretion

Approximately 79% and 91% of the administered dose was detected in the urine of male and female rats, respectively, and about 75% and 87% was excreted within 24 hours. The major route of excretion is therefore by urine, and is somewhat higher in female rats compared to male rats. Faecal excretion accounted for about 17% of the given dose in male rats, and the major part of faecal residues, approximately 15% of the dose, was excreted within the first 24 hours. In female rats approximately 10% of the dose is found in faeces where about 9% of the dose is excreted in the first 24 hours. The cumulative excretion results are summarized in Table 6.1.1-16.

Table 6.1.1.-16. Cumulative excretion of radioactive residues via urine and faeces after oral administration of [furanone-4-^{14}C] flupyradifurone to male and female rats

Radioactive residues in organs and tissues at sacrifice

Approx. 0.5% of the dose was detected in the body of male rats at sacrifice 168 hours after oral administration; only a very minor amount of 0.02% was found in the GIT. Residual concentrations of radioactivity were in the range of 0.0025 to 0.0336 mg/kg. The lowest concentration was detected in the plasma and the highest value in the thyroid. But basically, levels for most organs and tissues were very similar and in the range of approx 0.005 to 0.01 mg/kg. For female rats, approx. 0.2% of the dose was still present in the body at sacrifice and only a negligible proportion of 0.01% in the GIT. Residual concentrations of radioactivity were in the range of 0.0012 to 0.0131 mg/kg. The lowest concentration was detected in the plasma and the highest value in the thyroid. As for males, levels for most organs and tissues were very similar and in the range of approx 0.002 to 0.005 mg/kg. For most organs and tissues the residues in males were 2 - 3 times higher as compared to females. This difference is also very likely caused by the higher rate of incorporation of radioactivity into biomolecules

The equivalent concentrations of the residual radioactivity in organs and tissues at sacrifice are presented in Table 6.1.1.-17.

Table 6.1.1.17. Total radioactive residues in organs and tissues at sacrifice after oral administration of [furanone-4-^{14}C] flupyradifurone to male and female rats.

Metabolites in urine and faeces

Flupyradifurone was metabolized to approximately 20 metabolites. The parent compound represented the predominant part of the radioactivity in urine while in faeces the amounts of the metabolite BYI 02960-OH were more or less similar. All other identified and characterised metabolites represented a minor part of the dose. The metabolic profiles in urines and faeces were very similar for both sexes but male rats exhibited a higher rate of metabolite formation as compared to female animals. A summary of the distribution of the parent compound and metabolites in the excreta is provided in Table 6.1.1-18.

Table 6.1.1.-18. Amounts of metabolites in the excreta of rats after administration of [furanone-4-^{14}C] flupyradifurone

Compound	% of the total dose administered

* unknown 1 from urine of male rats was further characterized by TLC analysis of the isolated metabolite fraction.

Acceptability

The study was considered acceptable.

Conclusions

Flupyradifurone was completely absorbed as demonstrated by the high amounts of radioactivity detected in urine and the body without GIT at sacrifice (>79% of the administered dose). Excretion of radioactivity was fast and mainly renal. Female rats showed a slightly higher renal excretion rate (91%) than male rats (78%). The major part of the dose (>89% for males and >96% for females) was excreted within 24 hours after treatment. The parent compound, one major and six minor metabolites were identified in all samples. Identification rates were high and amounted to >90% of the given dose. The metabolic transformation of flupyradifurone was principally oxidative in nature and took place at least at 3 different structural positions. Basically, male rats showed a higher rate of metabolism with only ca. 55% of unchanged parent compound found in excreta whereas 76% of unchanged BYI 02960 was found in the excreta of female rats. But the metabolic patterns were very similar in males and females.

Study 4

Study design

The study was performed according to OECD Guideline 417. Male and female rats in groups of eight rats were administered orally by gavage a single dose of [furanone-4-^{14}C] flupyradifurone at target dose levels of 5 mg/kg bw after ca. 16 hours of fasting. A control animal of each gender was treated with 5 mg/kg bw non-radiolabelled flupyradifurone (Table 6.1.1.-19).

* denotes the ^{14}C-label position

After administration of [furanone-4-^{14}C] flupyradifurone, the rats were kept individually, which allowed for separate and quantitative collection of urine, faeces, and expired air. Urine was collected separately for each animal in intervals of 1, 4, 8, 24 hours, and every 24 hours until 168 hours. The radioactivity was determined by LSC. The faeces samples were collected every 24 hours separately for each animal. The radioactivity was determined by combustion/LSC. Carbon dioxide and other volatiles from expired air were collected from four male and four female animals for the time ranges 0 - 24 h and 24 - 48 h. At sampling, the exact volume was determined, from which an aliquot was taken for the determination of radioactivity by LSC.
One animal of each gender was sacrificed using carbon dioxide at 1, 4, 8, 24, 48, 72, 120, and 168 hours post administration, respectively. The control animals were sacrificed 4 hours after dosing. The distribution of total radioactivity to, and elimination from blood, organs and tissues was analyzed qualitatively and quantitatively by whole-body autoradioluminography.

Table 6.1.1.-19. Experimental groups for each dose level of [furanone-4-^{14}C] flupyradifurone

Group no.	No. of animals	Route	Dose	Sacrifice time (hoiurs after last dose)

	1 M (control)	Oral (gavage)	5 mg/kg bw	4
2	8 F	Oral (gavage)	5 mg/kg bw	1, 4, 8, 24, 48, 72, 120, 168
	1 F (control)	Oral (gavage)	5 mg/kg bw	4

Results

Distribution

The distribution in male and female rats was fast; maximum concentrations were reached at one hour after administration. The maximum concentrations in several organs and organs, *i.e.* liver, kidney, brown fat, myocardium, almost all glandular organs and the olfactory bulb were higher than in blood. The administered dose of [furanone-4-^{14}C] flupyradifurone was rapidly absorbed and distributed to the entire body, preferably to those organs or tissues that are responsible for metabolism. The equivalent concentrations in blood, organs and tissues declined following a biphasic kinetics showing a fast

phase from 1 to 24 hours (females: 1 to 48 hours) and a slower decline from 24 to 168 hours (female: 48 to 168 hours). After 168 hours the radioactivity concentrations in blood and all organs and tissues had declined significantly but were still higher in almost all of the organs than in blood. Slightly lower values were detected in the skeleton muscle, myocardium, lung, pancreas, pineal and vitreal body. Highest values were in perirenal fat (males), uterus and nasal mucosa. For all these organs, the concentration was lower than in the blood. The results are summarized in Table 6.1.1.-20 (male rats) and Table 6.1.1.-21 (female rats) .

Excretion

[furanone-4-^{14}C] flupyradifurone was excreted rapidly and completely within ca. 48 hours. The major part of the radioactivity (up to 81% in male and up to 88% in female rats) was excreted with urine and the minor part (about 16% for male and about 7% for female rats) with faeces. The exhalation of ^{14}C-carbon dioxide was tested with male and female animals for a period of 48 hours. Between 2.02% and 3.25% (males) and 0.50% and 0.96% (females) of the administered radioactivity was exhaled during this period. This demonstrated that for a small portion of the dose (higher in males than in females) the furanone ring of the molecule obviously underwent biotransformation to C1- and C2-fragments and the terminal product $^{14}CO_2$.

Table 6.1.1.-22: Excretion of radioactivity in urine, faeces and expired air of male rats after a single oral administration of [furanone-4-^{14}C] flupyradifurone (5 mg/kg bw)

Acceptability

The study was considered acceptable.

Conclusions

[furanone-4-^{14}C] flupyradifurone was readily absorbed from the gastrointestinal tract of male and female rats and evenly distributed throughout the rat bodies immediately after the single oral administration of 5 mg/kg bw. [furanone-4-^{14}C] flupyradifurone related radioactivity was rapidly cleared from blood and distributed primarily to those organs or tissues that are responsible for metabolism, excretion and secretion. The excretion of radioactivity *via* urine and faeces was almost completed two days after administration with more than 80% of the dose detected in the urine of both sexes.
The detection of $^{14}CO_2$ in the exhaled air during a sampling period of 48 hours (up to 3.25% in male and 0.96% in female rats) demonstrated that for a small portion of the dose the furanone ring obviously underwent biotransformation to C1- and C2-fragments and the terminal product $^{14}CO_2$. Peak

concentrations of radioactivity for almost all organs and tissues were reached already one hour after dosing. From then onwards, the concentrations declined following a biphasic kinetics. The second slower decline phase, which started after 24 hours in males and after 48 hours in females, is probably due to the formation of small carbon units (C1- or C2-fragments) that entered the carbon pool used for the biosynthesis of endogenous compounds. This is presumably also the reason that at the end of the test (day 7) low radioactive residues were still measured in almost all organs and tissues.
The terminal residues were always by a factor of 1.4 to 4.7 higher in males than in females. A similar ratio of approx. 3 was also found for the formation of $^{14}CO_2$ in males as compared to females. The reason is probably a gender specific quantitative difference in metabolism leading to more C1- and C2-fragments and also a higher incorporation of these components into the endogenous carbon pool. From the results of this study, any significant accumulation or retention of [furanone-4-^{14}C]BYI 02960 in male and female rats can be excluded.

group size	:	4/sex			

Study design

The study was performed according to OECD Guideline 417. Male and female rats in groups of four rats were administered orally by gavage a single dose of flupyradifurone at target dose levels of 3 mg/kg bw (Table 6.1.1.-24). Flupyradifurone was radiolabelled with ^{14}C in the 4-position of the furanone ring of the molecule.

* denotes the ^{14}C-label position

Urine and faeces were collected for the time range between dosing and sacrifice, the animals were sacrificed after 6 hours. Total radioactivity which included the test compound and metabolites was determined at sacrifice in urine, plasma, liver, kidney, muscle (leg) and fat (perirenal). The metabolism was investigated in urine and plasma samples and in extracts of liver, kidney, muscle and fat. Samples were analyzed by radio HPLC, radio TLC, LC-MS and NMR methods.

Table 6.1.1.-24. Experimental groups for each dose level of [furanone-4-^{14}C] flupyradifurone

Group no.	No. of animals	Route	Dose	Sacrifice time (hoiurs after last dose)
1	4 M	Oral (gavage)	5 mg/kg bw	6
2	4 F	Oral (gavage)	5 mg/kg bw	6

Results

Recovery

The total recovery for the orally administered test was between approximately 98% and 101% of the administered dose in urine, organs and tissues, skin and the combined GIT and faeces samples of male and female rats (Table 6.1.1.-25). In male and female rats, approx. 40% of the dose was detected in organs and tissues, the highest amount was found in the residual carcass (approx. 24 - 27%), followed by skin, liver, muscle, kidney, and fat for which the lowest values were measured.(approx. 0.06 - 0.09%). For the 0 - 6 h collection period, the renal excretion in female rats was by a factor of approx. 1.17 higher than in male rats.

Table 6.1.1.-25: Recovery of radioactivity in urine, plasma and organs 6 h after a single oral dose of [furanone-4-^{14}C] flupyradifurone (3 mg/kg bw)

Balance	**100.60**	**98.09**

Metabolism:

Table 6.1.1.-26 shows the amount of flupyradifurone and its metabolites after six hours in urine of male and female rats as percentage of the given dose. In urine, the parent compound was the dominating radioactive component (approximately 22% of the dose in males and 38% in females). The concentrations of radioactivity in plasma can be found in Table 6.1.1.-27, in liver in Table 6.1.1.-28, in kidney in Table 6.1.1.-29, in muscle in table 6.1.1.-30 and in fat tissue in table 6.1.1.-31. The highest radioactivity concentrations were detected in the liver (approx. 2.9 mg/kg for both sexes) and kidney (approx. 2.7 mg/kg for males and 4.3 mg/kg for females) as the main metabolic and excretory organs. The residue concentrations for plasma and the other tissues were comparable for both sexes and ranged from approx. 0.6 mg/kg for the perirenal fat to approx. 1.5 mg/kg for the leg muscle. Six hours after administration [furanone-4-^{14}C] flupyradifurone was only incompletely metabolized. Metabolic reactions took place at least at 3 different structural positions of the molecule. The majority of the radioactive residues were identified (approximately 89% - 100% in plasma and in extracts of organs and tissues as well as ≥ 88% of radioactivity in urine samples). In all samples of plasma, organs and tissues the parent compound was the by far largest component accounting for more than 72% of the total radioactivity. None of the identified metabolites accounted for more than 12% of the total radioactivity. The metabolism was qualitatively similar in male and female rats, but with quantitative differences. The degradation of the parent compound to the different metabolites was significantly higher in male as compared to female rats.

Acceptability

The study was considered acceptable.

Conclusions

The distribution of the radioactivity within the organs and tissues (*i.e.* blood, liver, kidney, muscle and fat) showed a distinctive preference for liver and kidney as the main metabolizing and excretory organs. The metabolic transformation of flupyradifurone was principally oxidative in nature and took place at least at 3 different structural positions of the molecule. The metabolic pattern was in good accordance with that obtained from the corresponding ADME rat studies. With regard to the extent of metabolism, a clear sex difference was observed since it was higher in male than in female rats, *i.e.* the metabolic degradation of the parent compound was much less pronounced in females.

Study 6

Species	:	Rat Wistar Hsd/Cpb: WU	acceptability	:	acceptable
group size	:	4 male			

Study design

The study was performed according to OECD Guideline for testing chemicals 417. Four male rats were administered orally by gavage a single dose of [Ethyl-1-^{14}C] flupyradifurone suspended in 0.5% aqueous Tragacanth® (2 mL) at target dose level of 2 mg/kg bw. Flupyradifurone was radiolabelled with ^{14}C in the 1-position of the ethyl side chain:

* denotes the position of the ^{14}C-label

Urine and faeces were collected for the time range between dosing and sacrifice and the animals were sacrificed after 72 hours (Table 6.1.1.-32). Plasma levels of radioactivity were followed from each animal for 12 time points. Total radioactivity which included the test compound and metabolites was determined in excreta and in organs and tissues collected at sacrifice. Metabolism was investigated in urine and faeces. Samples were analyzed by radio HPLC, radio TLC, LC-MS and NMR methods. Toxicokinetic parameters were calculated with the software TOPFIT version 2.0.

Table: 6.1.1.-32. Experimental groups for each dose level of [Ethyl-1-^{14}C] flupyradifurone

Group no.	No. of animals	Route	Dose	Sacrifice time (hoiurs after last dose)
1	4 M	Oral (gavage)	2 mg/kg bw	72

Results

Recovery

The results in percent of the given dose in expired air, urine, faeces, organs and tissues at sacrifice are summarized in Table 6.1.1.-33. The total recovery for the orally administred test was approximately 100%.

Table 6.1.1.-33. Recovery of radioactivity in urine, faeces, gastrointestinal tract and the body following a single oral dose of [ethyl-1-^{14}C] flupyradifurone (2 mg/kg bw)

	% of given dose
Expired air	0.20
Faeces	13.51
Urine	82.24
Sum of excreta	**95.95**
Body excluding GIT	3.19
GIT	0.73
Total Body	3.92
Balance	**99.86**

Absorption

[Ethyl-1-^{14}C] flupyradifurone was almost completely absorbed in male rats. The absorption rate was at least 85% because >82% of the dose was detected in urine and >3% in the body without GIT. The absorption commenced immediately after dosing as can be seen from the quick increase of radioactivity in plasma micro samples (Table 6.1.1-34).

Table 6.1.1.-34. Timecourse of radioactivity in the plasma following a single oral dose of [ethyl-1-^{14}C] flupyradifurone (2 mg/kg bw)

Time point	Equivalent concentration (mg/kg)
10 min	0.663
20 min	1.391
40 min	1.878
1 h	2.017
1.5 h	1.963
2 h	1.911
4 h	1.532
8 h	0.995
24 h	0.357
32 h	0.358
48 h	0.230
72 h	0.162

Distribution and plasma kinetics

Flupyradifurone was quickly distributed as can be seen form the analysis of plasma at different time points. The maximum concentration of radioactivity (C_{max}) was already reached one hour after administration. At this time, the radioactivity level in plasma corresponded approximately to the equidistribution concentration. The plasma concentration then declined to approx. 50% of C_{max} within 8 hours and to approx. 10% of the maximum value within 48 hours. At the time of sacrifice, the plasma concentration amounted to ca. 8% of C_{max}.

The mean values of total radioactivity were used for a toxicokinetic modelling using the TOPFIT software. The fitting was conducted assuming a two-compartment model with no data weighting. A good fit was achieved for the entire time range (Figure 6.1.1.-03). The AUC was 45.4 mg/L*h and the half life of elimination was 49.9 hours.

Figure 6.1.1-03. Timecourse of radioactivity in the plasma following a single oral dose of [ethyl-1-^{14}C] flupyradifurone (2 mg/kg bw)

Excretion

Only a very small proportion of the dose (0.2% in total) was detected in the expired air. This result confirms the stability of the radio label in the ethyl group with regard to extensive metabolic transformation. The major route of excretion was renal. In total, approximately 82% of the dose was detected in urine, the majority of which (about 76% of the dose) was excreted within 24 hours. Faecal excretion accounted for ca. 13.5% of the given dose. Also the major part of faecal residues (about 11% of the dose) was excreted within 24 hours after treatment. These results are in good accordance with the excretion behavior detected in all other rat studies with flupyradifurone. The cumulative excretion results in percent of the administered radioactivity are summarized in Table 6.1.1.-34.

Table 6.1.1.-34. Cumulative excretion of radioactive residues via urine, faeces and expired air after a single oral dose of [ethyl-1-^{14}C] flupyradifurone (2 mg/kg bw).

	Time [h]	% of dose
Expired Air	24	0.15
	48	0.19
	72	0.20

	72	82.24
Total		**95.95**

Radioactive residues in organs and tissues at sacrifice

Approximately 4% of the dose was detected in the body at sacrifice 72 hours after oral administration; 0.73% was found in the GIT and 3.19% in the body without GIT. The residual concentration of radioactivity was in the range of 0.025 to 0.158 mg/kg. The lowest concentration was detected in the Harderian gland and the highest value was found in plasma. However, concentrations for most organs and tissues were very similar and in the range of approximately 0.05 to 0.1 mg/kg. The equivalent concentrations of the residual radioactivity in organs and tissues at sacrifice are presented in Table 6.1.1.-35.

Table 6.1.1.-35: Total radioactive residues in organs and tissues at sacrifice after a single oral dose of [ethyl-1-^{14}C] flupyradifurone (2 mg/kg bw)

Metabolites in urine and faeces

Flupyradifurone was metabolized into a number of metabolites. The unmetabolized parent compound represented the predominant part of the radioactivity in urine while in faeces the metabolite BYI 02960-OH was more prominent. BYI 02960-DFA was detected in both, urine and faeces. All other identified and characterized metabolites represented a minor part of the dose and were not common to either urine or faeces. A summary of the distribution of the parent compound and metabolites in urine and faeces is provided in Table 6.1.1.-36.

Table 6.1.1.-36. Amounts of metabolites in urine and faeces after a single oral dose of [ethyl-1-^{14}C] flupyradifurone (2 mg/kg bw)

Acceptability

The study was considered acceptable.

Conclusions

Flupyradifurone was almost completely absorbed; more than 85% of the administered dose was detected in the urine and the body without GIT at sacrifice The excretion of radioactivity was fast and mainly renal. The major part of the dose (>87%) was excreted within 24 hours after treatment, but continued until sacrifice. At sacrifice, a small proportion of ca. 3% of the dose was detected in the body without GIT. The residue concentration in plasma was 0.158 mg/kg; for most other organs and tissues levels were in the range between 0.05 and 0.1 mg/kg. The parent compound, one major and five minor metabolites were identified in all samples. Identification rates were >95% of the total radioactivity in urine and >85% of the total radioactivity in faeces..The metabolic transformation of flupyradifurone was principally oxidative in nature and took place at 3 different positions of molecule

Study design

The study was performed according to OECD Guideline 417. Male and female rats in groups of four rats were administered orally by gavage a single dose of flupyradifurone at target dose levels of 3 mg/kg bw (Table 6.1.1.-24). Flupyradifurone was radiolabelled with ^{14}C in the 1-position of the ethyl side chain:

* denotes the position of the ^{14}C-label

Groups of male and female rats (4/time point/sex) were orally administered with a single dose of 3 mg/kg bw [ethyl-1-^{14}C] flupyradifurone by gavage in 0.5% aqueous Tragacanth®. The animals were sacrificed at 1, 6 or 24 hours after dosing. The total radioactivity was determined over different time periods (0 - 1 hour, 0 - 6 hours, or 0 – 24 hours) in urine, while in plasma, liver, kidney, muscle and fat tissue after sacrifice. The metabolism was investigated in urine, plasma, and in extracts of liver, kidney, muscle, and fat tissue. Samples were analyzed by radio HPLC, radio TLC, LC-MS and NMR methods.

Results

Recovery

The detailed recovery rates of radioactivity in urine, organs and tissues and the combined GIT and faeces sample are shown in Table 6.1.1-38. The mean recoveries for male rats ranged from approximately 96% to 98% and for female rats from approximately 100% to 104% of the given dose. In male rats, sacrificed at 1 hour after administration, approx. 64.6% of the dose was detected in organs and tissues and approx. 27.2% in the GIT and faeces sample (Table 6.1.1.-38). After 24 hours, the value for organs and tissues declined to approx. 7.5%. These values indicated a fast distribution of the absorbed radioactivity within the body followed by a quick elimination finally leading to a significant increase of the urinary excretion from ca. 6.2% to ca. 71.8%. The situation was slightly different in female rats. After sacrifice at 1 hour h after administration, approx. 81% of the dose was detected in organs and tissues and approx. 13.9% in the GIT and faeces sample. After 24 hours, the value of organs and tissues declined to approx. 5.3%. These values indicated again a fast distribution of the absorbed radioactivity within the body followed by a quick elimination finally leading to a significant increase of the urinary excretion from approx. 8.8% to approx. 85.9%.

Metabolism

Table 6.1.1.-39 shows the amount of flupyradifurone and its metabolites after 1, 6, and 24 hours in urine of male and female rats as percentage of the given dose. In urine, the parent compound was the dominating radioactive component. The concentrations of radioactivity in plasma can be found in Table 6.1.1.-40, in liver in Table 6.1.1.-41, in kidney in Table 6.1.1.-42, in muscle in table 6.1.1.-43 and in fat tissue in table 6.1.1.-44. Flupyradifurone was intensively metabolized. Metabolic reactions took place at least at 3 different structural positions of the molecule. The majority of the radioctive residues were identified (approx. 97 - 100% in plasma, and in extracts of organs and tissues as well as ≥ 95% of radioactivity in urine). In the 24 hours samples of plasma, and organs and tissues BYI 02960-DFA was by far the dominating metabolite accounting for more than 50% of the radioactivity. All other

identified metabolites contributed to less than 10%. The contribution of the parent compound in these samples ranged from 6 to 38% of the radioactivity. In urine, the parent compound was the dominating radioactive component (approximately 48% of the dose in males and 77% in females).

The metabolism was qualitatively similar in male and female rats, but with quantitative differences. The degradation of the parent compound to the different metabolites in male rats was significantly higher than in female rats.

Table 6.1.1.-39. Quantification of parent compound and metabolites in urine of male and female rats sacrificed 1 h, 6 h, and 24 h after a single oral dose of [ethyl-1-^{14}C] flupyradifurone (3 mg/kg bw)

Acceptability

The study was considered acceptable.

Conclusions

The distribution of the radioactivity within the organs and tissues (*i.e.* blood, liver, kidney, muscle and fat tissue) showed a distinctive preference for liver and kidney as the main metabolizing and excretory organs. The highest radioactivity concentrations were measured in plasma, and in organs and tissues at one hour after administration. They decreased significantly within the test period of 24 hours. There were no indications of irreversible binding or retention of radioactivity in organs and tissues. The parent compound, major and several minor metabolites were identified in all samples. Identification rates were high with ≥ 95% of radioactivity in urine and approx. 93 - 100% of the radioactivity in plasma, organs and tissues. The metabolic transformation of flupyradifurone was principally oxidative in nature and took place at least at 3 different structural positions of the molecule.
BYI 02960-DFA was by far the dominating metabolite in plasma, organs and tissues. On the other hand, the parent compound was the main constituent in urine. With regard to the extent of metabolism, a clear sex difference was observed since it was higher in male than in female rats. The metabolic degradation of the parent compound was much less pronounced in females as compared to males.

B.6.1.2 Toxicokinetic studies – Repeated dose, oral route

All single dose experiments revealed no indication of a potential for retention, accumulation and/or persistence of the administered radioactivity in organs or tissues. This observation is supported by the low log P_{OW} of BYI 02960 of 1.2. Therefore, in line with paragraph 26 of the OECD Test Guideline 417 (July 22nd, 2010), a repeated dose study was not considered necessary.

Results from expert consultation 2.2.

The RMS considers that from a scientific point of view there is no need for a toxicokinetic study with repeated dosing.

It was noted that after single dose, residual radioactivity was measured in fatty tissues/fat.

Considering the radioactive labelling, it is expected that residues can also be related to metabolites.

The biphasic kinetic was not evident in the different studies available.

Considering all the information available, the experts agreed that there is no potential for bioaccumulation, flupyradifurone being completely absorbed and excreted according to a biphasic kinetic.

The waiving of the repeat dose toxicokinetic study was agreed by the experts.

B.6.1.3 List of identified metabolites

A comprehensive list of major metabolites detected in the rat is provided in the following table.

Report Name	Chemical Structure	IUPAC Name
active substance: BYI 02960		4-[[(6-chloropyridin-3-yl)methyl](2,2-difluoroethyl)amino]furan-2(5H)-one
BYI 02960-OH		4-{[(6-chloropyridin-3-yl)methyl](2,2-difluoroethyl)amino}-5-hydroxyfuran-2(5H)-one
BYI 02960-iso-OH		

BYI 02960-OH-gluA (isomer 1)		
BYI 02960-OH-gluA (isomer 3)		3-{[(6-chloropyridin-3-yl)methyl](2,2-difluoroethyl)amino}-5-oxo-2,5-dihydrofuran-2-yl beta-D-glucopyranosiduronic acid
BYI 02960-hippuric acid		N-[(6-chloropyridin-3-yl)carbonyl]glycine

B.6.1.4 Proposed metabolic pathway

B.6.1.5 Summary and conclusions

Summary

Absorption, distribution, excretion and metabolism of flupyradifurone was investigated using three different labelling positions. The active substance was labelled with ^{14}C in the pyridinylmethylene bridge, in the 4-position of the furanone ring and in the 1-position of the ethyl side chain:

Pyridinylmethyl-^{14}C flupyradifurone

Furanone-4-^{14}C flupyradifurone

Ethyl-1-^{14}C flupyradifurone

The pyridinylmethyl-labelled compound was used in an ADME-study in which male and female rats were orally administered with a single low dose of 2 mg/kg bw or a high dose of 200 mg/kg bw. Due to the high water solubility of flupyradifurone, male rats were also given an intravenous dose of 2 mg/kg bw. In this study, the excretion via urine and faeces was investigated as well as the distribution in the plasma and the radioactivity concentration in organs and tissues at sacrifice. The metabolism was investigated in urine and faeces.

A quantitative whole body autoradiography study was conducted also using the pyridinylmethyl-labelled compound following a single oral dose of 5 mg/kg bw to male and female rats. In this study the excretion of radioactivity was determined in urine, faeces and expired air, as well as the distribution in the plasma and the radioactivity concentration in the organs and tissues at various time points.

The furanone-4-labelled compound was used in an ADME-study in which male and female rats were orally administered with a single dose of 2 mg/kg bw. In this study, the excretion via urine and faeces was investigated as well as the distribution in the plasma and the radioactivity concentration in the organs and tissues at sacrifice. The metabolism was investigated in urine and faeces.

A quantitative whole body autoradiography study was also conducted using the furanone-4-labelled compound following a single oral dose of 5 mg/kg bw to male and female rats. In this study the excretion of radioactivity was determined in urine, faeces and the expired air as well as the distribution in the plasma and the radioactivity concentration in the organs and tissues at various time points.

In an organ metabolism study, male and female rats were orally administered with a single dose of 3 mg/kg bw [furanone-4-^{14}C] flupyradifurone. Animals were sacrificed 6 hours after dosage and the metabolism was investigated in urine, plasma, and in extracts of liver, kidney, muscle and fat tissues.

The ethyl-1-labelled compound was used in an ADME-study in which male rats were orally administered with 2 mg/kg bw. In this study, the excretion via urine, faeces and expired air was investigated as well as the distribution in the plasma and the radioactivity concentration in the organs and tissues at sacrifice. The metabolism was investigated in urine and faeces.

In an organ metabolism study, male and female rats were orally administered with a single dose of 3 mg/kg bw [ethyl-1-^{14}C] flupyradifurone. The animals were sacrificed at 1, 6 or 24 hours after dosing. The total radioactivity was determined over the different time periods in urine, while in plasma, liver, kidney, muscle and fat tissue at different time points after sacrifice. The metabolism was investigated in urine, plasma, and in extracts of liver, kidney, muscle, and fat tissue.

Conclusions

Following oral administration of a single low dose of flupyradifurone to male and female rats, the gastrointestinal absorption of radioactivity was high. It accounted for >80 % of the dose independent of the labelling position used. The value of >80% can be used for further toxicological risk assessment. Excretion was very fast, mainly renal and almost completed after 24 hours. No radioactivity was detected in the expired air after dosing of the pyridinylmethyl- and ethyl-1-labelled compounds, proving the stability of these labelling positions in the molecule. Only after administration of [furanone-4-^{14}C] flupyradifurone between 1% and 3% of the administered radioactivity was exhaled. This demonstrated that for a small portion of the dose (higher in male than in female rats) the furanone ring of the molecule obviously was opened and was subject of biotransformation to C-1 fragments.
The maximum plasma concentration was reached in most cases within 1 or 2 hours after administration of low doses. Only after administration of the high dose of 100 mg/kg bw the peak plasma concentration was observed between 2 and 4 hours after dosage. After reaching the peak concentration, the radioactivity levels in plasma declined steadily by several orders of magnitude in all studies independent of sex or labelling position of the test compound.

Quantitative whole body autoradiography revealed a fast absorption and distribution of the test compound with peak values observed already 1 hour after administration. At this time, the concentrations in liver and kidney were significantly higher than in blood, suggesting a preferred clearance from blood and distribution mainly to these organs which are mainly responsible for metabolism (liver) and excretion (kidney). Higher concentrations than in blood were also detected in the myocardium (heart) and in several glands. Very low levels were found in the brain, spinal cord and renal fat tissue. These results were similar in male and female rats, and independent of the labelling position of the test compound. A fast decline of radioactivity concentrations was observed for all organs and tissues in male and female rats during the entire test period. Concentrations fell for most organs and tissues below 5% of the maximum concentration after one day. After seven days, only very low concentrations were found in a few organs and tissues of rats dosed with the pyridinylmethyl-labelled test compound. In the study using the furanone-4-labelled compound, low radioactive residues were measured in almost all organs and tissues due to the incorporation of C1- or C2-fragments into the endogenous carbon pool. The residues in male rats were higher by a factor of 1.4 to 4.7 as compared to female rats. A similar ratio of approximately 3 (male/female) was also found for the formation of $^{14}CO_2$, and originates presumably from sex related differences in metabolism leading to more C1- and C2-fragments and also higher incorporation of these components into the

endogenous carbon pool in male rats. In general males and female rats exhibited very similar absorption, distribution and excretion behaviour. The results of these studies demonstrate that there is no indication of any accumulation or significant retention of radioactivity in male and female rats. This observation is supported by the low P_{OW} of 1.2. Concentrations of radioactivity detected in tissues and organs at sacrifice were either very low or below the limit of detection.

Flupyradifurone was intensively metabolised in the rat. Numerous metabolites were formed, most of them being minor ones. The parent compound represented the predominant part of the radioactivity in urine of male and female rats. In faeces of male rats, the metabolite BYI 02960-OH was more prominent than the parent compound. Two metabolites, BYI 02960-6-CNA and BYI 02960-hippuric acid were also prominent in male but not in females rats. The organ metabolism study using the ethyl-1-^{14}C label showed that in the 24 hours samples of plasma, and organs and tissues BYI 02960-DFA was by far the dominating metabolite accounting for more than 50% of the radioactivity. In general, the metabolic profiles in urine and faeces were very similar for both sexes but male rats showed a higher rate of metabolite formation as compared to female rats.

The principal metabolic reactions of flupyradifurone in rats were:

- Hydroxylation followed by conjugation with glucuronic acid or sulfate,
- cleavage of the difluoroethyl group forming BYI 02960-des-difluoroethyl, and difluoroacetic acid (BYI 02960-DFA),
- cleavage of the molecule at the pyridinylmethylene bridge forming BYI 02960-6-CNA, which was further conjugated with glycine to BYI 02960-hippuric acid and BYI 02960-difluoroethyl-amino-furanone.
- The figure below schematically shows the sites of the molecule, which are involved in the metabolic reactions:

Summarizing, the results of the metabolism studies conducted in the rat, a proposed metabolic pathway of flupyradifurone can be described as shown in this figure:

B.6.2 ACUTE TOXICITY INCLUDING IRRITANCY AND SKIN SENSITISATION (ANNEX IIA 5.2)

B.6.2.1 Acute toxicity

STUDY 1

Characteristics

reference	:	[redacted]	exposure	:	Once by gavage
type of study	:	Acute oral toxicity study	doses	:	300, 2000 mg/kg bw
year of execution	:	2009	vehicle	:	2% Cremophor EL in tap water
test substance	:	BYI 02960 (batch 2009-000239, purity 96.2%)	GLP statement	:	Yes
route	:	Oral	guideline	:	According to OECD 423
species	:	Rat, Wistar Hsd Cpb:Wu	acceptability	:	Acceptable
group size	:	3f (step 1 and step 2)/dose	**LD50-cut off**	:	>300-2000 mg/kg bw

Study design

The study was performed in accordance with OECD 423.

Four groups of three fasted female Wistar rats (HsdCpb: WU) were given a single oral dose (10 mg/lkg) of BYI 02960 (batch 2009-000239, purity 96.2%) in 2% Cremophor EL. Clinical signs and mortality rates were determined several times on the day of administration and subsequently normally once daily for an observation period of at least 14 days. Weight gain of the animals was checked weekly until the end of the study. Animals which died or were killed in moribund state were weight (except on day of administration) and dissected as soon as possible and examined macroscopically. Surviving animals were sacrificed, dissected and examined macroscopically.

Results

Mortality:

Dose mg/kg bw	Mortality	Time of death
1st 2000	1/3	2h
2nd 2000	3/3	3h
1st 300	0/3	--
2nd 300	0/3	--

Symptoms of toxicity:

In animals dosed with 2000 mg/kg bw clinical signs included decreased motility, tremor, piloerection, labored breathing and clonical cramps. In animals treated with 300 mg/kg bw breathing sounds were noted.

Body weight:

The mean body weights increased throughout the study period.

Pathology:

In animals dosed with 2000 mg/kg that died during the observation period gross pathological findings included black or black spotted liver and hemorrhagic lung. No particular findings were observed in the surviving animals.

Acceptability

This study is considered acceptable.

Conclusions

The LD50-cut off of BYI 02960 was found to be >300-2000 mg/kg bw.

STUDY 2

Characteristics

reference	:	[redacted]	exposure	:	24 hours on a 10% skin area (semi-occlusive)
type of study	:	Acute dermal toxicity study	doses	:	2000 mg/kg bw
year of execution	:	2009	vehicle	:	Distilled water
test substance	:	BYI 02960 (batch 2009-000239, purity 96.2%)	GLP statement	:	Yes
route	:	Percutaneous	guideline	:	According to OECD 402
species	:	Rat, Wistar Hsd Cpb:Wu	acceptability	:	Acceptable
group size	:	5/sex	**LD_{50}**	:	>2000 mg/kg bw

Study design

The study was performed in accordance with OECD 402.

Groups of five animals/sex were exposed to BYI 02960 (batch 2009-000239, purity 96.2%) The test material was moistened and applied to a skin area of 30 cm^2 at a dose of 2000 mg/kg bw under semi-occlusive dressing. After 24 hours the dressings were removed and the area was rinsed. Clinical sign and mortality rates were determined several times on the day of application and subsequently at least once daily for an observation period of at least 14 days. The weight gain of the animals was checked weekly until the end of the study. At the end of the study animals were sacrificed, dissected and examined for gross pathological changes.

Results

Mortality: No mortality was observed

Symptoms of toxicity: No treatment related findings were observed

Body weight: The mean body weights increased throughout the study period.

Pathology: No macroscopic pathologic abnormalities were observed.

Acceptability

The study is considered acceptable.

Conclusions

The acute dermal LD50 of BYI 02960 in male and female rats was found to be greater than 2000 mg/kg bw.

STUDY 3

Characteristics

reference	:	[redacted]	exposure	:	4 hours; nose-only
type of study	:	Acute inhalation toxicity study	doses	:	12.33 mg/L (nominal concentration), 4.7 mg/L (analytical concentration) MMAD 2.04 with GSD 1.86
year of execution	:	2009	vehicle	:	50% (w/w) PEG 400 (Lutrol)
test substance	:	BYI 02960 (batch 2009-000239, purity 96.2%)	GLP statement	:	Yes
route	:	Inhalation	guideline	:	According to OECD 403
species	:	Rat, Wistar Hsd Cpb: WU (SPF)	acceptability	:	Acceptable
group size	:	5/sex	**LC_{50}**	:	> 4.7 mg/L

Study design

The study was performed in accordance with OECD 403 (1981).

Five male and five female Wistar Hsd Cpb:WU (SPF) rats were simultaneously exposed under nose only conditions for 4 h. The test article was aerosolized as 50% (w/w) solution in PEG 400 (Lutrol). Clinical signs and mortality rates were examined several times on the day of exposure and at least once daily for an observation period of 14 days. At the end of the study animals were sacrificed, dissected and gross pathological changes were recorded.

Results

Mortality: No mortality occurred.

Symptoms of toxicity:

Clinical signs after exposure to 4.7 mg/L BYI 02960 included increased breathing, labored breathing patters, irregular breathing, piloerection, motility reduced or increased, anxiety, tremor, limp, gait high-legged, exophthalmia, nose red encrustations, stridor, and abdominal position with uncoordinated movements. 48 hours after exposure all rats were without clinical signs.

Body weight: No treatment related effect on body weight was observed.

Pathology: No macroscopic pathologic abnormalities were observed.

Acceptability

The study is considered acceptable.

Conclusions

Acute LD_{50} for male and female rats was found to be >4.7 mg/L.

B.6.2.2 Irritation and sensitisation

STUDY 1

Characteristics

reference	:	[redacted]	exposure	:	4-hours semi-occlusive
type of study	:	Skin irritation study	doses	:	0.5 g
year of execution	:	2009	vehicle	:	Distilled water
test substance	:	BYI 02960 (Batch 2009-000239, purity 96.2%)	GLP statement	:	Yes
route	:	Dermal	guideline	:	According to OECD 404
species	:	Rabbit, New Zealand White Crl:KBL(NZW)BR	acceptability	:	Acceptable
group size	:	3 females	**Effect**	:	Not skin irritating

Study design

The study was performed in accordance with OECD 404 (2002).

Three New Zealand female rabbits (Crl:KBL(NZW)BR) were exposed to 0.5 g of pulverized BYI 02960 (purity 96.2%) moistened with water on a skin area of 2.5 x 2.5 cm^2 under semi-occlusive dressing. After 4 hours of exposure the patch was removed and the exposed area was washed with water. Dermal irritation was scored at approximately 1, 24, 48 and 72 hours after patch removal.

Results

The results are summarised in the tables below.

Individual irritation scores

Scores observed after	**1 hour**	**24 hours**	**48 hours**	**72 hours**
Erythema	0/0/0	0/0/0	0/0/0	0/0/0
Oedema	0/0/0	0/0/0	0/0/0	0/0/0

Mean value irritation scores

Animal	mean 24-72 hrs	
	erythema	oedema
1	0	0
2	0	0
3	0	0
mean	0	0

Acceptability

The study is considered acceptable.

Conclusions

BYI 02960 was found to be non-irritating to rabbit skin.

STUDY 2

Characteristics

reference	:	[redacted]	exposure	:	single instillation in conjunctival sac
type of study	:	Acute eye irritation study	doses	:	0.1 g
year of execution	:	2009	vehicle	:	none
test substance	:	BYI 02960 (Batch 2009-000239, purity 96.2%)	GLP statement	:	Yes
route	:	Ocular	guideline	:	According to OECD 405
species	:	Rabbit, New Zealand White Crl:KBL(NZW)BR	acceptability	:	Acceptable
group size	:	Three females	**Effect**	:	Not eye irritating

Study design

The study was performed in accordance with OECD 405 (2002).

0.1 g of the pulverized substance was placed into the conjunctival sac of one eye of the first animal. The other eye, which remained untreated, served as control. The eye was rinsed approximately 24 hours following instillation. Eye irritations were scored at 1, 24, 48 and 72 hours post application.

Results

The results are summarised in the tables below.

Individual irritation scores

Scores observed after	**1 hour**	**24 hours**	**48 hours**	**72 hours**
Cornea/opacity	0/0/0	0/0/0	0/0/0	0/0/0
Iris	0/0/0	0/0/0	0/0/0	0/0/0
Conjunctiva redness	2/2/2	2/1/1	0/0/0	0/0/0
Conjunctiva chemosis	0/0/1	1/0/0	0/0/0	0/0/0

Mean value irritation scores

Animal	mean 24-72 hrs			
	Corneal opacity	Iris	Conjunctiva redness	Conjunctiva chemosis
1	0	0	0.7	0.3
2	0	0	0.3	0
3	0	0	0.3	0
mean	0	0	0.4	0.1

Acceptability

The study is considered acceptable.

Conclusions

BYI 02960 is considered not irritating to eyes.

STUDY 3

Characteristics

reference	:	[redacted]	exposure	:	Epicutaneous application dorsal part of both ears; 3 consecutive days
type of study	:	Murine Local Lymph Node Assay (LLNA)	doses	:	0, 2, 10, 50%
year of execution	:	2009	vehicle	:	Dimethylformamide
test substance	:	BYI 02960 (Batch 2009-000239, purity 96.2%)	GLP statement	:	Yes
route	:	Dermal	guideline	:	According to OECD 429 (2002)
species	:	Mouse; Hsd Win: NMRI	acceptability	:	Acceptable
group size	:	6 female/group	**Effect**	:	Not skin sensitising

Study design

The study was performed in accordance with OECD 429 (2002). Instead of ^{3}H-Thymidin or ^{125}I-iododeoxyuridine and 10^{-5}M fluorodeoxyuridine incorporation to measure cell proliferation, cell counts were used as described below.

Six female NMRI mice (Hsd Win:NMRI) per group received 25 µl BYI 02960 (batch 2009-000239, purity 96.2%) at 0%, 2%, 10% and 50% epicutaneously onto the dorsal part of both ears. The treatment was repeated three times. The animals were sacrificed one day after the last application. After sacrifice the weight of the lymph nodes was determined and after crushing the lymph nodes through a sieve into a 12-well plate, the cell counts per ml were determined. Before the first treatment and before sacrifice the thickness of both auricles was measured and on day 4 of the study the ear weight of sacrificed animals was measured.

A concurrent positive control was not included. In the study it is indicated that the last reliability test (November 2008) using Alpha Hexyl Cinnamic Aldehyde formulated in acetone/olive oil (4:1) at concentration of 3%, 10% and 30% showed the sensitizing potential of the test item. However, the data was not included in the study.

Results

No signs of systemic toxicity were noticed. No effect on body weight was observed.

Treatment	Cell count Stimulation Index	Lymph node weight Stimulation Index	Ear weight Stimulation Index	Ear thickness Stimulation Index
Vehicle	1.00	1.00	1.00	1.00
2%	1.21	1.01	1.00	1.00
10%	0.97	0.92	1.00	1.01
50%	0.87	0.93	0.97	1.00

Acceptability

The study is considered acceptable.

Conclusions

BYI 02960 has no sensitising potential in the LLNA test in concentrations up to and including 50%.

B.6.2.3 Summary

The results of the acute toxicity, irritation and sensitisation studies are presented in table 6.2.3.1, 6.2.3.2 and 6.2.3.3, respectively.

Table 6.2.3.1 Acute toxicity, LD_{50}/LC_{50} values

Test substance	LD_{50}/LC_{50}	Species	Route	Vehicle	Reference

Table 6.2.3.3 Sensitisation studies

Test substance	Effect/Classification	Species	Route	Vehicle	Reference
BYI 02960	Not skin sensitising (LLNA)	Mouse	Dermal	Dimethylformamide	[redacted]. 2009

Flupyradifurone (BYI 02960) needs to be classified as Acute oral toxic Cat. 4 H302 according to Regulation (EC) 1272/2008. Flupyradifurone does not need to be classified on the basis of its acute dermal, and inhalation toxicology in rats (Category 5/ Unclassified). Flupyradifurone is considered not irritating to skin and eyes (Category 5/ Unclassified). Flupyradifurone does not have sensitising properties in a LLNA (Category 5/ Unclassified).

Table 6.2.3.3 Classification

Type of study	Species	Results	Classification (proposed)
Oral route	Rat	Mortalities observed at 2000 mg/kg; none at 300 mg/kg	Category 4 H302 (LD_{50} cut off >300-2000 mg/kg)
Dermal route	Rat	LD_{50} > 2 000 mg/kg	Category 5 / Unclassified
Inhalation	Rat	LC_{50} at 4 hours > >4.7	Category 5 / Unclassified

		mg/L (nose only) ~~4671 mg/m³~~	
Primary skin irritation	Rabbit	Non irritating	Category 5 / Unclassified
Eye irritation	Rabbit	Slight redness of the conjunctivae, reversed within 48 hours	Category 5 / Unclassified
Skin sensitization	Mouse	Not sensitizing	Category 5 / Unclassified

B.6.3 SHORT-TERM TOXICITY (ANNEX IIA 5.3)

B.6.3.1 28-day oral studies

Study 1

Characteristics

Reference	:	[redacted]	exposure	:	28 days
type of study	:	Exploratory 28-day rat oral toxicity study	dose	:	0, 75, 200, 350 mg/kg bw/day
year of execution	:	2006	vehicle	:	Corn oil supplemented with 10% ethanol and 10% water
test substance	:	BYI 02960 (Batch NLL 7780-11-5, purity 98.3%)	GLP statement	:	No
Route	:	gavage	guideline	:	-
Species	:	Rat, Wistar RJ: WI (IOPS HAN)	acceptability	:	Acceptable as range-finding study
group size	:	5/sex/dose	**NOAEL**	:	75 mg/kg bw/day

Study design

Groups of five animals per sex were orally dosed BYI 02960 (batch NLL 7780-16-5, purity 98.3%) for at least 28 days at dose levels of 75, 200 and 350 mg/kg bw/day. Animals were observed daily for mortality and clinical signs. Body weight and food consumption were recorded once weekly. Selected haematology and clinical chemistry parameters were assayed at the end of the study. At the end of the study, all animals were necropsied, selected organs were weighed and a range of tissues were examined microscopically. A portion of the liver was homogenized for microsomal preparations to determine cytochrome P-450 isoenzyme profile.

*p≤0.05 **p≤0.01, NC = no significant change

Two females were found dead on Study Day 6 at 350 mg/kg bw/day and one female died at 200 mg/kg bw/day. The only clinical sign found was increased salivation in all animals at all dose levels. Mean body weight was slightly reduced in males by between 5% to 8% (not statistically significant) and in females by 4% on Study Day 8 (not statistically significant). Mean food consumption was reduced by maximally 17% in males and by 29% in females.

Clinical chemistry evaluations showed a decrease in total bilirubin in both sexes at the highest two dose levels. Glucose concentration was only significantly affected in males at 200 and 500 mg/kg bw/day. Triglyceride concentration and alaline phosphatase were significantly increased in high dose females. Both creatinine concentration and alanine aminotransferase were significantly increased in mid and high dose females. Creatine concentration was also significantly increased in males at the

mid dose only. The statistically significant difference observed in total biliribun at 75 mg/kg in males was due to only one animal with a total bilirubin concentration of 0.0 µmol/l, while the mean of the remaining animals was 0.85 µmol/l. Therefore, this effect was considered to not be treatment-related.

Mean absolute and relative liver weights were 14 to 23% higher in males and 45 to 49% higher in females, compared to controls at 500 mg/kg bw/day. Upon macroscopic examination, enlargement and prominent lobulation of the liver were observed in both sexes. The liver effects observed at 200 and 350 mg/kg/day were correlated with microscopic centrilobular hepatocellular hypertrophy. The one incidence of prominent lobulation at 75 mg/kg/day in males were without associated microscopic findings and were considered not to be adverse.

Hepatocellular enzymatic activity assays showed that EROD activity was not found to be clearly affected by treatment. As BROD activity was induced at 350 mg/kg/day in both sexes and at 200 mg/kg/day in males, with no clear induction of PROD activity, BYI 02960 appears to be an inducer of the Cytochrome P-450 3 A family.

Acceptability

The study was not performed under GLP, but it was performed in a GLP-certified laboratory. The study is acceptable as a dose range finding study.

Conclusions

Based on the clinical chemical finding, the increased organ weights and pathological findings the NOAEL is set at 75 mg/kg bw/day.

Study 2

Reference	:	[redacted]	exposure	:	28 days
type of study	:	Exploratory 28-day rat oral study	dose	:	0, 500, 5000 ppm M: 0, 33.6, 385 mg/kg bw/day)
year of execution	:	2007	vehicle	:	none

group size	:	5 males/dose	**NOAEL**	:	33.6 mg/kg bw/d

Study design

Groups of five males were treated with BYI 02960 (batch NLL 7780-27-1, purity 99.7%) via the diet for at least 28 days at concentrations of 500 ppm (actual analyzed dose level of 410 ppm, which equates to 33.6 mg/kg/day BYI 02960) and 5000 ppm (equivalent to 385 mgkg bw/day). All animals were observed for mortality and clinical signs daily, body weight and food consumption were measured weekly. A detailed physical examination was performed weekly throughout the study. Before necropsy a blood sample was collected from the retro-orbital venous plexus of each surviving animal for selected clinical chemistry determinations and hormone analysis. All animals were necropsied, selected organs weighed and a range of tissues were taken, fixed and examined microscopically. The remaining portions of the liver were homogenized for microsomal preparations in order to determine cytochrome P-450 isoenzyme profile.

Results

*p≤0.05 **p≤0.01 NC = no significant change

At 5000 ppm mean body weight was reduced with a maximum of 19% during the first three weeks of the study. Overall mean cumulative body weight was significantly reduced by 38% compared to controls. Mean food consumption was consistently reduced by maximally 39% with the effect being more pronounced between study day 1 and 8. Total bilirubin and glucose concentration were significantly decreased and urea and total cholesterol were significantly increased at 5000 ppm. Hormone analysis showed a non significant increase in TSH (+81%) and a slight decrease (-19%) in the plasma which was considered treatment related. At the high dose relative liver and thyroid weight were significantly increased. These were associated microscopic findings including slight and moderate centrilobular hepatocellular hypertrophy and minimal and slight follicular cell hypertrophy.

Acceptability

The study was not performed under GLP, but it was performed in a GLP-certified laboratory. The study is acceptable as a dose range finding study.

Conclusion

Based on the clinical chemical findings, the increased relative liver and thyroids weights and the associated pathological findings, the dose level of 500 ppm (33.6 mg/kg/day) is considered to be the NOAEL in this study.

Study 3

~~*Dose adjusted for stability of DYI 02960 in the diet~~

Study design

BYI 02960 was administered continuously via the diet to groups of C57BL/6J mice (five/sex) for at least 28 days at concentrations of 300, 600 and 1200 ppm (equating approximately to 50, 98 and 207 mg/kg bw/day in males and 59, 122, 240 mg/kg bw/day in females). No stability study was performed on the submitted feed. Taking into consideration the available stability data (study SA 07131), the actual concentration received by the treated animals is assumed to be between 80% and 90% of nominal concentrations. Animals were observed daily for mortality and clinical signs. Body weight and food consumption were recorded weekly. Selected clinical chemistry parameters were determined at the end of the study. All animals were subjected to necropsy, selected organs were weighed and a range of tissues were fixed and examined microscopically.

*p≤0.05 **p≤0.01

There were no mortalities or clinical signs during the course of the study in any treatment group. Mean body weight was slightly reduced by 6% in males at 1200 ppm at study day 8 only. At 1200 ppm mean body weight gain/day was -0.03 g (p≤0.05) compared with 0.14 g/day in the control group between Study Days 1 and 8. Overall cumulative mean body weight gain was reduced by 15% between Study Days 1 and 29. As the effect on body weight was slight and transient and in the absence of other findings, it was considered to be a non-adverse effect of treatment. In historical control data from 28-day mouse study performed in the same laboratory with animals from the same strain and the same age, it can be seen that the range for mean cumulative body weight gain in males is between 2.2 to

3.9 grams. The cumulative body weight gain of 2.8 g for males administered at 1200 ppm is therefore within this range.
When compared to the controls, a higher alanine aminotransferase (+43%, p <0.01) and alkaline phosphatase (+21%, p <0.05) activities were observed in females at 1200 ppm. However in view of the variation of the individual values and the lack of a clear dose response these changes were considered not to be treatment-related.
Lower epididymis weights were found in treated animals when compared to controls but this change was considered not to be relevant since it was not associated with relevant histological findings. Mean absolute and relative spleen weights were statistically significantly higher in males at 300 ppm when compared to controls, but this change was considered not to be relevant since it was not dose-related.

Acceptability
The study was not performed under GLP, but it was performed in a GLP-certified laboratory. The study is acceptable as a dose range finding study.

Conclusion
In conclusion, continuous dietary administration of BYI 02960 to the C57BL/6J mouse for at least 28 days resulted in a No Observed Adverse Effect Level (NOAEL) in males and a No Observed Effect Level (NOEL) in females at a nominal concentration of 1200 ppm. However given the instability of BYI 02960 in rodent diet the actual concentration is considered to be in the region of 960 to 1080 ppm (166 to 186 mg/kg body weight/day for the males and 192 to 216 mg/kg body weight/day for the females, respectively).

Note: The storage stability in the other studies presented in the DAR gave no indication of concern.

Expert consultation 2.5.

The RMS noted that the decreased epididymis weight was within background historical control data. Due to the low number of animals by dose group, the study has to be considered as supplementary.

Considering the reduction of body weight gain at the high dose (15%), this might be considered as a LOAEL. Additionally ALT was also increased at the high dose. Based on these effects the experts agreed on a NOAEL of 98 mg/kg bw per day.

The dose was adjusted for the stability of the diet, and therefore calculated to a NOAEL of 166 mg/kg bw/d. The stability of the diet was not discussed during the expert meeting. Since the study is a preliminary study, and not critical for risk assessment. The RMS can agree with a worst-case NOAEL of 98 mg/kg bw/d.

Data requirement 2.2

Applicant to provide the historical control data regarding epididymis weights for the 28-day study in mice.

Epididymis weights observed in the 28-day toxicity mouse study

In this 28-day mouse study, Flupyradifurone was administered continuously via the diet to groups of C57BL/6J mice (5/sex/group) for at least 28 days at concentrations of 300, 600 and 1200 ppm (equating approximately to 50, 98 and 207 mg/kg bw/day in males and 59, 122 and 240 mg/kg bw/day in females.

Lower epididymis weights were found in treated animals when compared to controls but this change was considered not to be relevant since it was not dose-related and not associated with relevant histological findings. Furthermore the epididymis weights were within historical control data as can be seen in the following table. These historical control data were taken from two 28-day mouse toxicity studies performed in the same laboratory using mice from the same supplier administered with the same diet, A04Cp1-10 from S.A.F.E (SA 00226 performed in 2001 and SA 08036 performed in 2008; more 28-day mouse studies were performed in the laboratory during this period but epididymis weights were not collected).

Species	:	Beagles	acceptability	:	Acceptable as range-finding study
group size	:	2/sex/dose	**NOAEL**	:	62 mg/kg bw/day

Study design

Groups of two males and two females received BYI 02960 mixed in their diet at concentrations of 500, 2000 or 4000 ppm (equating approximately to 16, 62, 118 mg/kg body weight/day in males and 18, 77, 131 mg/kg body weight/day in females) for at least 28 days. Mortality and clinical signs were checked at least once daily. Food consumption was recorded daily and body weight was measured weekly. Once during the acclimatization phase and at the end of the treatment, Ophthalmological examination, detailed physical examination, blood analysis (haematology, clinical chemistry) and urinalysis were performed. All animals were subjected to a detailed necropsy. Selected organs were weighed and a range of tissues were taken and processed for histopathological examination.

*p≤0.05 **p≤0.01, NC = no significant change

There was an overall body weight loss in one male and an absence of overall weight gain in one female at 4000 ppm. Lower food consumption was observed in both male and female animals compared to the controls.

Hematology assessment revealed an increased platelet counts in both females (+43 and +36%, relative to their own pre-study value) and in one of the two males (+30%, relative to its own pre-study value) at 4000 ppm. At 2000 ppm, an increase was noted in one of the two females (+28%, relative to its own pre-study value). In isolation, these treatment-related changes were not considered to be adverse.

Enlarged thyroid glands were noted in 2/2 females at 4000 ppm but this change was not considered to be treatment-related as there was no effect on thyroid weight and there were no microscopic findings for the thyroid. In the liver, centrilobular glycogen accumulation was decreased in incidence and/or severity at 4000 and 2000 ppm in males and at 4000 ppm in females. This finding was considered to be treatment-related, but not adverse.

Acceptability

The study was not performed under GLP, but it was performed in a GLP-certified laboratory. The study is acceptable as a dose range finding study.

Conclusion

Based on the body weight loss and reduced body weight gain a NOAEL of 2000 ppm is set (equating to 62 mg/kg/day in males and to 77 mg/kg/day in females).

B.6.3.2 28-day dermal studies

Characteristics

reference	:	[redacted]	exposure	:	28 days, 6 h/d, semi-occlusive (10% of the total body surface area)
type of study	:	28-day dermal toxicity study	dose	:	50, 150 or 500 mg/kg bw/d
year of execution	:	2012	vehicle	:	Deionized water
test substance	:	BYI 02960, lot/batch no. 2009-000239, purity 96.2 %, beige powder	GLP statement	:	yes
route	:	Dermal	guideline	:	Partly in accordance with OECD 410
species	:	Rat, Wistar Han CRL: WI (HAN)	acceptability	:	acceptable
group size	:	10 /sex/dose	NOAEL	:	500 mg/kg bw/d

Study design

The study was performed partly in accordance with OECD 410: the highest dose should have resulted in toxic effects, or the limit dose of 1000 m/kg bw/d should have been used as the highest dose level. According to the study report, the high dose of 500 mg/kg bw/d was selected after consideration of the amount of test material that can be reliably applied to the skin. See acceptability. Male and female rats, 10 rats/sex/group (one control and three test substance-dosed groups) were administered vehicle or BYI 02960 (50, 150, or 500 mg/kg/day) daily by dermal application for at least 28 consecutive days (minimum of 6 h/day) and euthanized one day following the last dose. An additional 6 rats were used to test compound wetting suitability. Two rats/group were treated with 200 mg BYI 02960 using 2 mL deionized water, 0.5% methylcellulose, or corn oil. After at least 2 h of exposure, water was found to be an appropriate wetting agent and was chosen to be used to dose in this study.

* P<=5%

At 500 mg/kg/day

No adverse effects attributable to exposure to the test substance were observed.

In the first and second week of daily dermal administration, females had statistical significantly lower food consumption (g/animal/day) as compared to controls. In addition, food efficiency (g/kg bw/day) was significantly lower in the first week. These findings were not considered to be biologically significant as changes were not consistently affected in a dose-related fashion, were not found in males, and did not impact clinical observations or body weights at any point.

The absolute and relative liver weights at 500 mg/kg/day males were non-statistically decreased by 6% and 9%, respectively, compared to control rats. There were no test substance-related clinical or gross or microscopic pathology changes to correlate this finding.

At 150 mg/kg/day

No adverse effects attributable to exposure to the test substance were observed.

At 50 mg/kg/day

No effects attributable to exposure to the test substance were observed.

Females administered with 50 mg/kg/day had significantly lower food consumption in the second week as compared to controls. This finding was not considered biologically significant as changes were not consistently affected in a dose-related fashion, were not found in males, and did not impact clinical observations or body weights at any point.

Acceptability

The study is considered acceptable despite the fact that not the limit dose of 1000 mg/kg bw/d is used. It is not fully explained in the report why 500 mg/kg bw/d is the amount of test material that can be reliably applied to the skin. However, the study did not indicate any route-specific effects and NOAEL in this dermal study is higher than the oral NOAEL, that is used for the derivation of the reference values.

Conclusions

Based on the lack of adverse findings observed in this study, the 28-day dermal exposure NOAEL in male and female rats dosed with BYI 02960 was 500 mg/kg bw/day.

B.6.3.3 28-day inhalation studies

Based on the results of the acute inhalation toxicity study and the physical properties of BYI 02960 (compound not volatile with an extrapolated vapour pressure of 9.1×10^{-7} Pa at 20 °C), no repeat inhalation study is triggered.

B.6.3.4 Semichronic oral studies

Study 1

Reference	:	[redacted]	exposure	:	Repeated diet, 90 days
type of study	:	90-day rat oral toxicity study	dose	:	0, 100, 500, 2500 ppm M: 0, 6.0, 30.2, 156 mg/kg bw/day F: 0, 7.6, 38.3, 186 mg/kg bw/day
year of execution	:	2008	vehicle	:	none
test substance	:	BYI 02960 (batch NLL 7780-44-6, purity 99.5%)	GLP statement	:	yes
Route	:	diet	guideline	:	OECD 408
Species	:	Rats, Wistar Rj:WI (IOPS HAN)	acceptability	:	Acceptable
group size	:	10/sex/dose	**NOAEL**	:	6 ~~30.2~~ mg/kg bw/day

Study design

Groups of 10 males and 10 females Wistar rats were fed diets containing BYI 02960 (batch NLL 7780-44-6, purity 99.5%) at concentrations of 100, 500, 2500 ppm (equating to approximately 6.0, 30.2, 156 mg/kg bw/day in males and 7.6, 38.3, 186 mg/kg bw/day in females) for at least 90 days. An additional 10 animals per sex were fed control or high dose test diet for at least 90 days and subsequently fed control diet and observed for reversibility or persistence of toxic effects after a post-treatment recovery period of at least 28 days. The stability of the test substance in the diet (concentrations of 20, 100 and 2500 ppm) was checked over a period of at least 92 or 81 days of frozen storage followed by 10 days at room temperature or for at least 102 or 91 days of storage at room temperature. Clinical signs were recorded daily, body weight was measured weekly. Food consumption was measured twice weekly during the first 6 weeks of treatment and weekly thereafter. All surviving animals from the main study

groups were subjected to a neurotoxicity assessment (exploratory locomotor activity, open field observations, sensory reactivity and grip strength) during weeks 12 to 13 of the study. Ophthalmological examinations were performed on all animals during the acclimatization phase and on all animals of the control and high dose groups during week 13. Blood samples were collected from the sublingual vein of the first five suitable animals of each group for further determination of the test substance and its metabolites. Urine samples were collected overnight on the week before scheduled necropsies from all animals. Before scheduled necropsies a blood sample was collected from the retro-orbital venous plexus of each animal for haematology and clinical chemistry determinations. All animals were necropsied, selected organs weighed and a range of tissues were taken, fixed and examined microscopically.

*p≤0.05 **p≤0.01

At 2500 ppm, a lower body weight was observed in both sexes throughout the study (6-10%). A reduced mean body weight gain/day was observed in high dose males and in mid and high dose females. At 500 ppm the overall mean body weight gain was 12% lower than the controls in females at the end of the treatment period. In the absence of any other changes in the parameters assessed, this finding was considered not to be adverse.

Ophthalmological examination revealed haemorrhage of the iris and a damaged eye in one male and one female, respectively, exposed to 2500 ppm. In view of the single occurrence, these findings were considered incidental.

Haematological evaluation revealed a higher mean platelet count in high dose females when compared to the control group (+15%). In addition, mean total bilirubin and glucose concentrations were slightly lower in both sexes and mean total cholesterol and triglycerides concentrations were slightly higher when compared to the controls. At the end of the recovery phase, as the mean concentration remained slightly lower. The other treatment-related changes were considered to be reversible as no relevant difference was noted after the recovery period.

At 2500 ppm, mean liver to body weight ratio was statistically significantly higher in both sexes when compared to controls. This change, even if partly due to lower terminal body weight, was associated with relevant histopathological findings and was considered to be treatment-related. Mean thyroid gland to body weight ratio was statistically significantly higher in males when compared to controls and was associated with minimal follicular cell hypertrophy. At the end of the recovery phase, no treatment-related findings were observed in the liver and the thyroid gland. All the treatment-related findings observed at the end of the treatment period were thus considered to be reversible.

Acceptability

The study is considered acceptable

Conclusion

Based on the clinical chemical findings, the increased relative liver and thyroid weights and the associated pathological findings the NOAEL in this study is set at 500 ppm (approximately 30.2 mg/kg bw/day for males and 38.3 mg/kg bw/day for females).

Expert consulatation 2.6

At 500 ppm the overall mean body weight gain was 12% lower than the controls in females at the end of the treatment period. The RMS noted that this was not accompanied by effects on body weight.

With regard to the thyroid weight, the RMS highlighted that the effect was not observed in other studies, and only observed in males. Considering the severity of the effect (20% for the relative weight, statistically significant, and 17% for the absolute weight), the experts agreed that it had to be considered as adverse.

Based on these findings, the agreed NOAEL is 100 ppm, corresponding to 6 mg/kg bw per day.

Study design

The study follows OECD guideline 408 except for that FOB and ophthalmology were not performed.

Mice (10/sex/dose) received BYI 02960 (batch NLL 7780-44-6, purity 99.5%) at dietary concentrations of 100, 500 and 2500 ppm (equating approximately to 16, 81, 407 mg/kg bw/day in males and 19, 98, 473 mg/kg bw/day in females) for at least 90 days. Clinical signs were recorded daily, body weights and food consumption were measured weekly. On the day of necropsy, a blood sample was collected from the retro-orbital venous plexus of each surviving animal for selected clinical chemistry determinations. All animals were necropsied, selected organs weighed and a range of tissues were taken, fixed and examined microscopically.

*p≤0.05, **p≤0.01

There were no treatment-related mortalities during the study. One female of the mid dose group was killed for humane reasons on study day 61. Macroscopic examination revealed dilated and tear is esophagus, food content in thoracic cavity, enlarged adrenal glands, dark liver, white foci on stomach, atrophic/small thymus and enlarged bronchial lymph node. The cause of death was due to initial esophageal impaction followed by tearing and a subsequent local inflammation reaction and can therefore be considered incidental.

At 2500 ppm body weight was reduced in both sexes compared to control (max 11%). Mean body weight gain was reduced from study days 1 to 22 in males and between study days 1 and 8 in females. The overall cumulative mean body weight was reduced by 43% in males and 7% in females.

In the high dose animals clinical chemistry evaluation revealed a lower mean total cholesterol and total protein concentration in both sexes, and a higher urea and alkaline concentration in both sexes. Alanine aminotransferase activity was induced in females whereas albumin concentrations were reduced.

Mean absolute and relative liver weights were statistically significantly higher in females. Mean absolute kidney weight were statistically significantly lower in males when compared to controls. At macroscopic examination pale liver was noted in 6/10 females. At microscopic examination, a slight increase in severity of diffuse hepatocellular vacuolation was noted in the liver in both sexes. In the kidney, a loss of the normal multifocal/diffuse cortical epithelial vacuolation was noted in males. Relative brain and thymus weight were significantly increased in high dose males, without corroborating pathological finding these effects are likely due to the decreased body weight and are considered not treatment related.

Acceptability

The study is considered acceptable

Conclusion

Based on the clinical chemical findings, the increased liver and decreased kidney weights and the associated pathological findings the NOAEL in this study is set at 500 ppm (equating to 80.6 mg/kg bw/day in males and 98.1 mg/kg bw/day in females).

Study 3

**The highest dose (3600 ppm) was reduced to 2400 ppm from study week 9 onward due to clinical signs seen in two dogs on day 44 and continual weight loss in the high-dose group.*

Study design

The study was carried out according to OECD guideline 409.

BYI 02960 was administered via the diet to groups of 4 male and 4 female Beagle dogs at dose levels of 400, 1200 or 3600/2400 ppm for at least 90 days (12, 33 and 102/85 mg/kg bw/ day for males and 12, 41 and 107/78 mg/kg bw/day for females). The 3600 ppm dose group was reduced to 2400 ppm beginning study week 9 due to clinical signs seen in two of the dogs on Day 44 and continual weight loss in the high-dose group. Cage side observations and food consumption were recorded daily and detailed clinical observations and body weights were recorded weekly. Haematology, clinical chemistry, and urinalysis evaluations were performed on all animals once prior to administration of the test substance and from all animals during study weeks 5, 9, and 13. Ophthalmic examinations were performed pre-exposure and pre-sacrifice. A gross necropsy was performed, organ weights were taken, and micropathology was performed.

*p≤0.05, # Value not statistically significant due to a large SD from dogs that had normal values.

Clinical signs consisted of unsteady and stiff back legs and lower back in one high dose male and one high dose female. Body weight and body weight gain were reduced at 1200 and 3600/2400 ppm.

There was a compound-related reduction in RBC, Hgb, and Hct during the 1, 2, and 3 month hematology evaluations in both sexes at the high dose. In the 1200 and 3600/2400 ppm dose groups, there was a compound-related increase in creatine phosphokinase, aspartate aminotransferase and alanine aminotransferase at the 2-month test interval. The values for CK, AST, and ALT were normal at the 3 month evaluation.

Relative and absolute liver weights were increased in the high dose groups. There was a statistical siginificant compound-related increase in relative kidney weight for males in the mid and high dose group. The statistical increase in the prostate weight for the 3600/2400 ppm dose group males is not considered compound-related as these were young dogs and variations in prostate weight due to maturation can be expected. The statistical significant values for relative lung weight in the 400 and 1200 ppm male groups are not considered to be compound-related as there is no clear dose-response relationship.
Microscopic pathology revealed minimal brown pigments in Kupffers in the liver of high dose females an myofiber atrophy/degeneration in skeletal muscle in both sexes at the mid and high dose.

Historical control data from studies performed in 2010 and 2011:

Sex	Mean ±SD	range
Liver absolute weight (g)		
Males	259.6 ± 37.4	213.2 to 337.1
Females	233.3±45.7	185.4 to 336.5
Liver relative weight		
Males	2.93 ± 0.39	2.47 to 3..78
Females	3.07 ± .0.48	2.34 to 3.99
Prostate absolute weight:		
Males	7.02 ± 3.10	2.30 to 13.31
Prostate relative weight:		
Males	0.08 ± 0.039	0.26 ot 0.171
Females		
Lung absolute weight:		
Males	85.5 ± 7.2	74.6 to 96.2
Females	75.7 ± 12.5	66.9 to 109.6
Lung relative weight:		
Males	0.97 ± 0.09	0.81 to 1.12
Females	1.01 ± 0.25	0.84 to 1.71

Acceptability

The study is considered acceptable.

Conclusion

Based on reduced body weight, reduced body weight gain, clinical chemistry, significant increase in kidney weight and focal myofiber atrophy/degeneration the No Observed Adverse Effect Level is 400 ppm (12 mg/kg bw/day for males and females).

B.6.3.5 1-year toxicity study

Study 1

group size	:	4/sex/dose	**NOAEL**	:	7.8 mg/kg bw/day

Study design

The study was carried out according to OECD guideline 452.

Male and female Beagle dog (4/sex/dose) were fed diet containing BYI 02960 (batch 2009-000239, purity 96.2%) for at least one year at dietary level of 150, 300 and 1000 ppm, equivalent to 4.6, 7.8 and 28.1 mg/kg bwd/day for males and 4.1, 7.8 and 28.2 mg/kg bw/day for females). Body weights were measured weekly and food consumption was measured daily. All animals were generally observed at least daily for clinical signs of toxicity. Detailed clinical observations were preformed on a weekly basis. Ophthalmic exams were conducted prior to initiation of dosing and prior to termination of the study. Clinical chemistry, haematology and urinalysis evaluation were performed once prior to administration and at approximately 3, 6, 9 and 12 months. At the end of the study, a gross necropsy was conducted, organs were weighed and tissues were collected for microscopic examination.

*p≤0.05, **p≤0.01, () = Average severity of dogs with lesion: 1 (minimal) to 5 (severe).

Body weight or overall body weight gain were not affected by treatment. Body weight gain was reduced at 1000 ppm in females in the first week only (-88%). Food consumption, ophthalmology, urinalysis, haematology, clinical chemistry, organ weights and macroscopic pathology evaluations revealed no treatment-related effects. Test substance-related micropathological changes was limited to degeneration noted in skeletal muscle, protocol (gastrocnemius); and muscle, other (biceps femoris). Degeneration of the myofiber comprised of one or more of the following changes: atrophy, necrosis, and/or presence of inflammatory cells around the affected myofiber.

Acceptability

The study is considered acceptable

Conclusion

Based on micropathology findings in males and females, the LOAEL in this study was 1000 ppm, equivalent to 28.1 and 28.2 mg/kg bw/day for male and female dogs, respectively. The NOAEL in this study was 300 ppm, equivalent to 7.8 mg/kg bw/day for both male and female dogs.

B.6.3.6 Summary

The results of the subacute and semichronic toxicity studies are summarised in Tables 6.3.5.1 and 6.3.5.2, respectively.

Oral

Four subacute oral range-finding studies were performed, with rat, mouse and dog.

In a 28-day study with rats exposed to 0, 75, 200 or 350 mg/kg bw/d via gavage, toxicologically relevant effects were clinical chemical findings, increased organ weights and pathological findings in the 200 mg/kg bw/d group. The NOAEL in this study is set at 75 mg/kg bw/d.

In a 28-day study with rats exposed to 0, 33.6 or 385 mg/kg bw/d via diet, toxicologically relevant effects were clinical chemical findings, increased liver and thyroid weights and associated pathological findings in the 385 mg/kg bw/d group. The NOAEL in this study is set at 33.6 mg/kg bw/d.

In a 28-day study with mouse exposed to 300, 600 and 1200 ppm (equating approximately to 50, 98 and 207 mg/kg bw/day in males and 59, 122, 240 mg/kg bw/day in females) via diet, no toxicologically relevant effects were observed. The NOAEL in this study is set at 98 mg/kg bw/d.

In a 28-day study with dogs exposed to 0, 500, 2000 or 4000 ppm (equating approximately to 0, 16, 62, 118 mg/kg body weight/day in males and 0, 18, 77, 131 mg/kg body weight/day in females) via diet, toxicologically relevant effects were body weight loss and reduced body weight gain at the 4000 ppm group. The NOAEL in this study is set at 2000 ppm (62 mg/kg bw/d).

Four semichronic oral studies were performed, with rat, mouse and dog.

In a 90-day toxicity study with rat exposed to 0, 100, 500, 2500 ppm (equating to approximately 0, 6.0, 30.2, 156 mg/kg bw/day in males and 0, 7.6, 38.3, 186 mg/kg bw/day in females) via diet, toxicologically relevant effects were clinical chemical findings, increased relative liver and thyroid weight and associated pathological findings in the 2500 ppm group, and thyroid weight effects in the 500 ppm males. The NOAEL in this study is 100 ~~500~~ ppm (6.0 ~~30.2~~ mg/kg bw/d).

In a 90-day toxicity study with mouse exposed to 0, 100, 500, 2500 ppm (equating approximately to 16, 81, 407 mg/kg bw/day in males and 19, 98, 473 mg/kg bw/day in females) via diet, toxicologically relevant effects were clinical chemical findings, increased relative liver and decreased kidney weights and associated pathological findings in the 2500 ppm group. The NOAEL in this study is 500 ppm (81~~80.6~~ mg/kg bw/d).

In a 90-day toxicity study with dog exposed to 0, 400, 1200 or 3600/2400 ppm (equating approximately to 0, 12, 33 and 102/85 mg/kg bw/ day for males and 0, 12, 41 and 107/78 mg/kg bw/day for females) via diet, toxicologically relevant effects were reduced body weight, reduced body weight gain, clinical chemistry, significant increase in kidney weight and focal myofiber atrophy/degeneration in the 1200 ppm group. The NOAEL in this study is 400 ppm (12 mg/kg bw/d).

In a 1-year toxicity study with dog exposed to 0, 150, 300 and 1000 ppm (equating approximately to 0, 4.6, 7.8 and 28.1 mg/kg bwd/day for males and 0, 4.1, 7.8 and 28.2 mg/kg bw/day for females) via diet, toxicologically relevant effects were micropathology (degeneration of the skeletal muscle (*gastrocnemius* and *biceps femoris* (atrophy, necrosis and/or presence of inflammatory cells)) findings in the 1000 ppm group. The NOAEL in this study is 300 ppm (7.8 mg/kg bw/d).

Dermal

Male and female rats, 10 rats/sex/group (one control and three test substance-dosed groups) were administered BYI 02960 (50, 150, or 500 mg/kg/day) daily by dermal application for at least 28 consecutive days (minimum of 6 h/day) and euthanized one day following the last dose. Based on the lack of adverse findings observed in the study, the 28-day dermal exposure NOAEL in male and female rats dosed with BYI 02960 was 500 mg/kg bw/day.

B.6.4 GENOTOXICITY (ANNEX IIA 5.4)

B.6.4.1 *In vitro*

Study 1

BYI 02960 did not cause any significant increase in the number of revertant colonies in either the presence or absence of metabolic activation. Therefore, BYI 02960 was non-mutagenic with or without S9 mix in the plate incorporation as well as in the pre-incubation modification of the Ames test.

Acceptability

The study is considered acceptable.

Conclusions

BYI 02960 is not mutagenic in the Ames test.

Study 2

Study design and results

Type of study: Ames test, plate incorporation and preincubation method

Indicator cells	Endpoint	Res. - act.	Res. +act.	Activation		Dose range	Reference
				Tissue	Inducer

Test substance: BYI 02960 (batch number PFV107N005; batch; purity 97.2%); tested in DMSO
Precipitation: No precipitation of the test substance was reported.
Toxicity: No toxic effects, evident as a reduction in the number of revertants (below the indication factor of 0.5), occurred in the test groups with and without metabolic activation. Only in experiment I in strain TA 1537 a minor reduction in the number of revertants (below the indication factor of 0.5), was observed with and without S9 mix at 5000 pg/plate.
GLP statement: yes
According to OECD 471: yes
Adequate positive (+S9: 2-AA; -S9: NaN_3, 4-NOPD, MMS) and negative (sterility and vehicle) controls were included.

BYI 02960 did not cause any significant increase in the number of revertant colonies in either the presence or absence of metabolic activation. Therefore, BYI 02960 was non-mutagenic with or without S9 mix in the Ames test.

Acceptability

The study is considered acceptable.

Conclusions

BYI 02960 is not mutagenic in the Ames test.

Study 3

Study design and results

Type of study: mammalian cells *in vitro*, cytogenetic assay

Indicator cells	Endpoint	Res. -act.	Res. +act.	Activation		Dose range[a]	Reference
				Tissue	Inducer		
Chinese hamster V79 cells	Chromosome aberration	-	-	rat liver	Aroclor 1254	-S9: 0, 500, 1000, 2000, 2500 and 3000 µg/mL (4 hours treatment, harvest 18 hours after the beginning of treatment) 0, 2000, 2500 and 3000 µg/mL (4 hours treatment, harvest 30 hours after the beginning of treatment) 0, 100, 200, 400, 600 and 800 µg/mL (18 hours treatment, harvest at the same time) +S9: 0, 500, 1000, 2000, 2500 and 3000 µg/mL (4 hours treatment, harvest 18 hours after the beginning of treatment) 0, 2000, 2500 and 3000 µg/mL (4 hours treatment, harvest 30 hours after the beginning of treatment)	Thum, M. (2009)

[a] Based on the results of the survival index and of the mitotic index, the following concentrations were selected for reading:
-S9:
500, 1000 and 2500 µg/mL (4 hours treatment, harvest 18 hours after the beginning of treatment);
2500 µg/mL (4 hours treatment, harvest 30 hours after the beginning of treatment);
200, 400 and 800 µg/mL (18 hours treatment, harvest at the same time).

+S9:
500, 1000 and 3000 µg/mL (4 hours treatment, harvest 18 hours after the beginning of treatment)
3000 µg/mL (4 hours treatment, harvest 30 hours after the beginning of treatment)

Test substance: BYI 02960 (batch number 2009-000239; purity 96.2%); tested in DMSO
Precipitation: No precipitation of the test substance was observed.
Toxicity: Without S9 mix cytotoxic effects were observed at 1000 µg/mL and above after 4 hours treatment and at 400 µg/mL and above after 18 hours treatment. With S9 mix cytotoxic effects were observed at 2000 µg/mL and above.
GLP statement: yes
According to OECD 473: yes
Adequate positive and negative controls were included.

Table 6.4.1-5 Summary of results (metaphases with aberrations, polyploidy metaphases, survival and mitotic index, 4 hours treatment)

Mitomycin C (0.03 µg/mL)	18	52.0	51.5***	4.5	71.0*	103	113.2

[a] The number of polyploid metaphases observed in a culture in addition to 100 metaphases analysed for chromosome aberrations were recorded (2 cultures);
[b] The mitotic index was determined by counting a total of 1000 cells per culture (2 cultures);

* relevant reduction of survival index;
** $p < 0.05$;
*** $p < 0.01$.

None of the cultures treated with BYI 02960 in the absence or presence of S9 mix showed statistically significant or biologically relevant increases of numbers of metaphases with aberrations. Based on the results of this test, BYI 02960 is considered not to be clastogenic for mammalian cells in vitro.

Acceptability

The study is considered acceptable.

Conclusions

BYI 02960 did not induce structural chromosome aberrations in V79 cells when tested up to and including cytotoxic concentrations.

Study 4

Study design and results

Type of study: mammalian cells *in vitro*, gene mutation test

Indicator cells	Endpoint	Res. –act.	Res. +act.	Activation		Dose range	Reference

[c] Due to contamination in one cell culture, for only one culture the mutant frequency was determined.
[P] precipitation of the test substance
* significant (α = 0.05) increase in the one-sided Dunnett Test.

BYI 02960 was tested up to 2944 µg/mL, a concentration which exceeded the requested limit concentration of 10 mM. Under both activation conditions, no cytotoxic effects were induced. There were no indications of mutagenic effects of BYI 02960 in the V79/HPRT forward mutation assay either without or with S9 mix.

Acceptability

The study is considered acceptable.

Conclusions

In this study, BYI 02960 has no mutagenic potency in vitro in the CHO/HPRT assay.

~~The test substance did not induce unscheduled DNA synthesis in mammalian cells.~~

B.6.4.2 *In vivo*

Study 1

Study design and results

Type of study: mouse micronucleus test

Indicator cells	Endpoint	Result	Dose range	Reference
Mouse, Crl:NMRI Two intraperitoneal injections separated by 24 hours: 5/male/dose (vehicle and positive control, low, mid and high dose)	Micronuclei (bone marrow)	-	Pretest dose selection: 10, 40, 100 and 1000 mg/kg bw (m/f) Main test: 10, 20 and 40 mg/kg bw Dosing route: intraperitoneal Dosing volume: 10 mL/kg bw Vehicle (corn oil) and an adequate positive control was included	[redacted] (2009)
Test substance: BYI 02960 (batch number: 2009-000239; purity 96.2%); tested in corn oil Toxicity: at all tested dose levels, apathy, roughened fur, loss of weight, sternal recumbency, spasm, periodically stretching of body and difficulty in breathing GLP statement: yes According to OECD 474: yes				

Table 6.4.2-1 Results of the micronucleus test with BYI 02960

Treatment group	Number of evaluated PCE	Number of NCE per 2000 PCE	MNNCE per 2000 NCE	MNPCE per 2000 PCE
Negative control (corn oil)	10,000	3800	1.5	3.4
BYI 02960				
10 mg/kg bw	10,000	3134	1.0	1.4
20 mg/kg bw	10,000	3139	1.9	3.0
40 mg/kg bw	10,000	3008	1.0	3.8
Positive control				
Cyclophosphamide (20 mg/kg bw)	10,000	3308	1.9	20.6*

* P < 0.01 in non-parametric Wilcoxon ranking test

There was no indication of a clastogenic effect of intraperitoneally administered BYI 02960 in the micronucleus test on the male mouse, i.e. in a somatic test system in vivo.

Acceptability

The study is considered acceptable.

Conclusions

BYI 02960 has no potential to induce micronuclei in mouse bone marrow cells.

Study 2

Study design and results

Type of study: mouse micronucleus test

Indicator cells	Endpoint	Result	Dose range	Reference
Mouse, Crl:NMRI Two intraperitoneal injections separated by 24 hours: 7/female/dose (vehicle and positive control, low, mid and high dose)	Micronuclei (bone marrow)	-	Pretest dose selection: 10, 50, 75 and 100 mg/kg bw (f) Main test: 12.5, 25 and 50 mg/kg bw Dosing route: intraperitoneal Dosing volume: 10 mL/kg bw Vehicle (10% DMSO / 90% corn oil) and an adequate positive control was included	[redacted] (2011)
Test substance: BYI 02960 (batch number: PVF107N005; purity 97.2%); tested in 10% DMSO / 90% corn oil Toxicity: at 25 mg/kg bw, reduction of spontaneous activity, eyelid closure and ruffled fur were observed; at 50 mg/kg bw reduction of spontaneous activity, eyelid closure, ruffled fur and abdominal position were observed GLP statement: yes According to OECD 474: yes				

Table 6.4.2-2 Results of the micronucleus test with BYI 02960

Treatment group	Number of evaluated PCE	PCE per 2000 erythrocytes	PCEs with micronuclei (%)
Negative control (corn oil)	14,000	1229	0.121
BYI 02960			
12.5 mg/kg bw	14,000	1250	0.114
25 mg/kg bw	14,000	1234	0.143
50 mg/kg bw	14,000	1177	0.093
Positive control			
Cyclophosphamide (40 mg/kg bw)	14,000	1125	2.264*

* P < 0.05 in non-parametric Mann-Whitney test

There was no indication of a clastogenic effect of intraperitoneally administered BYI 02960 in the micronucleus test on the female mouse.

Acceptability

The study is considered acceptable.

Conclusions

BYI 02960 has no potential to induce micronuclei in mouse bone marrow cells.

B.6.4.3 Summary

The results from the *in vitro* and *in vivo* genotoxicity studies are summarized in table 6.4.3-1 and 6.4.3-2, respectively.

Table 6.4.3-1 *In vitro* genotoxicity studies

Test substance	Type of study		Result		Reference
	Indicator cells	Endpoint	without activation	with activation	
BYI 02960	S. typh. TA 98 TA 100 TA 102 TA 1535 TA 1537	Point mutation	-	-	Herbold, B. (2009)
BYI 02960	S. typh. TA 98 TA 100 TA 102 TA 1535	Point mutation	-	-	Sokolowski, A. (2011)

Test substance	Type of study		Result		Reference
	Indicator cells	Endpoint	without activation	with activation	
	TA 1537				
BYI 02960	Chinese hamster V79 cells	Chromosome aberration	-	-	Thum, M. (2009)
BYI 02960	Chinese hamster V79 cells	Gene mutations (HGPRT)	-	-	Entian, G. (2009)

Table 6.4.3-2 In vivo genotoxicity studies

Test substance	Type of study		Result	Reference
	Species	Endpoint		
BYI 02960	Mouse, Crl:NMRI	Micronuclei (bone marrow)	-	[redacted] (2009)
BYI 02960	Mouse, Crl:NMRI	Micronuclei (bone marrow)	-	[redacted] (2011)

BYI 02960 was not mutagenic in two Ames tests.
BYI 02960 did not induce structural chromosome aberrations in V79 cells when tested up to and including cytotoxic concentrations and showed no mutagenic potency in vitro in the CHO/HPRT assay.
BYI 02960 did not induce micronuclei in mouse bone marrow cells in two separate in vivo studies.
Overall it can be concluded that BYI 02960 has no mutagenic or clastogenic potential.

B.6.5 LONG-TERM TOXICITY AND CARCINOGENICITY (ANNEX IIA 5.5)

B.6.5.1 Chronic toxicity and carcinogenicity

STUDY 1

Data requirement:
Applicant to provide the tabled results of body weight/body weight gain and haematological findings of the 2-year rat study and relevant historical control data.

Body weight and body weight gain changes
The body weight and body weight gains have been reported as follows in the study report.
At 2000 ppm in males, the mean cumulative body weight gain was significantly lower than controls during the first week of treatment (- 27%, p≤0.01) and over the first three months of the study (-13%, p≤0.01). Thereafter, mean cumulative body weight gain was comparable to controls. The mean body weight was lower compared to controls from Week 1 to Week 54 (statistically significant in most occasions). Thereafter the mean body weight was comparable to controls. In females, mean body weight and cumulative body weight gains

were lower compared to controls throughout the study (-5% to -17%; p≤0.01 or 0.001 for body weight and -18% to -62%; p≤0.001, 0.01 or 0.05 for cumulative body weight gains. Overall, the mean cumulative body weight gain was decreased by 23% when compared to controls at the end of the study, the mean body weight was 13% lower.

At 400 ppm, mean cumulative body weight gain was statistically significantly lower than in controls during the first week of treatment for males (-6%, p≤0.05) and females (-12%, p≤0.05) and was comparable to control thereafter. Mean body weight was not affected throughout the study.

At 80 ppm, there was no treatment-related effect on body weight parameters in either sex.

** Statistically different (p□0.01) from the control
* Statistically different (p□0.05) from the control
*** Statistically different (p□0.001) from the control

These data can be summarized as follows in the Table 2.

Table 2 : Body weight and body weight gain additional data

Dose (ppm)	0		80		400		2000		dr
	m	f	m	f	m	f	m	f	
BW W106	653	421	623 (-5%)	437 (+4%)	655	444 (+5%)	616 (-6%)	364 ds (-13%)	
BWG W1-106	416	256	392 (-6%)	271 (+6%)	420 (+1%)	275 (+7%)	379 (-9%)	198 ds (-23%)	

The historical control body weight data have been collected from carcinogenicity studies performed at Bayer CropScience (Centre of Toxicology, Sophia-Antipolis, France), initiated between February 2005 and January 2010. Only the studies in which the age of animals was identical at the start of the study were considered. This represents a group of 5 studies. For technical reasons, some body weight sessions were not recorded on the exact same day for all studies, therefore when possible the most approaching data were taken instead (details were provided and evaluated by the RMS).

Table 3: Historical body weight control data from carcinogenicity studies performed on Wistar rats initiated from February 2005 to January 2010

Haematological findings

The haemaological changes were reported as follows in the report M-428257-01-1:

Effects were observed at 2000 ppm only.
At 2000 ppm in males, relative to the controls, mean leucocyte counts were higher at Month 12 (+22%, p≤0.01), 18 (+31%, p≤0.01) and 24 (+63%, p≤0.05). This variation was associated with higher mean absolute lymphocyte count at Month 12 (+19%, p≤0.01) and 18 (+32%, p≤0.01) and with higher mean absolute neutrophil count at Month 12 (+36%, p≤0.05) and 24 (+143%, p≤0.05).
At 2000 ppm in females, throughout the first year of treatment, statistically significant differences were noted in some erythrocyte parameters. Mean hemoglobin concentration and/or mean corpuscular volume were lower; as a consequence mean hematocrit and/or mean corpuscular hemoglobin were lower too. These variations were very slight (≤ -4%, relative to the controls).
In this group, mean platelet counts were slightly higher (< +20%, relative to the controls) during the first year and mean total leucocyte count and mean absolute lymphocyte count were slightly higher at Month 4 (+31% and +34% respectively, relative to the controls) and at Month 6 (+34% and +42% respectively, relative to the controls).
Altogether these changes were considered not to be toxicologically relevant in view of their low magnitude and their transient occurrence.
The few other differences observed, even if statistically significant, were considered to be incidental and not treatment-related.

Haematological findings in males are tabulated in the table 5

Table 5: Haematological changes in the males during the rat carcinogenicity study with flupyradifurone

** : Significant ($p \leq 0.01$)

Statistical significances in the control findings are considered an error.

No effects of the treatment on the mortality were observed. Clinical signs were limited soiled fur, hyper-reactivity to external stimuli and resistance to handling, observed during the first year of treatment, and soiled fur and hair loss observed during the second year of treatment in high-dose males.

In high-dose females the mean body weight and cumulative body weight gain were lower compared to controls throughout the study (statistically significant). Overall the mean cumulative body weight gain was decreased by 23% when compared to the controls at the end of the study, the mean body weight was 13% lower. In high-dose males, mean body weight was lower compared to controls from week 1 to week 54 (statistically significant on most occasions); thereafter the mean body weight was comparable to the controls.

In high-dose females, food consumption was marginally lower than control in many occasions throughout the study. In all other groups mean food consumption was considered to be comparable to the controls throughout the study.

Iris mydriatis and an abnormal pale colour of fundus of the retina was noted in 4/48 and 3/48 high-dose females, respectively, compared to 0/30 in controls. In addition, higher incidences of lens opacity was observed at this dose level in comparison to the controls. However, lens opacity is a common finding in rats of this age and strain, and the values were well within the historical control data, while the value in the control group was particularly low and outside the historical control data of the test lab. Therefore this change was considered to be not treatment-related.

The transient haematological changes observed were considered to be not treatment-related in view of their low magnitude and transient occurrence.

Slightly lower total bilirubin concentrations were observed at 2000 ppm in both sexes. Slightly higher mean total cholesterol was observed throughout the study in high-dose females. No relevant changes were noted in other groups and at other dose levels.

No treatment-related findings were observed at urinalysis.

At the interim sacrifice and at the end of the study duration, mean liver to body weight ratios were statistically significantly higher when compared to controls at 2000 ppm in both sexes. Enlarged and pale liver was noted in 3/10 high-dose males at interim sacrifice and was considered to be associated with the treatment. At the completion of the 2-year study period white foci in the lung were noted in 21/46 of high-dose females, which were considered to be associated with the treatment. Also higher incidence of ovarian cysts was noted in 18/46 females, when compared to 8/29 in the controls. However, as microscopically there were no differences in terms of percentages in ovarian cysts between the control group (18/29, 62%) and high-dose group (31/46, 67%), this finding was considered to be not treatment-related.

At the interim sacrifice, higher incidences of eosinophilic and tigroid foci of altered hepatocytes were observed in high-dose males. Centrilobular hypertrophy was observed in both sexes at 2000 ppm and also at 400 ppm in 2/10 males (dose-related effects). However, in the absence of any increase of incidences of foci of alterations or hepatocellular macrovacuolation, this change at 400 ppm was considered to be not an adverse effect. Centrilobular hepatocellular macrovacuolation and lower incidences of periportal hepatocellular vacuolation were noted in both sexes at 2000 ppm. In the thyroid gland, colloid alteration was found to be increased in incidence and severity in both sexes at 2000 pm and in males at 400 ppm. At the terminal sacrifice, higher incidences of eosinophilic, mixed and tigroid foci of altered hepatocytes were observed in males at 2000 ppm. Centrilobular hypertrophy and higher incidences of centrilobular hepatocellular macrovacuolation were observed in both sexes of high-dose group. Higher incidences of hepatocellular brown pigments and brown pigments in Kupffer cells, higher incidence of interstitial mononuclear cell infiltrate and lower incidences of periportal hepatocellular macrovacuolation were noted in high-dose females. No adverse effects was noted in both sexes at 400 ppm; there was only minimal centrilobular hypertrophy in 6 male animals without any increase of foci of alteration or hepatocellular macrovacuolation.

In the lung higher incidences of foamy macrophages, chronic interstitial inflammation and perivascular inflammation were observed in high-dose females at the terminal sacrifice.

In the thyroid, increased incidences of colloid alteration were noted in males at 2000 and 400 ppm. The effect at 400 ppm was not considered to be adverse, as increased incidence of colloid alteration occurs naturally in aging rats and was not associated with relevant follicular hypertrophy at this dose level.

No neoplastic lesions were observed at any dose levels.

Historical control data are provided only for ophthalmologic findings and are based on selected 2-year studies performed in-house between February 2005 and February 2008.

Acceptability

The study is considered acceptable.

Conclusions

No neoplastic lesions were observed in the study at any dose level. The NOAEL for carcinogenicity was set at the highest dose level of 2000 ppm, equal to the average daily intake of 80.9 and 120 mg/kg bw/day over 104 weeks for male and female rats, respectively.

Based on effects in the liver and in a less extend in the thyroid and lung (females), the NOAEL for general toxicity was set at 400 ppm in diet, equal to the average daily intake of 15.8 and 22.5 mg/kg bw/day over 104 weeks for male and female rats, respectively (18.5 and 25.3 mg/kg bw/day, respectively, over 52 weeks).

**: p≤0.01

No test-substance related mortality or clinical signs were observed. Reduced body weight was observed in both sexes at the highest dose level (statistically significant in males). Mean cumulative body weight gain over the whole study period was also significantly reduced in males and females of the high-dose group and was 19% lower than in controls in males and 13% lower than in controls for females. Mean body weight gain over the whole study period was also slightly reduced in mid-dose

animals of both sexes (not statistically significant). Food consumption was decreased on several occasions throughout the study in high-dose females (average 3% below controls).

At the interim sacrifice, absolute kidney weight and kidney to brain weight ratio were 13 to 15% lower than controls in high-dose males (statistically significant). Mean brain to body weight ratio was 9% higher than controls in high-dose males ($p \leq 0.05$), but this effect was considered to be related to the decreased body weight. At the macroscopic observation, no treatment-related changes were noted in either sex at any dose level. Histopathology was not performed at the interim sacrifice.

At the terminal sacrifice, absolute and relative liver weights were 9 to 14% higher than controls in high-dose males ($p \leq 0.01$). Relative liver weight was also increased in high-dose females ($p \leq 0.01$), but this effect was considered to be related to the reduced body weight. Statistically significantly reduced absolute and relative kidney weights were observed in high-dose males. Relative brain weight was slightly higher than controls in both sexes of the high-dose group (+5% in males and +7% in females, $p \leq 0.01$), but this effect was considered to be related to the reduced body weight.

At the macroscopic observation, atrophic/small kidneys were noted in 5/42 high-dose males (in comparison to 0/38 in controls). At histopathological examination increased incidence of centrilobular hepatocellular vacuolation was noted in high-dose males (statistically significant), whilst a decreased incidence of periportal hepatocellular macrovacuolation was noted in high-dose females (statistically significant). Not statistically significant increase in the incidence of centrolobular hepatocellular vacuolation was also noted in mid-dose males. These changes in the liver were considered to be treatment-related but not adverse due to the lack of associated degenerative changes. In the kidney, decreased incidence and severity of bilateral basophilic tubules, focal cortical mineralization and corticoepithelial vacuolation were noted in high-dose males (all statistically significant). These changes in the kidney were considered to be treatment-related but not adverse, as they occurred with lower incidence and severity than in control animals).

No neoplastic changes were evidenced at any dose level in either sex.

Historical control data for histopathological findings were provided from 11 in-house studies with C57BL/6J mice performed in the period October 2000 – March 2007.

Acceptability

The study is considered acceptable.

Conclusions

No neoplastic changes were evidenced in any group at any dose level. The NOAEL for carcinogenicity was set at the highest dose level of 1500 ppm, equal to the average daily intake of 224 and 263 mg/kg bw/day over 18 months for male and female mice, respectively.

Based on effects in the liver and in de kidney (male) the NOAEL for general toxicity was set at 300 ppm in diet, equal to the average daily intake of 45 and 53 mg/kg bw/day over 18 months for male and female mice, respectively.

B.6.5.2 Summary

In Table 6.5.2.1 the results of the chronic toxicity and carcinogenicity studies with the test substance are summarised.

Table 6.5.2.1 Oral chronic toxicity and carcinogenicity studies

Duration (weeks)	Species	NOAEL (mg/kg bw/d)	LOAEL (mg/kg bw/d)	Critical effects	Reference
104	rat	15.8	80.9	Effects on liver, thyroid and lung	[redacted], 2012
78	mouse	43	224	Effects on liver and kidney	[redacted] 2012

In a two-year toxicity/carcinogenicity study with rats, effects in the liver and in a less extend in the thyroid and lung (females) were observed in the 2000 ppm dose group. The NOAEL for general toxicity was set at 400 ppm in diet, equal to the average daily intake of 15.8 mg/kg bw/d. No neoplastic lesions were observed in the study at any dose level.
In an 18-months carcinogenicity study with mice, effects in the liver and in de kidney (male) were observed in the 1500 ppm dose group. the NOAEL for general toxicity was set at 300 ppm equal to the average daily intake of 45 mg/kg bw/day.

Study design

The study was performed in order to determine appropriate dietary levels for a definitive (guideline) two-generation reproductive toxicity study with BYI 02960. In this study, BYI 02960 was administered continuously in the feed to the Wistar rat (10 animals/dose/sex) at nominal dietary concentrations of 0, 200, 700, and 2000 ppm. All test diets (including control) were available for *ad libitum* consumption; the homogeneity and stability of BYI 02960 as a dietary admixture was confirmed. Body weight and food consumption determinations and detailed clinical examinations of each animal were conducted weekly throughout the study, as well as, an evaluation of multiple reproductive parameters. All animals placed on study were subject to a postmortem examination, which included documenting and saving all gross lesions, weighing designated organs and, collecting representative tissue specimens. Micropathology was not performed on any tissue collected in this study.

The mean values of the actual substance intake from the intended test material dose levels for the parental generation are shown in Table 6.6.1-1.

Table 6.6.1-1 Mean values of the actual substance intake by parental animals during premating, gestation and lactation

Phase of Study	200 ppm in mg/kg/day[a]	700 ppm in mg/kg/day[a]	2000 ppm in mg/kg/day[a]

[b] Before standardization (culling)
[c] After standardization (culling)
* Statistically different from control, $p \leq 0.05$

There were no test substance-related mortalities or clinical observations observed during the course of the study at any dietary level tested.

In males, no effects on body weight were observed at any dose level. In females, declines in absolute body weight were observed during premating in 2000 ppm group (9.4% decline when compared to controls), during gestation in 700 and 2000 ppm groups (4.5% and 11.3% respectively, value in 2000 ppm group reached statistical significance) and during lactation in 700 and 2000 ppm groups (10.6% during days 14-21 in 700 ppm group, 10.2% during days 0-21 in 2000 ppm groups, both statistically significant).

In males a very slight decrease in body weight gain during premating was observed in the 2000 ppm dose group (9.3% decline when compared to controls). In females, declines in body weight gain were noted during premating in 700 and 2000 ppm group (12.3% and 33.4%, respectively). Food consumption was decreased 8.8% in females at 2000 ppm during premating. No further changes on body weight gain and food consumption were noted.

There were no test substance-related effects on any reproductive parameter (e.g. mating, fertility, or gestation indices, days to insemination, gestation length, or the median number of implants) at any dietary level tested.

In males, equivocal increases in liver weights were observed in both the 700 and 2000 ppm dose groups. In females, test substance-related decreases in absolute and relative spleen weight were observed in the 2000 ppm dose level.

There was no test substance-related effects observed on the viability of the pups after delivery at any dietary level tested. No test substance-related clinical observations were observed at any dietary level tested. Declines in absolute pup weight were observed beginning post-natal day (PND) 14 and continuing to PND 21 in the 700 and 2000 ppm dietary groups with significance only observed for the females. Body weight gain for the males and females was declined in both the 700 and 2000 ppm dose group (9.7% and 10.8%, respectively).
Significant changes in brain weight in the 2000 ppm dose group and slight changes in the 700 ppm dose group were observed (decreased absolute and increased relative) and are considered to be secondary to body weight declines observed in the pups at these same dose groups. There were no test substance-related gross necropsy findings observed at any dietary level tested.

Historical control data were obtained from reproduction studies performed in the same test laboratory in the period of 1998-2008 in the Wistar rat.

Acceptability
The study is considered acceptable.

Conclusion
The parental systemic LOAEL is 700 ppm (60.0 mg /kg bw/day females), based on decreased body weight, decreased body weight gain, alterations in food consumption during premating, and decreased spleen weights in females. The parental systemic NOAEL is 200 ppm (17.5 mg /kg bw/day).
The reproductive NOAEL is 147.5 mg /kg bw/day based on no reproductive findings observed at the highest dose tested.
The offspring LOAEL is 700 ppm (60.9 mg /kg bw/day). The LOAEL is based on maternal effects leading to secondarily-mediated effects on pup weight, pup weight gain, and organ weight changes (brain). The offspring NOAEL is 200 ppm (17.5 mg /kg bw/day).

Study 2

Data requirement:
Applicant to provide clarification on the possible endocrine-mediated MoA of flupyradifurone. The information *embedded in column 3 of the reporting table should be included.*

In the rat two-generation reproduction study conducted on Flupyradifurone changes were observed in offspring at the high dietary concentration of 1800 ppm. Effects seen on PPS and VO, two well-established markers of pubertal development, included a statistically significant delay (PPS) and a slight, non-statistical delay (VO) in F1 generation animals. In addition, variations in brain, thymus, and spleen weights in offspring of

the 500 ppm (F2 generation) and 1800 ppm (F1 and F2 generations) dose groups were also observed. A slight, albeit significant, decrease in median implantation sites (and thus decrease in litter size) in the F1-generation was observed with 1800 ppm Flupyradifurone. It is the position of both Bayer CropScience (BCS) and the performing laboratory that the aforementioned effects are likely a result of treatment-induced reductions in BW and BWG rather than a direct, endocrine-mediated MOA. The discussion that follows defends this position for each of the observed changes in the context of available data on Flupyradifurone and in the publicly available literature (see below). This position from BCS should be taken into account during the expert consultation.

Preputial Separation

Toxicity testing guidelines for the rat two-generation reproduction toxicity study require that systemic toxicity is evident at the highest dose level, and dose levels should be chosen with the aim to induce some reproductive and/or systemic toxicity, but not death or severe suffering (OECD 416; OCSPP 870.3200). As such, effects on BW (reductions >10%) are the most common effects noted at maximum tolerated dose levels, and it is reasonable that delays in preputial separation may be observed as a result of general systemic toxicity rather than a consequence of an endocrine-mediated MOA (Stump et al., 2012). In the present study, animals exposed to 100 ppm or 500 ppm.

Flupyradifurone achieved PPS in a time latency similar to concurrent controls and well within historical control data for Wistar Han rats in the performing laboratory (see Appendix 1). At the high dietary level of 1800 ppm, however, a statistically significant delay in PPS (3.9 days) was observed compared to controls (Table 1). The observed delay in PPS in animals at 1800 ppm is likely due to significant BW loss and food consumption and not a result of an endocrine MOA associated with delayed PPS.

N	35	35	35	35

Statistically significant compared to control animals (p≤0.05).

A recent study concluded that while treatment-related delays in PPS may be indicative of specific anti-androgenic activity, impaired growth could also alter the onset of puberty (Melching-Kollmuss et al., 2014). The mean BW at the day of complete PPS was similar between the control animals (178 g) and 1800 ppm group (180 g) (Table 1, Figure 1), however, the mean BW at PND 21 was significantly decreased (-12.5%) compared to control animals (see Appendix 2); BW at PND 21 is often used as a covariate for evaluating the age at complete PPS (Stoker et al., 2000b). This significant decrease in BW at PND 21 was accompanied by significant

decreases observed in maternal BW of the 1800 ppm group throughout gestation (GDs 0, 6, 13, and 20; see Appendix 3). As other sensitive anti-androgenic parameters investigated in this study such as male fertility, male reproductive organs (weights and histopathology) and sperm parameters (count, motility, or progressive sperm) were not affected at any dietary level of Flupyradifurone, it is likely that the effect on PPS was due to a non-specific effect linked to overt toxicity with decreased BW and retarded growth.

Figure 1: Mean Body Weight at Day of Complete Preputial Separation

The influence of BW loss on reproductive endpoints has also been evaluated in rats by diet restriction. A significant delay in PPS (2.1 days) was observed in Wistar rats that were food-restricted and exhibited a mean body weight loss of 13% (Stoker et al., 2000), and Ashby and LeFevre (2000) reported that the day of PPS was dependent upon the BW at weaning, and not specifically to BW at the time of complete PPS. Consistent with these diet restriction studies, P-generation females in the high dietary dose group exhibited significantly reduced food consumption throughout premating, which is likely responsible for the observed decreases in BW and BWG in these dams and delayed PPS in their male offspring. By comparison, direct-acting anti-androgens do not inhibit food consumption or slow growth (Anderson et al., 1995), but they delay PPS and reduce the weights of the ventral prostate, seminal vesicle, epididymides, Cowper's glands, and levator ani plus bulbocavernosus muscles (Stoker, 2000b; Owens et al., 2006). Compounds that act as anti-androgens may also delay PPS via hypothalamic-pituitary or steroid hormone synthesis disruptions (for review see Stoker et al., 2000b), but in these cases, changes in testicular weights, testosterone and/or luteinizing hormone concentrations (not evaluated in the current study), and changes in accessory sex gland tissue weights would have accompanied the observed delay in PPS. Furthermore, anti-androgens such as vinclozolin, can decrease male pup anogenital distance (AGD) to an extent similar to female pups (Gray et al., 2001). None of these anti-androgenic changes were observed in the two-generation reproduction study or the rat developmental neurotoxicity study (Gilmore, 2012) conducted on Flupyradifurone.

These data strongly support the conclusion that the delay in PPS observed in F1-generation males after exposure with high dietary concentrations of Flupyradifurone is due to significant BW loss and reduced food consumption and BWG over the exposure period, and not due to an endocrine-mediated MOA.

Vaginal Patency

F1-generation females showed a slight, non-significant delay in VO (1.0 day) in animals in the 1800 ppm dietary concentration group. The mean for complete VO was 34.8 days for the control females and 35.8 days for the high dietary level females (Table 2, Figure 2). It should be noted, however, that the day means to complete VO were within the historical control range (33.4 – 36.7 days, see Appendix 1) for all dietary levels of Flupyradifurone. The F1-generation females achieved VO with significantly reduced BW and BWG (-16.6% and -19%, respectively, compared to controls) during lactation, and no other disruptions in estrogen sensitive endpoints (i.e. tissue weights, estrous cyclicity, histopathological analysis, mating parameters) were observed in the remainder of the study. Furthermore, no other estrogen sensitive parameters were affected by Flupyradifurone in the rat developmental neurotoxicity study (Gilmore, 2012), the developmental toxicity studies (Langrand-Lerche, 2010 ; Kennel, 2012), or the chronic toxicity/carcinogenicity studies (Garcin, 2012 ; Kennel, 2012). Therefore, the slight delay of 1 day in VO after high dietary exposure to Flupyradifurone is most likely the result of decreased BW and BWG during lactation, as well as decreased maternal BW and BWG throughout premating, gestation, and lactation. Delays in VO, concurrent with observations of delayed PPS in males, is understood to indicate a general growth delay, rather than an endocrine MOA (Stump et al., 2012). A slight, but statistical, decrease in the number of estrous cycles in the F1-generation was observed, but is also attributable to BW loss, as irregular cycles are often noted in the immediate post-pubertal period (Goldman et al., 1985). Taken together, these points indicate that the non-statistically significant delay VO is not endocrine-mediated and is of no biological significance.

Figure 2 : Mean Body Weight at Day of Complete Vaginal Patency

Organ Weight Changes in Pups

Organ weight changes in pups were observed in brain, thymus, and spleen in pups exposed to 1800 ppm Flupyradifurone. Similar to changes observed in PPS and VO, the pup organ weight changes were due to significant BW loss over the exposure period, and not due to an endocrine MOA. In F1-generation pups, birth weight was significantly decreased in both sexes, and an overall decrease in BWG throughout lactation was observed in F1- (-13.7%) and F2-generation (-13.8%) pups at the high dietary level. Pup terminal BWs were also decreased in males (-10%) and females (-12%). In both sexes and generations, absolute brain weights were decreased, while brain weight relative to BW was increased. A similar trend was observed thymus weights, while absolute spleen weights were decreased in F1 males and both sexes in the F2 generation.

Brain weights (see Appendix 4):

In F1 pups on PND21, a slight decrease in absolute brain weight was observed in males (-3.93%) and females (-3.3%) at 1800 ppm (only one male was outside the control range) and a slight increase in brain weight to body weight ratio was observed (+9.5% in males and +9.07% in females) due to lower body weight. Nine males from 7 litters and 12 females from 7 litters were outside the control range but they had lower body weight compared to control animals.

In F2 pups, a statistically significant decrease in absolute brain weight was observed in females only (-3%) with only one animal outside the control range. A statistically significant increase in brain weight to body weight ratio was observed in males (+11.5%) with 6 animals from the same litter outside the control range due to lower body weight and in females (+11.4%) with only one animal outside the control range.

Thymus weights (see Appendix 5):

F1 pups at 1800 ppm: Statistically significant thymus weight changes were observed in males for absolute weights (-11.3%, all animals within control range) and in females for thymus weight to body weight ratio (+6.8% with 3 animals outside the control range due to lower body weight).

F2 pups at 1800 ppm: A statistically significant decrease in absolute thymus weight in females (- 10.96%) was noted with 12 animals from 5 litters outside the control range due to lower body weight. No significant changes were observed in thymus weight to body weight ratio.

Spleen weight (See Appendix 6):

F1 pups at 1800 ppm: A statistically significant decrease in absolute spleen weight was observed in males only (-17.98%) with all animals within the control range and no significant effect on spleen weight to body weight ratio.

F2 pups at 1800 ppm: A statistically significant decrease in absolute spleen weight was observed in both males (-14.98%) with 6 animals from one litter outside the control range due to lower body weight and females (-15.48%) with 6 animals from 3 litters outside the control range due to lower body weight. No significant effect on spleen weight to body weight ratio in both sexes.

The organ weight changes and reduction in pup terminal BWs seen in the present study are consistent with changes in the brain, thymus, and spleen observed in a food restriction reproduction study in which animals were given 30% less food daily relative to control groups (Carney et al., 2004). Animals receiving 30% less food (equivalent to 6-19% BW decrease) showed similar reductions in absolute organ weights with concomitant increases in relative organ weights in both male and female rats ; animals receiving only 10% less food, which did not change BW, showed no organ weight changes compared to control groups (Carney et al., 2004). Animals receiving 30% less food exhibited BW reductions similar in magnitude to those found in animals exposed to the high dietary level of Flupyradifurone in the two-generation reproduction study. These data support the notion that significant reductions in BW can influence organ weights. In addition, no microscopic changes were observed in the brain, thymus, or spleen in animals of either sex in the Flupyradifurone two-generation reproduction study. The rat DNT study (Gilmore, 2012) and rat subchronic neurotoxicity study (Garcin, 2011) conducted with Flupyradifurone did not produce any brain weight changes up to the high dietary levels of 1200 ppm and 2500 ppm, respectively. In both studies, BW and BWG declines were not as severe in magnitude as those seen in the two-generation reproduction study, supporting the conclusion that the organ weight changes observed in the reproduction study are likely due to reductions in BW and BWG. In a rat immunotoxicity study conducted with Flupyradifurone (Repetto, 2011), significant decreases in the absolute weight of the spleen and thymus were observed, but relative weights were unchanged for both organs. These results are consistent with other repeat-dose dietary toxicity studies conducted with Flupyradifurone and support the conclusion that the observed organ weight changes in pups are likely due to general systemic toxicity and decreased BW and BWG of the animals. The lack of response in endocrine-sensitive tissues in both sexes further supports these organ weight changes are due to significant decreases in BW and not an endocrine-mediated event.

Reduced Number of Implantation Sites

A slight, albeit significant, decrease in median implantation sites (and thus decrease in litter size) in the F1-generation was observed with 1800 ppm Flupyradifurone. This effect, however, was not observed in the P0-generation dams (Table 3), and the total number of implantation sites between the P0- and F1-generations in the control (311 and 305, P0 and F1, respectively) and high dose (289 and 281, P0 and F1, respectively) are similar. This slight decrease is likely due to the decreased BW in the P0 females, which was observed as early as day 7 after initiation of exposure. Significant BW decreases were maintained for the duration of the study, including the F1 females at birth, and continuing through mating and gestation of the F2 animals (see Appendix 3). Exposure to exogenous chemicals that produce a reduction in the amount of BW gained during the first 9 days of pregnancy is an indication of the inherent toxicity of the chemical and may contribute to maternal toxicity and pregnancy loss (Cummings et al., 2000). No other effects were noted in female organ weights or histopathology in the two-generation reproduction study. Developmental toxicity studies in rats (Langrand-Lerche, 2010) and rabbits (Kennel, 2012) for Flupyradifurone did not show any significant decreases in the number of implantation sites in dams that showed a significant decrease in BW, nor in any other changes in reproductive indices, tissue weights, or histopathology. Taken together, the data supports that this finding was due to a decreased BW and not an endocrine-mediated MOA.

Table 3: Total Number of Implantation Sites Across Generations and Dietary Levels of Flupyradifurone

Summary and Conclusion

The two-generation reproduction study conducted in rats with Flupyradifurone reported changes in a few endpoints that are known to be influenced by endocrine MOAs. In light of this, EFSA questioned whether observed delays in PPS and VO, pup organ weight changes, and reductions in implantation sites observed at the highest dietary level of 1800 ppm might be endocrine mediated. Thorough evaluation of the available data on Flupyradifone and the peer-reviewed literature confirmed the initial position of BCS and the performing laboratory that these changes were secondary to decreases in BW and BWG. Several publications reporting studies that utilized food restriction to evaluate the effect of reduced BW and BWG on developmental and reproductive endpoints support this position. The mammalian toxicity database for Flupyradifurone does not indicate any anti-androgenic or anti-estrogenic activity, two known endocrine-mediated MOAs. Thus, the changes seen in the endpoints in question appear to occur secondary to

overt toxicity associated with exposure to Flupyradifurone as evidenced by reductions in BW and BWG throughout all stages, including critical periods of development, of the two-generation reproduction study.

1800 ppm	Males	0.193** ± 0.0082 (29)	[0.070 - 0.327]	6 animals outside the control range from one litter due to lower body weight - No significant effects on spleen weight to body weight ratio
	Females	0.191** ± 0.0088 (29)	[0.074 - 0.348]	6 animals outside the control range from 3 litters due to lower body weight - No significant effects on spleen weight to body weight ratio

General Comment

Effects unrelated to the endocrine system observed after chemical treatment often confound the interpretation of results of endpoints evaluated in standard reproductive toxicology studies (Carney et al., 2004; Laws et al., 2007; Marty et al., 2007; Laws et al., 2000; Stoker et al., 2000a; for review see Stoker et al.,

2000b). For example, significant body weight loss, altered feed intake, and stress responses can contribute to changes in study endpoints that may be inaccurately attributed to an endocrine-mediated mechanism. Several peer-reviewed publications report studies that have been conducted utilizing food restriction, resulting in varying degrees of BW loss, to determine the influence of BW reduction on *in utero* and postnatal developmental endpoints (Carney et a., 2004; Chapin et al., 1993; Laws et al., 2000; Laws et al., 2007; Marty at al., 2007; Stoker et al., 2000a). Endocrine-related endpoints evaluated in these studies include PPS and sperm parameters in males, VO and estrous cyclicity in females, and organ weights and hormone concentrations in both sexes.

Study design

The study was performed in accordance with OECD guideline 416.

The mean values of the actual substance intake from the intended test material dose levels for the P and the F1 generation are shown in Table 6.6.1-8.

Table 6.6.1-8. Mean values of the actual substance intake by parental animals during premating, gestation and lactation

Phase of Study	100 ppm in mg/kg/day[a]	500 ppm in mg/kg/day[a]	1800 ppm in mg/kg/day[a]
Premating (P-gen) - Male	6.6	32.5	117.4
Premating (F_1-gen) - Male	6.4	32.0	122.1
Mean P- and F_1-gen - Males	**6.5**	**32.3**	**119.8**
Premating (P-gen) - Female	7.7	38.7	137.0
Premating (F_1-gen) - Female	7.8	39.6	143.4
Mean P- and F_1-gen - Females	**7.8**	**39.2**	**140.2**
Gestation (P-gen) – Female	6.9	34.3	134.0
Gestation (F_1-gen) – Female	7.0	36.6	168.8
Mean Gestation P and F_1	**7.0**	**35.5**	**151.4**
Lactation (P-gen) - Female	7.8	37.4	140.4
Lactation (F_1-gen) - Female	7.7	42.2	160.3
Mean Lactation P and F_1	**7.8**	**39.8**	**150.4**

[a] Individual values were based on the means for each particular phase

Results

The results of the study are summarised in table 6.6.1-9. Additionally, data on the mean body weight and food consumption during premating, gestation and lactation, estrous cycle, sperm measures, reproductive performance, litter parameters and pup weights are presented in tables 6.6.1-10 – 6.6.1-18.

[d] GAIN taken from Table 20 in the study report * Statistically different from control, $p \leq 0.05$ ** Statistically different from control, $p \leq 0.01$

Parental animals (P and F1 adults)

At the highest dose level, statistically significant decreases in body weight were observed in parental P and F1 females during premating, gestation and lactation. In F1 males, at the highest dose level significant decreases in body weight were observed beginning on Day 0 and continued throughout exposure. Statistically significant decreases in body weight during premating, gestation and lactation were observed also in F1 females at the mid-dose level however the weight loss was less than 10%.

Body weight gains were decreased in P and F1 females during premating and gestation in the high-dose groups, and non significant during pre-mating in the mid-dose group (21% for P-generation females and 16% for F1 generation females). Also increased food consumption was observed in the high-dose F1 females during gestation.

In the high-dose P males, increased absolute and relative liver weight (9% relative to controls) and increased absolute thyroid weights (13-21% relative to controls) were observed. Minimal centrilobular hypertrophy of the liver was observed in the high-dose P males, correlated with the increased liver weights. No other organ weight changes and microscopic changes were noted at any dose levels in both P and F1 generations.

No adverse effects on reproductive performance, sperm parameters or oestrous cycle were noted in P generation at any dose level. In the F1 generation, a significant decrease in the number of oestrous cycles was observed in the high-dose females (see Table 2.6). This finding paralleled the significant weight loss observed in these females. A statistically significant decline in the total number of implantation sites was also observed in the high-dose F1 females (see Table 2.8). No clear dose-response was obvious. These findings are considered to be secondary to the maternal toxicity, as evidenced from the significant weight loss, rather than true adverse reprotoxic effects.

Off-spring (F1and F2 pups)

No effects on the litter size, pup viability, sex ratio and lactation index were observed in F1 pups at any dose level. A slight decrease in the litter size was noted in the high-dose F2 pups (see Table 2.9). This decrease paralleled the reduced body weight gain during gestation and a decreased number of implantation sites in the high-dose F1 females. There were no substance-related effects on the pup viability, sex ratio and lactation index.

A significant decrease in birth weight was observed (8.2% compared to the controls) in the F1 pups of the highest dose level. This decrease continued and increased by magnitude by post-natal day (PND) 21. A significant delay in preputial separation and a slight nonstatistical delay in vaginal patency were observed in parallel with the decreased pup weight exhibited during lactation in the same dose group. Reduced absolute and relative brain (statistically significant), thymus (statistically significant only in males) and spleen weights (statistically significant) were observed in high-dose F1 pups, but were

considered to be secondary to the decreased body weights at the same dose level and not a direct test substance effect.

The body weights at birth were comparable to controls in the F2 pups at all dose levels. Pup weight declines were observed beginning on PND 7 (declined 8.1%) and continued to Day 21 (declined 12.5%) at the high-dose level and on PND 14 to Day 21 at the mid-dose level. No effect on anogenital distance was observed in the F2-generation pups at any dose level. Reduced absolute and relative brain (statistically significant only in females), thymus and spleen weights (statistically significant) were observed in high-dose F2 pups, but were considered to be secondary to the decreased body weights at the same dose level and not a direct test substance effect. Significantly reduced thymus weight was also observed in mid-dose F2 female pups.

Acceptability

The study is considered acceptable.

Conclusions

A significant decrease in body weight, but <10% was observed in the mid-dose of the F1 females and a non significant decrease in body weight gain was found in the parental animals (21 % in females) and the F1 animals (16 % in females). Therefore the parental systemic LOAEL is considered 500 ppm (32 mg/kg bw/d) based on decreased body weight gain in females. The parental systemic NOAEL is 100 ppm (7.7 mg/kg bw/d). ~~Therefore the parental systemic LOAEL is considered 1800 ppm (117.4 mg BYI 02960/kg bw/day) based on increased liver and thyroid weights, and minimal centrilobular hypertrophy in males decreased body weight (>10%)(premating, gestation, and lactation), body weight gain (premating; P and F_1). The parental systemic NOAEL was 500 ppm (32.0 mg BYI 02960/kg bw/day).~~

The reproductive NOAEL was 500 ppm (34.3 mg BYI 02960/kg bw/day females) based on decreased estrous cycle number, litter size, and the number of implants observed in the F_1 generation at the highest dietary level tested (LOAEL = 1800 ppm (134.0 mg BYI 02960/kg bw/day in females).

A significant decrease in body weight, but <10% was observed in the mid-dose of the F2 pups. The offspring LOAEL is therefore 1800 ppm (134.0 mg BYI 02960/kg bw/day) based on maternal effects leading to secondary effects on pup weight, and physical development. The offspring NOAEL is 500 ppm (34.3 mg BYI 02960/kg bw/day).

Expert consulatation 2.8

With regard to the parental toxicity, the RMS proposed a revised NOAEL of 100 ppm (equivalent to 6.4 mg/kg bw per day), considering significant decrease in body weight (<10% observed in the mid-dose of the F_1 females) and a non-significant decrease in body weight gain found in the parental animals (21% in females) and the F_1 animals (16% in females). This was agreed by the experts.

The reproductive NOAEL was set at 500 ppm (equivalent to 32 mg/kg bw per day) based on decreased oestrous cycle number, litter size, and the number of implantation sites observed in the F_1 generation. This was agreed by the experts.

The offspring NOAEL was set at 500 ppm based on significant decrease in pup weight in F_1 generation (21%). Considering the effect in the F_2 pups on body weight, the experts agreed on a NOAEL of 100 ppm for the pup development (reduced weight gain).

Some findings could be considered as endocrine-mediated, even though the notifier claimed that they were within historical control data. It was noted that historical control data were not fully appropriate and more weight should be given to the concurrent control data.

The experts agreed that there was not sufficient evidence demonstrating that the mode of action was not endocrine-mediated and set a data gap for level 2 studies according to OECD Conceptual Framework.

a Data obtained from Table 12 in the Tables and Appendices section of the study report.
 # : Statistical analysis was conducted on this observation (App M)
*** Statistically different (p≤ 0.05) from the control.**
**** Statistically different (p≤ 0.01) from the control.**

There were no mortalities during the study. At 150 mg/kg bw/day, increased salivation was noted in 20/23 animals on one or several occasions between gestation days (GD) 11 and 21 and soiling around the mouth was observed in 1/23 females on GD 21.

In the high-dose females a mean maternal body weight gain and the maternal corrected body weight change were decreased between GD 6-21 (not statistically significant). The mean body weight changes were significantly lower than controls by 14 to 91% on all intervals between GD 6 and GD 18 (p ≤ 0.01). The food consumption was significantly decreased between GD 6 and 12. At 50 mg/kg bw/day the mean maternal body weight gain was reduced by 49% between GD 6-8, and the mean maternal body weight change was significantly lower than controls by 23% between GD 6 and GD 10. The mean food consumption was reduced by 8% between GD 6-8 (p ≤ 0.05). No treatment-related body weight changes were observed in the low-dose group.

At 150 mg/kg bw/day the mean absolute liver weight was 13% higher than in the controls (p ≤ 0.01). No other treatment-related findings were observed at the macroscopic examination at any dose level.

The pregnancy rate was at least 96% in all dose groups and was unaffected by treatment. The number of live fetuses, the number of implant sites per dam, the percentages of pre and post

implantation losses, the number of early and late resorptions, the fetal death status and the percentage of male fetuses were unaffected by treatment in any dose group.

At 150 mg/kg/day, mean fetal body weights for combined sexes and females were reduced by 2 to 3%, compared to the controls (not statistically significant). No other treatment-related changes on fetal body weights were noted.

There were no treatment-related malformations or variations noted at the fetal external examination and fetal visceral examination. At 150 mg/kg bw/day, the incidence of parietal and hyoid centrum incomplete ossification were statistically significantly higher than in the control group ($p \leq 0.01$). No clear dose-response was obvious. The incidence of unossified 7th cervical centrum and 5th sternebra incomplete ossification were also higher in 150 mg/kg bw/day group than in the controls, but the incidence was not statistically significant and the observed values within the in-house historical control data. The incidence of the short 13th costal cartilage was also higher in the 150 mg/kg bw/day group than in the controls and was outside the in-house historical control data, but as the observation was noted unilaterally only and the incidence was low, the finding was considered to be not treatment-related.

The historical control data were generated from fifteen in-house Sprague-Dawley Crl:CD (SD) rat studies conducted between 2001-2008.

Conclusions

Minimal maternal toxicity was observed at the high-dose level, manifested as decreased body weight gain and reduced food consumption. The mean absolute liver weight was increased in the high dose group. Based on these findings the NOAEL for maternal toxicity was set at 50 mg/kg bw/day.

The increased incidence of parietal incomplete ossification showed no dose response, the unossified cervical centrum and the incomplete ossification of the sternebra was within the historical background. A increase of a short costal cartilage was seen at the high-dose. Based on these findings, the NOAEL for developmental toxicity was set at 50 mg/kg bw/day.

STUDY 2

Characteristics

reference	:	[redacted] 2012	exposure	:	Gestation days (GD) 6-20
type of study	:	Complementary maternal tolerability study	doses	:	0, 20 and 30 mg/kg bw/day
year of execution	:	2011/2012	vehicle	:	0.5% aqueous methylcellulose 400
test substance	:	BYI 02960 (batch number 2009-000239; purity 96.2%)	GLP statement	:	Yes
route	:	Oral (gavage)	guideline	:	None (complementary tolerability study); however, the in-life portion of the study was conducted according to OECD guideline 414.
species	:	Rat, Sprague-Dawley Crl:CD (SD)	acceptability	:	Acceptable
group size	:	23/sex/dose	**NOAEL**maternal toxicity	: : :	30 mg/kg bw/day

Characteristics

The study was performed to provide additional information on the maternal tolerability of BYI 02960 and to determine more precisely the NOAEL for maternal toxicity. Groups of 23 sperm-positive female Sprague-Dawey rats were exposed to BYI 02960 by oral gavage from gestation day (GD) 6 to 20, the sperm-positive day being GD 0. The doses given were 0, 20 and 30 mg/kg bw/day in aqueous solution of 0.5% methylcellulose 400. Clinical observations were recorded daily. Maternal body weights were recorded for all females on GD 0, 6, 8, 10, 12, 14, 16, 18 and 21. Food consumption was also measured for all the females during the intervals GD 1-6, 6-8, 8-10, 10-12, 12-14, 14-16, 16-18 and 18-21. At scheduled sacrifice, on GD 21, a macroscopic examination of the visceral organs was performed, the gravid uterine weight was recorded and the live fetuses were euthanized. In addition, the liver was weighed at scheduled sacrifice for all pregnant females. A portion of liver was retained in 10% neutral buffered formalin from all females on study for possible histological examination. Specimens were not examined and are retained in the archives.

Results

The results of the study are summarized in Table 6.6.2-5. Additional information on maternal body weight gain and caesarean section observations is provided in Tables 6.6.2-6 – 6.6.2-7.

No. Animals pregnant	21	23	23
Pregnancy rate, %	91	100	100
No. Animals non-pregnant	2	0	0
Maternal wastage			
No. died (total)	0	1	0
No. died pregnant	0	1	0
No. died non-pregnant	0	0	0
No. premature delivery	0	0	0

Data obtained from Table 1 and Appendix G in the Tables and Appendices section of the study report.

No treatment-related mortality or clinical signs were observed in the study. One animal of the mid-dose group died on GD 20 after having been dosed. Necropsy revealed red dark lungs and presence of foam in lungs and trachea, indicating of a gavage error. Body weight parameters and food consumption were unaffected by treatment. There were no treatment-related macroscopic findings at necropsy and no changes in liver weights at any dose level.

Historical control data on the maternal parameters were obtained from the in-house developmental toxicity studies with Sprague-Dawley Crl:CD (SD) rats performed in the period June 2001-April 2009.

Acceptability

The study is considered acceptable.

Conclusions

Based on the lack of adverse effects on mortality, clinical signs, body weight changes, food consumption, gross pathology and caesarean section data the highest dose level of 30 mg/kg bw/day was considered a NOAEL for maternal toxicity in this study.

a Study data obtained from Table 13 and historical control range from Attachment 4 in the Tables and Appendices section of the study report. Statistical analysis was conducted on all these observations.
Statistical analysis was conducted on the observations (Appendix M).
* Statistically different ($p \leq 0.05$) from the control.
** Statistically different ($p \leq 0.01$) from the control.

There were no treatment-related mortalities or clinical signs at any dose level tested.

In the high-dose group mean maternal body weight between GD 6 and 10 was lower than in controls ($p \leq 0.05$). Thereafter mean body weight gain was comparable to the controls throughout all intervals. Mean maternal corrected body weight change was reduced by 12% compared to the controls (not statistically significant) and slightly outside the range of in-house historical control data. Food consumption was transiently reduced by 20% between GD 6 and 8 ($p \leq 0.01$) and by 11% between GD 8 and 10 (not statistically significant). These effects on (corrected) body weight gain and food consumption were slight, and mainly transient.

At 15 and 7.5 mg/kg bw/day no treatment-related effects were observed on mean maternal body weights, body weight gains and maternal corrected body weight change. Mean maternal food consumption was similar to the controls.

There were no treatment-related macroscopic changes in the dams of any dose levels observed at necropsy. Mean liver weight was similar to the controls at all dose levels.

Pregnancy rate was similar in all groups. No treatment-related changes were noted on litter parameters, including the number of live fetuses, the number of implant sites per dam, the percentages of pre- and post-implantation losses, the number of early and late resorptions, the fetal death status, the fetal body weight and sex ratio.

There were no treatment-related malformations or variations noted at the fetal external examination. At 40 mg/kg/day, the incidence of the variation “eye bulge (uni/bi): protruding” was higher than in the control group and was outside the range of in-house HCD at the fetal level. However, as the observation was noted in only one litter and as the finding was not corroborated at the internal and skeletal observations, this increased incidence was considered to have occurred by chance.

There were no treatment-related malformations or variations noted at the fetal visceral and skeletal examinations. The observed skeletal variations (see Table 5.2) were not statistically different from the controls and were well within the in-house historical control data. Therefore they were not considered to be treatment-related.

Historical control data were generated from 14 developmental toxicity studies with New Zealand White Crl: KBL (NZW) rabbits performed by the testing laboratory in the period of March 2000 – October 2009.

Acceptability

The study is considered acceptable.

Conclusions

The effects on (corrected) body weight gain and food consumption were slight and mainly transient, however considered adverse (>10%) ~~and therefore considered not adverse~~.The NOAEL for maternal toxicity and developmental toxicity was set at 15 ~~40~~ mg/kg bw/day.

B.6.6.3 Summary

The results of the reproduction toxicity and teratogenicity studies are summarised in table 6.6.3-1.

Table 6.6.3-1 Summary of reproduction toxicity and teratogenicity studies

In the rangefinder one generation rat reproduction study, BYI 02960 was administered continuously in the feed to Wistar rats (10 animals/dose/sex) at nominal dietary concentrations of 0, 200, 700, and 2000 ppm. The parental systemic LOAEL is 700 ppm (60.0 mg/kg bw/day females), based on decreased body weight, decreased body weight gain, alterations in food consumption during premating, and decreased spleen weights in females. The parental systemic NOAEL is 200 ppm (17.5 mg/kg bw/day).
The reproductive NOAEL is 147.5 mg/kg bw/day based on no reproductive findings observed at the highest dose tested.
The offspring LOAEL is 700 ppm (60.9 mg/kg bw/day). The LOAEL is based on maternal effects leading to secondarily-mediated effects on pup weight, pup weight gain, and organ weight changes (brain). The offspring NOAEL is 200 ppm (17.5 mg/kg bw/day).

In the rat two-generation reproduction study, BYI 02960 was administered continuously in the diet to Wistar rats (30 animals/dose/sex) at nominal dietary concentrations of 0, 100, 500, and 1800 ppm. A significant decrease in body weight, but <10% was observed in the mid-dose of the F1 females and a non significant decrease in body weight gain was found in the parental animals (21 % in females) and the F1 animals (16 % in females). Therefore the parental systemic LOAEL is considered 500 ppm (32 mg/kg bw/d) based on decreased body weight gain in females. The parental systemic NOAEL is 100 ppm (6.4 ~~7.7~~ mg/kg bw/d). ~~Therefore the parental systemic LOAEL is considered 1800 ppm (117.4 mg BYI 02960/kg bw/day) based on increased liver and thyroid weights, and minimal centrilobular hypertrophy in males decreased body weight (>10%)(premating, gestation, and lactation), body weight~~

~~gain (premating; P and F_1). The parental systemic NOAEL was 500 ppm (32.0 mg BYI 02960/kg bw/day).~~ The reproductive NOAEL was 500 ppm (34.3 mg/kg bw/day females) based on decreased estrous cycle number, litter size, and the number of implants observed in the F_1 generation at the highest dietary level tested (1800 ppm =134.0 mg/kg bw/day in females). A significant decrease in body weight, but <10% was observed in the mid-dose of the F2 pups. The offspring LOAEL is therefore 1800 ppm (134.0 mg/kg bw/day) based on maternal effects leading to secondary effects on pup weight, and physical development. The offspring NOAEL is 500 ppm (34.3 mg/kg bw/day).

In a rat developmental study, BYI 02960 was administered daily by gavage to groups of 25 pregnant Sprague-Dawley female rats per dose-group at 0, 15, 50 and 150 mg/kg/day from gestation day (GD) 6 to 20. Minimal maternal toxicity was observed at the high-dose level, manifested as decreased body weight gain and reduced food consumption. The mean absolute liver weight was increased in the high dose group.Based on these findings the NOAEL for maternal toxicity was set at 50 mg/kg bw/day. The increased incidence of parietal incomplete ossification showed no dose response, the unossified cervical centrum and the incomplete ossification of the sternebra was within the historical background. A increase of a short costal cartilage was seen at the high-dose. Based on these findings, the NOAEL for developmental toxicity was set at 50 mg/kg bw/day.

In a complementary study, where groups of 23 sperm-positive female Sprague-Dawley rats were exposed to BYI 02960 by oral gavage from gestation day (GD) 6 to 20 at 0, 20 and 30 mg/kg/day, no maternal toxicity was observed up to 30 mg/kg/day. Therefore, based on these two studies, it can be concluded that the NOEL for maternal toxicity was 30 mg/kg/day.

In a rabbit developmental study, groups of 23 time-mated pregnant female New Zealand White rabbits were administered BYI 02960 by oral gavage from gestation day (GD) 6 to 28 at 0, 7.5, 15 and 40 mg/kg/day. The effects on (corrected) body weight gain and food consumption were slight and mainly transient, however considered adverse (>10%).The NOAEL for maternal toxicity and developmental toxicity was set at 15 mg/kg bw/day.~~There were no treatment-related findings for maternal and developmental toxicity therefore the NOAEL for maternal toxicity and developmental toxicity was set at 40 mg/kg bw/day.~~

B.6.7 NEUROTOXICITY / DELAYED NEUROTOXICITY (ANNEX IIA 5.7)

B.6.7.1 Acute oral neurotoxicity

STUDY 1

Characteristics

group size	:	Initial study: 12/sex/dose Follow-up study: 12 females/dose	**NOAEL**	:	35 mg/kg bw

Study design

The study was performed according to OECD 424. Initial study was performed with dose levels of 0, 50, 200 and 800 mg/kg bw with male and female rats (12/sex/dose). The follow-up study was performed in order to establish the NOAEL for the effects observed at all dose levels in the initial study, using the dose levels of 0, 20 and 35 mg/kg bw. Based on the higher sensitivity of females in the initial study, the follow-up study was performed with females only (12/dose). The animals in the follow-up study were sacrificed without necropsy.

Results

The results are summarised in Tables 6.7.1-1 (initial study) and 6.7.1-2 (follow-up study).

Initial study

During the initial study, one high-dose female died during neurobehavioral testing conducted at the time of peak effect after dosing. Another high-dose female was found dead on study day 5.

One week after dosing, mean absolute body weight gain was statistically significantly lower in high-dose animals of both sexes (-40% and -46% in males and females, respectively, compared to controls). Body weight gain recovered after day 7 and overall, was comparable to controls for the duration of the study.

In the high-dose animals, findings associated with treatment were observed at the time-of-peak effect (2 hours after dosing), including piloerection, lower muscle tone, rapid respiration, low arousal, tremors, myoclonic jerks, chewing, repetitive licking of lips, gait incoordination, flattened or hunched posture, dilated pupils, impaired (uncoordinated or slow) righting reflex, impaired flexor and tail pinch responses and reduced rectal temperature. Automated measures of motor activity were also reduced in both sexes, compared to controls.

In the mid-dose group, at the time-of-peak effect after dosing, treatment-related observations included piloerection, rapid respiration, gait incoordination and flattened body posture in both sexes, with a higher incidence of tremors in both sexes. In addition, automated measures of motor activity were reduced during the first 10-min interval of the session, while activity for the entire test session was comparable to controls.

At the low-dose level, the only treatment-related effects were limited to higher incidences of piloerection (both sexes) and dilated pupils (females only) at the time-of-peak effect after dosing.

All effects were reversible, with none observed at later time points of the study.

There were no macroscopic or microscopic treatment-related observations in either sex at any dose level.

Table 6.7.1-3: Summary of significant changes in open field observations during the initial study at time peak-effect

* : Statistically different (p ≤0.05) from the control

Follow-up study

No treatment-related effects were evident at either dose tested in the follow-up study that was performed to establish a NOAEL for effects observed at 50 mg/kg.

Acceptability

The study is considered acceptable.

Conclusions

Based on piloerection and dilated pupil in the initial study a LOAEL is 50 mg/kg. The NOAEL is therefore based on the follow-up study and set at 35 mg/kg bw in rats.

B.6.7.2 Semichronic oral neurotoxicity

STUDY 1

Characteristics

reference	:	[redacted]. 2011	exposure	:	Dietary 90 days
type of study	:	90-day Neurotoxicity study	doses	:	0, 5.7/6.9, 29.4/34.8, 143/173 mg/kg bw/d (M/F)
year of execution	:	2011	vehicle	:	None
test substance	:	BYI 02960 (batch number 2009-000239; purity 96.2%)	GLP statement	:	Yes

group size	:	12/sex/dose	**NOAEL sys** **NOAEL neuro**	:	29.4 mg/kbg bw/d 143 mg/kg bw/d

Study design

The study was performed according to OECD 424. The study was performed with dose levels of 0, 5.7/6.9, 29.4/34.8, 143/173 (M/F) mg/kg bw/d with male and female rats (12/sex/dose). Animals were observed for clinical signs daily, with body weight and food consumption measured weekly. A detailed

physical examination was performed once during the acclimatization phase and weekly throughout the study. Neurotoxicity assessment, consisting of a Functional Observational Battery (FOB) and automated measurement of motor activity, was performed on all animals on 5 occasions (pre-study, Study weeks 2, 4, 8 and 13 - 14). Ophthalmological examinations were performed on all animals during the acclimatization phase and on all animals of all dose groups during Week 13. All animals were subjected to a complete necropsy (macroscopic examinations). At least 6 animals from each group were perfused for neuropathological investigation. The brain was weighed and a range of tissues from the nervous system was collected, fixed and examined microscopically.

Results

Table 6.7.2-1 The results of the study

Motor activity measurements *- spontaneous motor activity*	No substance-related findings								
(Neuro-) Pathology *-Terminal body weight* *- brain to terminal body weight ratio* *- enlarged liver*							d	d is 4/6	
macroscopy	No treatment-related macroscopic findings were observed.								
microscopy	No treatment-related microscopic findings were observed.								

i/d: increased/decreased
is/ds: statistically significantly increased/decreased
dr: dose response

Up to and including the highest dose tested of 2500 ppm, there was no treatment-related mortality, clinical signs or ophthalmological changes during the study and no treatment-related effects were observed in any of the neurotoxicology endpoints, including neuropathological examinations, in either sex.

There were no treatment-related effects in either sex at 5.7/6.9 and 29.4/34.8 mg/kg bw/d.

At 143/173 mg/kg bw/d body weight parameters were clearly affected in both sexes, especially during the first week of treatment, when mean body weight remained static in females and the mean body

weight gain was 50% lower in males as compared to controls. Overall at the end of the study, mean body weight gain at this dose level represented 85% and 79% of the control values in males and females, respectively. Consequently, mean body weight remained lower compared to controls throughout the study in both sexes (- 7% to - 10% in males and - 5% to - 9% in females).
Mean food consumption was significantly lower in both sexes during the first week of treatment (- 18% and - 29% in males and females, respectively) and remained slightly lower in both sexes throughout the study (up to - 14% and up to - 13% in males and females, respectively, the effect being statistically significant on several occasions).
At necropsy, mean terminal body weight was 7% lower in both sexes, compared to controls. In remaining animals not used for neuropathology, enlarged liver was observed in 4/6 females.

Acceptability

The study is considered acceptable.

Conclusions

Body weight and food intake effects were seen at the highest dosage. The systemic NOAEL is therefore 29.4/34.8 mg/kg bw/d for males and females respectively.
There was no evidence of neurotoxicity at dietary levels as high as 143 mg/kg bw/d (males), therefore this is considered to be a NOAEL for neurotoxicology.

B.6.7.3 Developmental neurotoxicity

Study 1

Characteristics

reference	:	[redacted].; 2012	exposure	:	Dietary, GD 6 -LD 21
type of study	:	A Developmental Neurotoxicity Study	doses	:	0, 120, 500 and 1200 ppm
year of execution	:	2012	vehicle	:	none
test substance	:	BYI 02960 (batch number 2009-000239; purity 96.2%)	GLP statement	:	Yes
route	:	Oral	guideline	:	According to OECD 426
species	:	Rat, Wistar Rj:WI (IOPS HAN)	acceptability	:	Acceptable
group size	:	30 females/dose	**NOAEL maternal**	:	500 ppm (42.4 mg/kg bw/d)
			NOAEL developmental		500 ppm (42.4 mg/kg bw/d)
			NOAEL developmental neurotoxicity		500 ppm (42.4 mg/kg bw/d)

Study design

The study was performed according to OECD 426. BYI 02960 was administered via the diet from gestation Day (GD) 6 through lactation Day (LD) 21 to mated female Wistar rats at nominal concentrations of 0, 120, 500, or 1200 ppm with adjustment during lactation to maintain a more consistent dosage throughout the period of exposure. The average mean daily intake of the test substance (mg BYI 02960/kg bw/day) based on the average dietary consumption for the last two weeks of gestation and three weeks of lactation at 120, 500, or 1200 ppm, respectively, was 0, 10.3, 42.4, and 102 mg/kg bw/day. All test diets (including control) were provided for ad libitum

consumption throughout the study, except during neurobehavioral testing. The Parental (P)-generation females were evaluated by cage-side and detailed clinical observations, body weight, food consumption, and reproductive endpoints. On postnatal Day (PND) 4, litters with a minimum of seven pups, including at least three per sex, were culled to yield, as closely as possible, four males and four females. Subsets of surviving offspring, representing 19–20 litters per dietary level, were subjected to evaluation using the following observations and measurements: detailed clinical observations and a detailed observational battery, pupil response, surface righting, balanopreputial separation or vaginal patency, body weight, food consumption, automated measures of activity (figure-eight maze), auditory startle habituation, learning and memory (passive avoidance after weaning and a water maze task beginning on PND 60 ± 2 days), and an ophthalmic examination. Neural tissues were collected from 10 rats/sex/dietary level (representing 20 litters) on PND 21 (brain only) and at study termination (approximately 75 days of age) for microscopic examination and morphometry.

Results

The results are summarised in Tables 6.7.3-1 (parental animals) and 6.7.3-2 (offspring).

Parental animals

[a] Number of animals assigned to each dietary level.
[b] Values are mean ± S.E., [median], and (range).
Values were not statistically different from control, $p \leq 0.05$ or $p \leq 0.01$

During gestation, findings considered incidental and unrelated to the test substance included red vaginal discharge on GD 13 (1 mid-dose dam), fused digits (1 control dam), and hair loss (1 to 3 dams from all dietary levels, including controls), which is a common finding associated with nest-building

behavior in pregnant rats. During lactation, findings that are considered incidental and unrelated to the test substance included fused digits (1 control dam) and areas of hair loss (1 to 4 dams at all dietary levels, including control).

During gestation, there was a statistical decrease (-7%), relative to controls, in mean body weight on GD 20 and a statistical decrease (-21%) in overall mean weight gain during gestation (GD 0-20) at the 1200 ppm dietary level. There were statistical decreases in body weights on LD 0 and 4 (-4% and -6%, respectively), relative to controls, at the 1200 ppm dietary level, and non-statistical decreases (-4% to -6%) that continued through termination on LD 21 at the 1200 ppm dietary level. There were no effects on body weight or body weight gain during gestation or lactation at any other dietary level.

Offspring

Values are mean ± S.D. *** Statistically different from control, ANOVA $p \leq 0.05$.

Body weight was non-statistically decreased in high-dose males and females on PND 17 and 21 (-4% to -5%). Although these differences from control are small and not statistically significant, they are attributed to the test substance because of the relationship with dose (both genders and at multiple time points). These lower body weights were comparable to the 4–6% lower body weight for the high-dose dams throughout lactation. Body weight was not affected by the test substance in either sex at any other dietary levels. Body weight gain for PND 4–17 was statistically decreased in high-dose males (-7%). Body weight gain for the shorter period of PND 11–17 was statistically decreased in high-dose males (-10%), females (-7%). There were similar non-statistical trends in body weight gain for PND 4–17 in high-dose females (-6%), for PND 4–21 and PND 11–21 in both sexes. These differences from control are attributed to the test substance. Body weight gain was not affected by the test substance in either sex at the 120 and 500 ppm dietary levels. There was no difference in body weight after weaning for males and females at any dietary level.

A non-statistical increase in both motor and locomotor activity was measured in high-dose males on PND 13. These differences from control are considered test substance-related, but are also partially attributed to a low mean average activity for controls (55 and 5, for motor and locomotor, respectively), which was below the range for historical controls (59–72 and 6–11, respectively) in the last five studies conducted at this laboratory. An increase in motor activity was measured in low- and high-dose males on PND 17. These differences from control are not attributed to the test substance, since there was no dose-related pattern and the increases were not observed in mid-dose males or in females. Additionally, the increases were not observed on any subsequent test occasions, and means for all groups were within the range of historical controls. An increase in locomotor activity was measured in low-, mid-, and high-dose males on PND 17. These differences from control are not attributed to the test substance, since there was no dose-related trend, increases were not observed in females and the means were within the range of historical controls. Lastly, very slight increases in locomotor activity were measured in low-dose males on PND 21 and high-dose females on PND 60. These are

not considered test substance-related since motor activity for these same animals was generally comparable to controls, other dose levels were not similarly affected, and the differences were seen in only one sex.

In the auditory startle habituation test startle amplitude for all 50 trials was statistically increased two-fold in high-dose females (156 g), compared to controls (78 g) on PND 60. This was reflected as a non-statistical increase in response amplitude for the first block of trials, and a statistical increase in blocks 2–5, relative to control. This finding is considered to be related to the test substance. There was a non-statistical trend involving a slight increase in average startle amplitude in all five blocks of trials, in females at the low- and mid-dose, relative to controls, on PND 60. This difference from control is not thought to be test substance-related since the slight increase was similar in both dose levels with a 4-fold increase in dose and the mean average for startle response amplitude in control animals (78 g) is below the range for historical controls (87–116 g) in the last five studies conducted in this laboratory. There were no differences in startle amplitude in male and female weanlings or in adult males at any dietary level age. Startle latency and habituation were not affected by the test substance in males or females at any dietary level, on any test occasion.

Test substance-related mean terminal body weight changes for PND 21 pups were noted in males at 1200 ppm dietary level (non-statistically decreased, 8%, as compared to controls) and in females at 120, 500, and 1200 ppm dietary levels (non-statistically decreased, -5, -7%, and -8%, respectively, as compared to controls).
Terminal body weights are collected once at termination from a sub-group of animals in each dose level (i.e., those animals scheduled for necropsy; 10/sex/dietary level). In-life body weights are collected from all animals at selected time points throughout the in-life phase of the study (e.g., mean litter weight is calculated using 23 litters/level). Although the sub-group of animals weighed at termination did indicate an apparent effect on body weight, in-life data clearly indicates no effect on body weight (compared to controls) in females from the 120 and 500 ppm dietary levels.
There was no test substance-related terminal body weight change noted at any dietary level in the PND 75 (± 5 days) perfused rats.
There was a slight trend of decline in terminal body weights at 1200 ppm males (-5%, as compared to controls) in the PND 75 (± 5 days) non-perfused rats. There was a decrease (-5%) in terminal body weights observed in 120 and 1200 ppm females; however, these changes were not considered test substance-related due to lack of dietary relationship or the changes were small.

There was a decrease (-5%) in fresh brain weights at 1200 ppm males as compared to controls in the PND 75 (± 5 days) Rat**,** however, this change was not considered directly related to test substance administration since it was related to the decrease in terminal body weights.
The brain weight range for the non-perfused males was 1.769 g to 2.050 g and the range for the non-perfused 1200 ppm treated males was 1.739 g to 1.993 g with only two animals with a brain weight outside the control range.

Acceptability

The study is considered acceptable.

Conclusions

Dietary exposure to BYI 02960 from GD 6 through LD 21 to mated female Wistar rats resulted in treatment-related effects (maternal: decreased body weight gain. Offspring: decreased body weight gain, slightly increased in motor and locomotor activity, slightly increased auditory startle habituation) evident only at 1200 ppm (102 mg/kg bw/day) in maternal animals and offspring. ~~Therefore, the NOAEL for both maternal animals and offspring is 500 ppm (42.4 mg/kg bw/day) in this developmental neurotoxicity study.~~

The maternal NOAEL was 500 ppm (42.4 mg/kg bw/d) based on decreased body weight and body weight gain. The developmental NOAEL was 500 ppm (42.4 mg/kg bw/d) based on decreased offspring body weight and body weight gain. The developmental neurotoxicity NOAEL was 500 ppm (42.4 mg/kg bw/d) based on increased startle amplitude in females only on PND 60 and increased motor and locomotor activity on PND 13 in males only.

B.6.7.4 Summary

The results of the neurotoxicity studies are summarised in table 6.6.3-1.

Table 6.6.3-1 Summary of neurotoxicity studies

Type of study	Species	NOAEL (mg/kg bw/d)	LOAEL (mg/kg bw/d)	Critical effects	Reference
Acute neurotoxicity in the rat	Rat	35	50	Piloerection, dilated pupil	[redacted], 2011
90-day neurotoxicity in the rat	Rat	29.4 (systemic) 143 (neuro)	143 -	Reduced body weight and food intake. None	[redacted], 2011
Developmental neurotoxicity in the rat	Rat	42.4 (maternal) 42.4 (developmental) 42.4 (developmental neurotoxicity)	102 102 102	Maternal: decreased body weight gain Offspring: decreased body weight gain Develompental neurotoxicity: slightly increased motor/locomotor activity and startle habituation.	[redacted]; 2012

In an acute neurotoxicity study, BYI 02960 was administered by gavage in a single dose to non-fasted young adult Wistar rats at 0, 50, 200 and 800 mg/kg bw. Compound-related effects were observed at all dose concentrations in both sexes. The only treatment-related effects at 50 mg/kg were limited to higher incidences of piloerection in both sexes and dilated pupils in females only. A follow-up study was performed in order to establish a clear NOAEL for findings observed at all dose levels in the initial

study. In this follow-up study, females only were used as they were equal or more sensitive than males at higher dose levels and were administered BYI 02960 at 0, 20 or 35 mg/kg. No treatment-related effects were evident at either dose tested. The dose level of 35 mg/kg of BYI 02960 was considered to be the overall NOAEL for both sexes.

In a 90-day neurotoxicity study, through approximately 13 weeks of continuous dietary exposure to BYI 02960 at 0, 100, 500 or 2500 ppm, there were no neurotoxic treatment-related findings apparent at any dietary level in either sex. Based on these findings, a NOAEL of 2500 ppm was established for the rat (equating to 143 mg/kg bw/day for males). Body weight and food intake effects were seen at the highest dosage. The systemic NOAEL is therefore 29.4/34.8 mg/kg bw/d for males and females respectively.

In a developmental neurotoxicity study, dietary exposure to BYI 02960 from GD 6 through LD 21 to mated female Wistar rats resulted in treatment-related effects (maternal: decreased body weight gain. Offspring: decreased body weight gain, slightly increased in motor and locomotor activity, slightly increased auditory startle habituation) evident only at 1200 ppm (102 mg/kg bw/day) in maternal animals and offspring. ~~Therefore, the NOAEL for both maternal animals and offspring is 500 ppm (42.4 mg/kg bw/day) in this developmental neurotoxicity study.~~

The maternal NOAEL was 500 ppm (42.4 mg/kg bw/d) based on decreased body weight and body weight gain. The developmental NOAEL was 500 ppm (42.4 mg/kg bw/d) based on decreased offspring body weight and body weight gain. The developmental neurotoxicity NOAEL was 500 ppm (42.4 mg/kg bw/d) based on increased startle amplitude in females only on PND 60 and increased motor and locomotor activity on PND 13 in males only.

B.6.8 OTHER TOXICOLOGICAL STUDIES (ANNEX IIA 5.8)

Literature search

With respect to Article 8(5) of Regulation (EC) No 1107/2009 a literature search has been conducted for flupyradifurone and its metabolites.

The following list gives an overview of all bibliographic databases searched. The time frame that was considered ranged from January 1, 2012 until April 23, 2011. As requested in the EFSA Guidance Document, all scientific peer-reviewed open literature has been considered and downloaded. Publications related to patents were not considered in the literature search.

Bayer CropScience has searched what it considers a broad collection of relevant databases (see list below). STN was selected as the preferred provider, because it offers a convenient search service that includes all databases considered relevant to cover the requirements established under Article 8(5) of Regulation (EC) 1107/2009.

The databases used in the literature search of flupyradifurone were:

Agricola	Biosis	CABA	Chemical Abstracts
Derwent Crop Protection (CROPU)		Derwent Drug File (DRUGB, DRUGU)	
EMBAL/ EMBASE	Esbiobase	IPA	Lifesci
Medline	Pascal	Registry	Scisearch
Toxcenter	Ulidat	FSTA	

The data that was used as input parameter for the database search included: active substance and its metabolites, including report name, structure, IUPAC name, CAS name/number, molecular formula, molar mass and other names/codes, as far as available. The categories/keywords which were used as text mining filter is very extensive and therefore not reported in the DAR.
All references were reviewed by the scientific experts, categorised according to the corresponding OECD dossier sections – if possible- and evaluated for their relevance.

A total of 342 publications were found for flupyradifurone and its metabolites. When using the keyword list as a text mining filter, 136 references were identified, 206 references were not related to any of the keywords. From those references which could not be assigned to any of the categories "health", "environment" or "non target species", none was identified by the scientific experts to provide relevant information for regulatory purposes, *i.e.* no false negative findings were identified. This indicates that the text mining filter may be considered as an appropriate tool for a first step of future literature reviews.

No unknown reference turned out to be relevant according to the definition under which this literature review has been carried out ("dealing with side-effects on health, the environment and non-target species"). No information was identified that was considered to have an impact on an endpoint or would result in the need to adapt a risk assessment in the flupyradifurone dossier .

Since no unknown publication turned out as relevant, Bayer CropScience does not consider it necessary to have a separate discussion of individual publications in appropriate Annex points of the dossier. Instead, we think it is sufficient to list all references that have become available as a part of this literature report (see Appendix C).

Even though the filter identified a large number of references as potentially relevant by comparing keywords in the list with the title and abstract of the publication, in the area of toxicology only one, but already known reference eventually was considered by Bayer CropScience development experts as relevant under the definition of criteria for relevance with respect to Article 8(5) of Regulation (EC) No 1107/2009.

Remarks RMS

A literature search and review was provided by the applicant. The search has been conducted in line with the EFSA guidance. Of all identified papers (342) the relevant ones (136) have been selected by the applicant in a transparent way using a text mining filter. The applicant provided a general justification for evaluating the relevant papers. As no study-by-study justifications were given the RMS can not properly verify whether the 136 relevant papers were correctly evaluated in terms of reliability/validity/acceptability for regulatory use. The one study that was considered relevant by the applicant is evaluated in the DAR. RMS notes that flupyradifurone is a new active substance worldwide. Therefore, public literature is not expected to be an important new information source for the active substance itself.

B.6.8.1 Biokinetic study

The biokinetic study below is performed to assess if the Cmax concentration of flupyradifurone can be determined in a certain period.

Study 1

Characteristics

Reference	:	[redacted]., 2010	exposure	:	diet 7-days
type of study	:	Biokinetic in the plasma of rats following 7 day exposure through the diet	dose	:	400 ppm (equivalent to app. 22.6 mg/kg bw/d in males and 32.4 mg/kg bw/d in females)
year of execution	:	2009-2010	vehicle	:	- (dry mixing with the diet)
test substance	:	flupyradifurone (Batch 2009-000239, purity 96.2%)	GLP statement	:	Not GLP but in a GLP laboratory
Route	:	Oral	guideline	:	-
Species	:	Rat Rj: WI (IOPS HAN)	acceptability	:	Acceptable as indicative study
group size	:	5 male, 5 female	**NOAEL**	:	-

Study design

The plasma concentration of flupyradifurone was assessed at three time points after continuous dietary administration for seven days. Groups of 5 male and 5 female Wistar rats received the diet admixed with the test substance at a concentration of 400 ppm (equating approximately to 22.6 mg/kg body weight/day in males and 32.4 mg/kg body weight/day in females).

During the first 15 days of acclimatization, the daily light/dark rhythm was 7 a.m. - 7 p.m. Rats being known to preferably eat during the dark period, the daily light/dark rhythm of rats was changed from pre-study Day 16, *i.e.* 14 days prior to first day of treatment, onwards, *i.e.* dark period was from 2 a.m. to 2 p.m. and light period was from 2 p.m. to 2 a.m., in order to allow the blood sampling during the working day. Clinical signs were observed daily. Body weights were measured just prior to the start of admixed food administration (Study Day 1) and on Study Day 8. Food consumption was recorded on Study Days 1 - 4, 4 - 7 and 7 - 8.

Whole blood was collected on heparin for plasma preparation from treated animals at three time points on Study Day 8, 6 hours after the start of feeding (8 am), 12 hours (2 pm) and 15 hours (5 pm). As the compound is rapidly absorbed, this should correspond to the period where the blood concentration in BYI 02960 should be higher. Blood samples collected at later time points should be lower. This should provide enough information to know when blood samples should be collected during subchronic or long term studies.The day after the end of the treatment period, animals were sacrificed without necropsy.

Results

There were no mortalities and no treatment-related clinical signs observed during the study. The few clinical signs observed (hair loss observed on two females) were considered not to be related to

flupyradifurone administration. Body weight evolution and food consumption were similar to the one observed in the other repeated dose studies.

The individual and mean concentrations of flupyradifurone in plasma samples were used to identify the appropriate maximal concentration (Cmax) and the corresponding time point of collection for the long-term studies.
The results obtained indicated a small sex difference in the plasma concentrations of flupyradifurone, values being slightly higher for females than for males.
In male rats, a Cmax of 8.3 mg/L was measured at the time of collection of 8 a.m. In female rats, a Cmax of 9.4 mg/L was measured at the time collection of 2 p.m. However, in view of the inter-individual variability, the concentrations of flupyradifurone in plasma were considered similar between the three times of blood collection for both sexes (between 7.8 and 8.3 mg/L for males and between 8.8 and 9.4 mg/L for females).

TT1F4989		7.91		
TT1F4990		11.2		
TT1F4991		7.67		

Using the experimental study design, blood samples collected between 8 a.m. and 5 p.m. are adequate for measuring flupyradifurone concentrations in plasma around the C_{max} for both sexes.

Acceptability

The study is not performed in GLP compliance. It was performed according to standard operation procedures of the GLP compliant laboratory but the results were not subjected to specific quality assurance inspections. The study is considered acceptable as supplementary study.

Conclusions

In conclusion, in the environmental conditions of the long-term studies (light: 7 a.m. to 7 p.m. & dark period: 7 p.m. to 7 a.m.) and since animals start eating food when the light is switched off, the blood collection can be performed between 1 a.m. and 10 a.m. in order to measure the maximum concentration of flupyradifurone in the ADME studies.

B.6.8.2 Immunotoxicity

Study 1

Characteristics

bw/d

Study design

This study was conducted according to U.S. E.P.A., OPPTS Series 870, Health Effects Testing Guidelines N° 870.7800 (August 1998). Female Wistar rats (10/group) were administered flupyradifurone continuously via dietary administration for at least 28 days at concentrations of 0, 125, 600 and 3000 ppm (equivalent to approximately 0, 10, 50 and 230 mg/kg bw/d). A similarly constituted group received untreated diet and a similarly constituted group received the positive control 3.5 mg/kg bw/d cyclophosphamide (immunosuppressive agent) for at least 28 days.

All animals were immunized with Sheeps Red Blood Cell (SRBC) antigen by intravenous injection of 2.5 x 10^8 SRBC/animal via the tail vain.

Mortality and clinical signs were observed daily, food consumption and body weight were recorded once weekly. Blood samples were collected of each surviving animal on study day 30 (just before necropsy) for specific anti-SRBC immunoglobulin M (IgM) analysis. All animals were necropsied, gross pathology observations were performed and spleen and thymus weighed.

Results

The flupyradifurone was homogeneous distributed through the diet and the concentrations were acceptable in the diet, in addition the formulation at 3000 ppm was found stable up to 34 days at room temperature in rodent diet.

One animal showed automutilation of both forelimbs and was killed for humane reasons.

Table 6.8.2-1

Dose (mg/kg bw/d)	**0**	**10**	**50**	**230**

Day 8				**d**
Day 15				**d**
Day 22				**d**
Day 29				**d**
Gross Pathology				
macroscopy	No macroscopic finding was noticed.			
Mean spleen weight	No substance-related findings			
Mean thymus weight				
Clinical pathology				
SRBC-specific Ig-M	No substance-related findings			

CPP = cyclophosphamide (positive control)
ds/is statistically significantly decreased/increased compared to the controls
d/i decreased/increased, but not statistically significantly compared to the controls

Mean body weight at 3000 ppm was reduced by 6 to 11% from Study Day 8 to 29 when compared to the control group. The effect was statistically significant on the intervals Day 1 to 8 and Day 8 to 15. There was no body weight gain/day between Study Day 1 and 8. Body weight gain was then similar to control animals at the following intervals. Between Study Day 1 and 29, the cumulative body weight was reduced by 23%, when compared to the control group.
At 600 and 125 ppm, body weight parameters were unaffected by treatment.

At 3000 ppm, mean food consumption was reduced by approximately 34% on Study Day 8 and by 9 to 13% onwards, when compared to control group although not statistically significant.
At 600 and 125 ppm, food consumption wasunaffected by treatment.

The spleen and thymus weight changes were considered to be incidental and not treatment-related (no dose response in the organ to bw ratio).

Table 6.8.2-2: Mean organ weights and organ/terminal body weight ratios.

Mean organ weight ±SD at scheduled sacrifice (% change when compared to controls)				
Sex	**Female**			
Dose level mg/kg bw/d	**0**	**10**	**50**	**230**
Mean absolute spleen weight (g)	0.762 ±0.122	0.743 ± 0.110	0.732 ± 0.135	0.720 ± 0.096
Mean spleen to body weight ratio (%)	0.316 ± 0.038	0.312 ±0.037	0.301 ± 0.039	0.319 ±0.036
Mean absolute thymus weight (g)	0.544 ±0.130	0.505 ± 0.075	0.591 ±0.154	0.522 ± 0.104
Mean thymus to body weight ratio (%)	0.226 ±0.048	0.212 ± 0.033	0.242 ± 0.053	0.230 ± 0.036

No statistically significant difference was noted in anti-SRBC IgM concentrations up to 3000 ppm. A high inter-individual variability was noted in all the groups as usually observed with SRBC sensitization. No dose-effect relationship was seen, the variations observed were due to only few animals.

Table 6.8.2-3: Mean SRBC-specific IgM

SRBC-specific IgM (u/mL) mean ± standard deviation (% change when compared to controls)				
Dose level mg/kg bw/d	**0**	**10**	**50**	**230**
Study Day 30	**40516 ± 23875**	**62920 ± 41649 (+ 55%)**	**34286 ± 30710 (- 15%)**	**33354 ± 26016 (- 18%)**

In the positive controls (cyclophosphamide at a dose level of 3.5 mg/kg/day) there was no change in mean terminal body weight in treated animals when compared to the controls. The principal findings noted at the macroscopic examination were atrophic/small spleen and/or thymus (6/10 and 5/10

respectively) which correlated with significantly lower mean absolute and relative spleen and thymus weights (- 34% to - 32% and - 28% to - 27% respectively).

Table 6.8.2-4: Mean spleen weights

Mean spleen weight ±SD at scheduled sacrifice (% change when compared to controls)		
Sex	**Female**	
Dose level of Cyclophosphamide (mg/kg/day)	0	3.5
Mean absolute spleen weight (g)	0.762 ± 0.122	0.500** ± 0.049 (- 34%)
Mean spleen to body weight ratio (%)	0.3161 ± 0.0380	0.2136** ± 0.0176 (- 32%)

** : p ≤0.01

Table 6.8.2-5: Mean thymus weights

Mean thymus weight ±SD at scheduled sacrifice (% change when compared to controls)		
Sex	**Females**	
Dose level of Cyclophosphamide (mg/kg/day)	0	3.5
Mean absolute thymus weight (g)	0.544 ± 0.130	0.389** ± 0.063 (- 28%)
Mean thymus to body weight ratio (%)	0.2259 ± 0.0482	0.1656** ± 0.0202 (- 27%)

** : p ≤0.01

In the positive controls the mean anti-SRBC IgM concentration was markedly lower when compared to controls (- 93%).

Table 6.8.2-6: Mean SRBC-specific IgM

SRBC-specific IgM (u/mL) mean ± standard deviation (% change when compared to controls)		
Dose level of Cyclophosphamide (mg/kg/day)	0	3.5
Study Day 30	**40516 ± 23875**	**2732 ± 1737** **(- 93%)**

Acceptability

The study is considered acceptable.

Conclusions

The mean body weight and mean food consumption was reduced at 3000 ppm (230 mg/kg bw/d). For the immunological response, no relevant change was noted in anti-SRBC IgM concentrations up to 3000 ppm (230 mg/kg bw/d) and no significant change was noted in the spleen and thymus weight. The systemic flupyradifurone NOAEL is 600 ppm (equivalent to approximately 50 mg/kg bw/d), and the immunotoxic NOAEL is >3000 ppm (equivalent to approximately 230 mg/kg bw/d).

B.6.9 STUDIES ON METABOLITES

The toxicological properties of two metabolites specific to BYI 02960 and two additional metabolites which are also formed from other agrochemicals are reported in this section.

Difluoroacetic acid (DFA, BCS-AA56716, M44) is a major soil, water, plant and livestock metabolite of BYI 02960. In the rat ADME study, it was found in urine at around 6% of the administered dose and the organ metabolism study showed that DFA was by far the dominating metabolite in the 24 hours samples of plasma, organs and tissues, accounting for more than 50% of the radioactivity

BYI 02960-difluoroethyl-amino-furanone (BCS-CC98193, BYI 02960-DFEAF, M34) is a minor plant metabolite of BYI 02960 and was also observed in the rat ADME study. It accounted for less than 10% of the administered dose in the rat urine. Since the confined rotational crop study with [furanone-4-^{14}C]BYI 02960 indicated rather high residue levels of BYI 02960-difluoroethyl-amino-furanone in leafy crops and the absence of other suitable markers, this metabolite is included in the residue definition for the data collection method for target and rotational crops (see residue section).

BYI 02960-CHMP (6-chloropyridin-3-ylmethanol, IM-O, M21) and **BYI 02960-6-CNA (6-chloronicotinic acid, IC-0, M27)** are metabolites common to other pesticides. In rat BYI 02960-CHMP was not found and BYI 02960-6-CNA was found up to 6% of the applied dose. Both metabolites are plant metabolites whereas BYI 02960-6-CNA is also found in soil.

Expert consultation 2.9

For the metabolite DFA:

The decreased glucose concentration was the only treatment-related effect at all doses in the **14-day study**. In the absence of other findings, the RMS considered this change as not adverse and proposed a NOAEL of 500 ppm based on effects on body weight (-12% in females). Bilirubin decrease (in females only) and increased urea were observed in all dose groups without dose response relationship or concurrent findings in organs. The experts agreed on a NOAEL of 500 ppm corresponding to 51 mg/kg bw per day.

In the **90-day study**, bilirubin and glucose effects were observed in all dose groups. No dose-response relationship was observed in the clinical chemistry parameters. The RMS proposed a

NOAEL of 200 ppm corresponding to 12.7 mg/kg bw per day based on reduced body weight gain. This was agreed by the experts.

In the rat metabolism, DFA did not appear as a major metabolite.

Comparison with the toxicity profile of the parent could not be concluded.

The experts considered the use of the reference value of the parent or reference values derived from specific data with the metabolite. The majority agreed to use the reference values of the parent.

For the metabolite BYI 02960-difluoroethyl-amino-furanone:

In the **14-day rat** dietary study, the proposed NOAEL is 1280 ppm corresponding to 135 mg/kg bw per day based on reduced bw gain and lower blood glucose concentration in females.

In the **28-day rat** dietary study, the proposed NOAEL is 3000 ppm corresponding to 243 mg/kg bw per day.

The experts agreed with the RMS conclusions.

Historical control data were provided for the positive *in vitro* chromosome aberration test; negative results were obtained in a micronucleus test where exposure of the bone marrow was indirectly demonstrated by signs of general toxicity. In the absence of toxicokinetic data for the metabolite, this might not be considered as a direct sign of exposure of the bone marrow. An *in vivo* UDS test provided also negative results but might not be the most appropriate follow up (nowadays a Comet assay would be required).

In the ADME studies of the parent, this metabolite has been found in urine, plasma, kidney, muscle.

The experts agreed that negative results in micronucleus and UDS tests *in vivo* were sufficient to conclude on the absence of genotoxic potential for this metabolite.

The RMS proposed that the reference values of the parent should be applied to this metabolite as well. This approach was agreed by the experts.

B.6.9.1 Difluoroacetic acid (DFA, BCS-AA56716, M44)

B.6.9.1.1 Acute toxicity Difluoroacetic acid (DFA, BCS-AA56716, M44)

Study 1

Characteristics

reference	:	[redacted]. 2010	exposure	:	Once by gavage
type of study	:	Acute oral toxicity study	doses	:	300, 2000 mg/kg bw
year of execution	:	2009	vehicle	:	Purified water
test substance	:	BCS-AA56716 (batch BCOO 5984-4-11, purity 96,7%)	GLP statement	:	Yes
route	:	Oral	guideline	:	According to OECD 423

species	:	Nulliparous and non-pregnant female rats Sprague-Dawley Rj: SD (IOPS Han)	acceptability	:	Acceptable
group size	:	3f/dose	**LD50-cut off**	:	Between 300-2000 mg/kg bw

Study design

The study was performed in accordance with OECD 423.

Three groups of three female rats Sprague-Dawley were given a single oral dose (10 mg/lkg) of BCS-AA56716 (batch BCOO 5984-4-11, purity 96.7%). The substance was tested using a stepwise procedure, each step using three female rats. The animals were assigned to their groups by randomization based on evenly distributed chance numbers. Following an overnight fast (18 hours), the first group received a single dose of 300 mg/kg of BCS-AA56716 (96.7% purity) by gavage. The test substance was administered in purified water at a volume of 10 mL/kg bw. After the first assay, as no deaths occurred, another assay was carried out on three animals at the next higher dose-level (2000 mg/kg). After the second assay, as 2/3 animals died, the results were confirmed in three other females at the dose-level of 300 mg/kg. Clinical signs and mortality rates were determined several times on the day of administration and subsequently at least once daily for an observation period of at least 14 days. Body weights were recorded on days 1, 8 and 15. On day 15, surviving animals were sacrificed and all animals were necropsied and examined for gross pathological changes.

Results

Table 6.9.1.1-1 Mortality:

Dose mg/kg bw	Mortality	Time of death
1st 300	0/3	--
2nd 2000	2 ~~1~~/3	1h
3rd 300	0/3	--

Symptoms of toxicity:

At the 2000 mg/kg dose-level (three females), two females were found dead 1 hour after treatment. Hypoactivity, dyspnea and/or lateral recumbency were observed within 25 minutes prior to their deaths. In the surviving animal at 2000 mg/kg, sedation then hypoactivity, dyspnea, lateral recumbency, piloerection and staggering gait were noted from day 1 until day 9. At 300 mg/kg, loud breathing was recorded in 1/6 females on day 3. No other clinical signs were noted.

Body weight:

When compared to CIT historical control data, a lower body weight gain (28 g *vs.* 41 ± 9 g in control data base) was noted in 1/6 females given 300 mg/kg between day 1 and day 8. The body weight gain of this female returned to normal thereafter. The body weight gain of the other animals was not affected by the test item-treatment.

A body weight loss of 8% (185 g *vs.* 201 g) was noted in the surviving female given 2000 mg/kg, between day 1 and day 8. The body weight gain of this female return to normal thereafter.

Necropsy:

No abnormalities were observed at gross necropsy.

Acceptability

This study is considered acceptable.

Conclusions

The LD50-cut off of BCS-AA56716 was found to be between 300-2000 mg/kg bw.

B.6.9.1.2 Genotoxicity Difluoroacetic acid (DFA, BCS-AA56716, M44)

Study 1

Study design and results

Pos. control	408	1730	1684	2007	1956	2739	1631	367	79	230

No substantial increase in revertant colony numbers of any of the five tester strains was observed following treatment at any concentration level, neither in the presence nor absence of metabolic activation.

Acceptability

The study is considered acceptable.

Conclusions

BCS-AA56716 is not mutagenic in the Ames test.

<u>Study 2</u>

						harvest at the same time)	

a The guideline requires three analysable concentrations, in this study the concentrations of 240.0, 480.0 and 960.0 µg/mL were selected.

Test substance: BCS-AA56716 (batch number BCOO 5984-4-11; batch code: BCS-AA56716-01-02; purity 96.7%); tested in DMSO
Precipitation: No precipitation of the test substance was observed.
Toxicity: No relevant cytotoxic effects indicated by reduced mitotic indices or reduced ceil numbers to approximately 50% were observed after treatment with the test substance. The highest tested concentration (960.0 µg/mL) was equal to a molar concentration of about 10 mM.
GLP statement: yes
According to OECD 473: yes
Adequate positive and negative controls were included.

a Inclusive cells carrying exchanges;
b Evaluation of 200 metaphases per culture due to inhomogeneous data;
c Evaluation of 50 metaphases per culture due to strong clastogenic effects;
d Aberration frequency statistically significant higher than corresponding control values.

In both experiments, in the absence and presence of S9 mix, no biologically relevant increase in the number of cells carrying structural chromosome aberrations was observed. In experiment I in the absence of S9 mix an isolated single increase in the number of aberrant cells, excluding gaps (4.5%) slightly exceeding the total laboratory's historical solvent control data range (0.0 - 4.0% aberrant cells, excluding gaps) was observed after treatment with 480.0 µg/mL This observation was regarded as biologically irrelevant, since the value was not statistically significantly increased and no increase was observed at the highest applied dose of 960 µg/mL.
No relevant evidence of an increase in polyploid metaphases was noticed after treatment with the test item as compared to the controls (information provided only as text, no table with results regarding polyploid metaphases was shown in the report).

Acceptability

The study is considered acceptable.

Conclusions

BCS-AA56716 did not induce structural chromosome aberrations in V79 cells when tested up to and including cytotoxic concentrations. Furthermore, no relevant evidence of an increase in polyploid metaphases was noticed after treatment with the test substance as compared to the controls.

<u>Study 3</u>

Study design and results

Type of study: mammalian cells in vitro, gene mutation test

Indicator cells	Endpoint	Res. –act.	Res. +act.	Activation		Dose range	Reference
				Tissue	Inducer

Table 6.9.1.2-5 Gene mutation in mammalian cells - 2nd experiment

Treatment group	Relative cloning efficiency Ia	Relative cell density	Relative cloning efficiency IIb	Mutant colonies / 106 cells	Induction factor
Positive control DMBA					
1.1 µg/mL	21.2	37.2	58.2	1185.9	43.9

a cloning efficiency determined immediately after treatment to measure toxicity;
b cloning efficiency determined after the expression period to measure viability of the cells without selective agent.
n.c.: culture was not continued since a minimum of only four analysable concentrations is required.
n.c.c.: culture not continued due to contamination.

No relevant and reproducible increase in mutant colony numbers/106 cells was observed in the main experiments up to the maximum concentration. The induction factor exceeded the threshold of three times the corresponding solvent control in the first culture of the first experiment without metabolic activation in all dose groups. This effect however, was judged to be due to the rather low solvent controls of 5.8 mutant colonies/106 cells. The induction factor was well below 3.0 in the respective parallel culture. Additionally, several mutant frequencies (33.9 - 54.4 mutant colonies/106 cells) exceeded the respective historical range of solvent controls. This effect is considered as not being biologically relevant as the mutation frequencies did not exceed the historical data range in the respective parallel culture or the induction factor did not exceed the threshold of three times the solvent control on a reproducible basis.

A linear regression analysis (least squares) was performed to assess a possible dose dependent increase of mutant frequency. No significant dose dependent trend of the mutation frequency indicated by a probability value of <0.05 was determined in any of the experimental groups.

In both experiments of this study (with and without metabolic activation) the range of the solvent controls was from 5.8 up to 45.3 mutant colonies per 106 cells; the range of the groups treated with the test item was from 8.6 up to 54.4 mutant colonies per 106 cells. The highest solvent control after treatment with S9 mix in experiment I and without S9 mix in experiment II (45.3 and 38.4 mutant colonies per 106 cells, respectively) exceeded the historical range of solvent control slightly (3.0 - 33.2 and 3.9 - 31.5 colonies per 106 cells). However, this effect was judged as irrelevant since it is very minor and the corresponding solvent control remained well within the range of historical controls.

Acceptability

The study is considered acceptable.

Conclusions

In this study, BCS-AA56716 has no mutagenic potency in vitro in the CHO/HGPRT assay.

Summary

The results from the available in vitro genotoxicity studies with BCS-AA56716 are summarised in table 6.8.1.1-6, respectively.

Table 6.9.1.2-6 In vitro genotoxicity studies

Test substance	Type of study		Result		Reference
	Indicator cells	Endpoint	without activation	with activation	
BCS-AA56716	S. typh. TA 98 TA 100 TA 102 TA 1535 TA 1537	Point mutation	-	-	Sokolowski, A. (2010)
BCS-AA56716	Chinese hamster V79 cells	Chromosome aberration	-	-	Hall, C. (2010)
BCS-AA56716	Chinese hamster V79 cells	Gene mutations (HGPRT)	-	-	Hall, C. (2010)

BCS-AA56716 was not mutagenic in the Ames test.

BCS-AA56716 did not induce structural chromosome aberrations in V79 cells and showed no mutagenic potency in vitro in the CHO/HPRT assay.

Species	:	Rat, Wistar RJ: WI (IOPS HAN)	acceptability	:	Yes as preliminary
group size	:	5/sex/dose	**NOAEL**	:	500 ppm (51 mg/kg bw/day)

Study design

5 rats per sex per dose group were assigned to dose groups using a randomization by weight. BCS-AA56716 was administered in the diet for 14 days to Wistar rats at the following doses: 0, 500, 2000 and 8000 ppm (equating to approximately 0, 48, 187 and 745 mg/kg/day in males and 0, 51, 201 and 800 mg/kg/day in females). A negative control group received plain diet.

Animals were observed daily for mortality and clinical signs. Physical examinations were performed at least weekly. Body weight and food consumption were recorded once weekly. Hematology and clinical chemistry parameters were determined at the end of the study. All animals were necropsied, selected organs weighed and a range of tissues were taken, fixed and examined microscopically.

Results

Table 6.8.1.3-1

*p≤0.05 **p≤0.01

BCS-AA56716 dietary administration at dose levels of 0, 500, 2000 and 8000 ppm to males and females Wistar rats for at least 14 days induced no treatment-related changes with regard to survival, clinical signs, food consumption, hematological parameters, macroscopic observation and microscopic examination.

At 8000 ppm, mean body weight was similar to the controls in both sexes on study Day 8 and was slightly reduced by 4% in males and 3% in females on study Day 15 (not statistically significant) in comparison to the controls. This slight effect was attributable to a mean cumulative body weight gain reduced by 13% in males and 12% in females throughout the study (not statistically significant) when compared to the controls. Clinical chemistry revealed a mean glucose concentration reduced by 54% in males and 45% in females (p <0.01) compared to the controls. In addition, mean urea concentration was 27% higher in females (not statistically significant) in comparison to the controls. At necropsy, mean terminal body weight was lower by 6% in males and 7% in females (not statistically significant), compared to the controls. Lower mean total bilirubin concentrations (- 45%, p <0.05) were also noted at 8000 and 500 ppm. In the absence of a dose-effect relationship, these variations were considered not to be treatment related.

At 2000 ppm, mean body weight parameters were unaffected by treatment in males, whilst in females a marginal reduction in mean cumulative body weight gain was noted throughout the study (- 12% compared to the controls, not statistically significant). Clinical chemistry revealed a mean glucose concentration reduced by 41% in males and 48% in females (p <0.01) compared to the controls. In addition, mean urea concentration was 25% higher in females (not statistically significant) in comparison to the controls. At necropsy, mean terminal body weight was lower by 6% in females only (not statistically significant) compared to the controls. The change observed in males at this dose level was considered not to be adverse in view of its isolated occurrence and absence of associated histological findings.

At 500 ppm, the only changes noted for clinical chemistry consisted of a mean glucose concentration reduced by 34% in males and 42% in females (p <0.01), together with mean urea concentration higher by 23% in females (not statistically significant) in comparison to the controls. These few changes were considered not to be adverse in view of their isolated occurrence and absence of associated histological findings.

Acceptability

The study was not performed under GLP, but it was performed in a GLP-certified laboratory.

Conclusions

500 ppm (corresponding to 51 mg/kg body weight/day) was considered to be a NOAEL in females based on clinical chemistry changes.

Study 2

Reference	:	[redacted].2012	exposure	:	28 days
type of study	:	90 -days toxicity study	dose	:	0, 200, 1000 and 6000 ppm M: 0, 12.7, 66.2, 380 mg/kg bw/d F: 0, 15.6, 78.7, 472 mg/kg bw/d
year of execution	:	2011	vehicle	:	none
test substance	:	BCS-AA56716 (batch BCOO 5984-5-8, purity 97.1%)	GLP statement	:	Yes
Route	:	Dietary	guideline	:	OECD 408
Species	:	Rat, Wistar Rj:WI (IOPS HAN)	acceptability	:	Yes
group size	:	10/sex/group	**NOAEL**	:	200 ppm (12.7 mg/kg bw/d)

Study design

There were 10 animals of each sex per dose group. Animals were assigned to dose groups using a randomization by weight. BCS-AA56716 was administered in the diet for at least 90 days to Wistar rats at the following doses – 0, 200, 1000 and 6000 ppm (equating to approximately 0, 12.7, 66.2, 380 mg/kg body weight/day in males and 0, 15.6, 78.7, 472 mg/kg body weight/day in females). A negative control group received plain diet.

Clinical signs were recorded daily, and body weight was measured weekly. Food consumption was measured twice weekly during the first 6 weeks of treatment and weekly thereafter. A detailed physical examination was performed once during the acclimatization phase and weekly throughout the study. All surviving animals were subjected to a neurotoxicity assessment (functional observational battery and spontaneous motor activity)) during Week 11 of the study. Ophthalmological examinations were performed on all animals during the acclimatization phase and on all surviving animals of the control and high dose groups during Week 12. Urine samples were collected overnight during the week before necropsy from all surviving animals. Before necropsy a blood sample was collected from the retro-orbital venous plexus of each animal for haematology and clinical chemistry investigations. All animals were necropsied, selected organs weighed and a range of tissues were taken, fixed and examined microscopically.

Results

Table 6.9.1.3-2

Dose (ppm)	**0**		**200**		**1000**		**6000**	
	m	**f**	**m**	**f**	**m**	**f**	**m**	**f**
Mortality	No mortalities							
Clinical signs	No clinical signs during the course of the study							
Body weight	Slight progressive statistically significant (on several occasions) lower mean body weight throughout the study in males and females (see table below) at 1000 and 6000 ppm.							

Dose (ppm)	0		200		1000		6000	
	m	f	m	f	m	f	m	f
Body weight gain (g)	317	133	335	131	255**	121	283	106**
Food consumption	Mean food consumption was affected by treatment in either sex at 1000 and 6000 ppm.							
Ophthalmology	no treatment-related changes at the ophthalmological examinations.							
Urinalysis	Urinalysis revealed higher urinary volumes and lower mean refractive indices in both sexes, lower protein levels in females and lower amounts of usually observed crystals in males, compared to controls. Despite the higher urinary volumes, higher ketone levels were noted in both sexes, in correlation with the low glucose concentrations observed in the serum (See table below).							
FOB	no treatment-related changes at the neurological examinations.							
Haematology	Lower statistical significant hemoglobin concentration and lower mean corpuscular volume were observed at 6000 (-8%; -5% resp.) and 1000 ppm (-9%; -6% resp.) in females only. As a consequence, lower mean corpuscular hemoglobin and lower hematocrit were also noted. These changes were observed with no clear dose-effect relationship.

At 6000 ppm

Mean body weight was decreased by up to 7% in males and 9% in females compared to controls (statistically significant on several occasions for females), the effect being progressive throughout the study. At the end of the treatment (study Day 92), the overall mean body weight gain was reduced by 11% in males and 20% in females (p ≤0.01 for females) compared to controls. Mean food consumption was decreased by up to 9% in males (maximal effect observed on study Day 43) and 13% in females (maximal effect observed on study Day 50) throughout the study, compared to controls. The average decrease over weeks 1 to 13 was of 5% in males and 7% in females.
At the hematological evaluation, lower hemoglobin concentration (- 8%, p ≤0.01) and lower mean corpuscular volume (- 5%, p ≤0.01) were observed in females, together with lower mean corpuscular hemoglobin (- 7%, p ≤0.01) and lower hematocrit (- 6%, p ≤0.01), compared to controls. Clinical chemistry determination revealed lower mean glucose concentrations in both sexes (- 45 and - 53% in males and females, respectively, p ≤0.01), lower total bilirubin concentrations in both sexes (- 56 and - 47% in males and females, respectively, p ≤0.01), slightly higher mean inorganic phosphorus concentrations in both sexes (+ 14%, p ≤0.01 or 0.05) and slightly higher mean urea concentrations in both sexes (+ 18 and + 12% in males and females, respectively, p ≤0.05 in males), compared to controls. Urinalysis revealed higher urinary volumes and lower mean refractive indices in both sexes, lower protein levels in females and lower amounts of usually observed crystals in males, compared to controls. Despite the higher urinary volumes, higher ketone levels were noted in both sexes, in correlation with the low glucose concentrations observed in the serum.
At necropsy, a lower mean terminal body weight was observed in males (- 9%, p≤0.05) and females (- 10%, p≤0.01) when compared to the controls. The few organ weight changes noted were considered to be incidental or attributable to the lower mean terminal body weight. At the macroscopic observation, a few black foci were noted in the glandular part of the stomach in both sexes, in correlation with a few cases of focal glandular erosion/necrosis observed at the microscopic examination.

At 1000 ppm

Mean body weight was decreased by up to 13% in males and 6% in females compared to controls (statistically significant on several occasions). The effect was progressive in both sexes throughout the study, but was slightly more marked in this mid dose male group than at the high dose. At the end of the treatment (study Day 92), the overall mean body weight gain was reduced by 20% in males and 7% in females (p ≤0.01 for males) compared to controls. Mean food consumption was decreased by up to 7% in males (maximal effect observed on study Day 43) and 10% in females (maximal effect observed on study Day 50) throughout the study, compared to controls. The average decrease over weeks 1 to 13 was of 5% in males and 4% in females.
At the hematological evaluation, lower hemoglobin concentration (- 9%, p ≤0.01) and lower mean corpuscular volume (- 6%, p ≤0.01) were observed in females, together with lower mean corpuscular hemoglobin (- 8%, p ≤0.01) and lower hematocrit (- 7%, p ≤0.01). These changes were observed with no clear dose-effect relationship. Clinical chemistry determination revealed lower mean glucose concentrations in both sexes (- 45 and - 49% in males and females, respectively, p ≤0.01), lower total bilirubin concentrations in both sexes (- 52 and - 37% in males and females, respectively, p ≤0.01) and slightly higher mean urea concentrations in both sexes (+ 26 and + 23% in males and females, respectively, p ≤0.01) with no clear dose-effect relationship when compared to controls. Urinalysis revealed higher urinary volumes and lower mean refractive indices in both sexes, lower protein levels in females and lower amounts of usually observed crystals in males compared to controls. Despite the higher urinary volumes, higher ketone levels were noted in both sexes, in correlation with the low glucose concentrations observed in the serum.
At necropsy, a lower mean terminal body weight was observed in males (- 15%, p≤0.01) and females (- 7%, p≤0.05) when compared to the controls. The few organ weight changes noted were considered to be incidental or attributable to the lower mean terminal body weight. At the macroscopic observation, a few black foci were noted in the glandular part of the stomach in one or two animals from both sexes (including one control female), in correlation with focal glandular erosion/necrosis observed at the microscopic examination.

<u>At 200 ppm</u>
Treatment-related effects were noted only in the clinical chemistry determination, which revealed lower mean glucose concentrations in both sexes (- 29 and - 27% in males and females, respectively, p ≤0.01), lower total bilirubin concentrations in males (- 27%, p ≤0.05) and slightly higher mean urea concentrations in both sexes (+ 15 and + 14% in males and females, respectively, p ≤0.05). However, these changes are considered not to be adverse effects of the test substance as they do not represent any functional impairment in the test organism since no concomitant change was noted in creatinine concentrations or at the histological examination.

Acceptability
This study is considered acceptable.

Conclusion

The dose level of 200 ppm (equating to 12.7 and 15.6 mg/kg body weight/day in males and females, respectively) was considered to be a NOAEL in male and female Wistar rats, based on the minor changes noted at the clinical chemistry determination.

type of study	:	Acute oral toxicity study	doses	:	300, 2000 mg/kg bw
year of execution	:	2011	vehicle	:	Purified water
test substance	:	BYI 02960-difluoroethyl-amino-furanone (batch NLL 8671-6-1, 98.5% purity	GLP statement	:	Yes
route	:	Oral	guideline	:	According to OECD 423
species	:	Rj Han: SD (IOPS Han)	acceptability	:	Acceptable
group size	:	3f/dose	**LD50-cut off**	:	>2000 mg/kg bw

Study design

The study was performed in accordance with OECD 423.

Three groups of three fasted, young adult female Sprague Dawley rats were given successively a single oral dose of BYI 02960-difluoroethyl-amino-furanone (batch NLL 8671-6-1, 98.5% purity) in purified water of 300, 2 000 and then 2000 mg/kg bw and were observed for 14 days. The substance was tested using a stepwise procedure, each step using three female rats. The animals were assigned to their groups by randomization based on a computerized random procedure. Following an overnight fast (18 hours), the first group received a single dose of 300 mg/kg of BYI 02960-difluoroethyl-amino-furanone (98.5% purity) by gavage. The test substance was administered in drinking water treated by reverse osmosis at a volume of 10 mL/kg bw. After the first assay, as no deaths occurred, another assay was carried out on three animals at the next higher dose-level (2000 mg/kg). After the second assay, as no deaths occurred, the results were confirmed in three other females at the dose-level of 2000 mg/kg. Clinical signs and mortality rates were determined several times on the day of administration and subsequently at least once daily for an observation period of at least 14 days. Body weights were recorded on days 1, 8 and 15. On day 15, surviving animals were sacrificed and all animals were necropsied and examined for gross pathological changes.

Results

Table 6.9.2.1-1 Mortality:

Dose mg/kg bw	Mortality	Time of death

1st 300	-	-
2nd 2000	-	-
3rd 2000	-	-

Clinical observations

At 2000 mg/kg, hypoactivity was noted in one female (first assay) between 1 hour and 4 hours after treatment. In the confirmatory assay, piloerection was observed in three females 4 hours after treatment, associated with chromorhynorrhea in one female. No clinical signs persisted on day 2 in these animals.

At 300 mg/kg, no clinical signs were noted in any animals.

Body weight

At 2000 mg/kg, lower mean body weight gain was observed in groups 2 females all over the study period (-28%) and in group 3 females between days 1 and 8 (-19%), when compared to CIT historical control data. These variations were due to lower body weight gain in 2/3 females (first assay) and 1/3 females (confirmatory assay).
Body weight of the animals treated at 300 mg/kg was unaffected by test item treatment, when compared to CIT historical control data.

Necropsy

The few macroscopic findings noted at the end of the treatment period were of those commonly recorded in the Sprague-Dawley rat and none were considered to be related to the test item administration.

Acceptability

This study is considered acceptable.

Conclusions

The LD50-cut off of BCS-AA56716 was found to be between >2000 mg/kg bw.

B.6.9.2.2 Genotoxicity BYI 02960-difluoroethyl-amino-furanone (BCS-CC98193, BYI 02960-DFEAF, M34)

a extensive bacterial growth, manual count

No indication of mutagenic effects of BYI 02960-difluoroethyl-amino-furanone could be found at assessable doses of up to 5000 g/plate in any of the Salmonella typhimurium strains used in the assay.

Acceptability

The study is considered acceptable.

Conclusions

BYI 02960-difluoroethyl-amino-furanone is not mutagenic in the Ames test.

Study 2

Study design and results

Type of study: mammalian cells in vitro, cytogenetic assay

Indicator cells	Endpoint	Res. -act.	Res. +act.	Activation		Dose range	Reference

a Inclusive cells carrying exchanges;
b Evaluation of 50 metaphases per culture due to strong clastogenic effects;
c Aberration frequency statistically significant higher than corresponding control values.

In the absence of S9 mix the aberration rates were statistically and significantly increased in all dose groups (6.4 to 1636 µg/mL): 4.0 to 8.5 % aberrant cells, excluding gaps were determined in comparison to the corresponding controls showing 1.0% aberrant cells, excluding gaps. The values of historical control data for chromosomal aberration showed a range from 0.0 to 4.0% aberrant cells, excluding gaps. Therefore, the two test item concentrations showing values of 4.0% aberrant cells, excluding gaps were not biologically relevant. However, all other values clearly exceeded the laboratory's historical data range without showing a clear dose-dependency. Also the number of cells carrying exchanges was distinctly increased after treatment with the test item in the absence of metabolic activation (2.0 to 5.0%) as compared to the solvent control (0.5%).
In the presence of S9 mix the aberration rates were lower than the respective solvent control and remained well within the laboratory's historical data range.

Single increased values of polyploidy metaphases (5.0 to 9.3%) and endomitotic cells (0.9 to 1.7%) were observed in different dose groups as compared to the rates of the solvent controls (4.4 and 0.5%).

Acceptability

The study is considered acceptable.

Conclusions

BYI 02960-difluoroethyl-amino-furanone induced structural chromosome aberrations in V79 cells (Chinese hamster cell line) in the absence of metabolic activation at all tested concentrations.

<u>Study 3</u>

Study design and results

Type of study: mammalian cells in vitro, gene mutation test

Indicator cells	Endpoint	Res. –act.	Res. +act.	Activation		Dose range	Reference
				Tissue	Inducer

a cloning efficiency determined immediately after treatment to measure toxicity;
b cloning efficiency determined after the expression period to measure viability of the cells without selective agent.
n.c.: culture was not continued since a minimum of only four analysable concentrations is required.

No relevant and reproducible increase in mutant colony numbers/106 cells was observed in the main experiments up to the maximum concentration. The mutant frequency generally remained well within the historical range of solvent controls (see below). The induction factor exceeded the threshold of three times the mutant frequency of the corresponding solvent control at 410 and 820 µg/mL in the first culture of the first experiment without metabolic activation. This effect however, was judged as biologically irrelevant since all absolute values of the mutation frequency remained within the range of historical solvent controls. Furthermore, the increase was not reproduced in the parallel culture performed under identical experimental conditions and was not dose dependent as indicated by the lacking statistical significance.

A linear regression analysis (least squares) was performed to assess a possible dose dependent increase of mutant frequency. A significant dose dependent trend of the mutation frequency indicated by a probability value of <0.05 was determined in the first culture of the second experiment without metabolic activation and in the second culture of the second experiment with metabolic activation. Both trends were judged as irrelevant however, as all of the individual levels of the mutation frequency remained well within the range of historical solvent controls.

In both experiments of this study (with and without metabolic activation) the range of the solvent controls was from 6.4 up to 30.0 mutant colonies per 106 cells; the range of the groups treated with the test item was from 5.7 up to 33.2 mutant colonies per 106 cells.

Historical controls:

These values represent the historical control data from 2009 – 2010

Mean value:	358.2	18.0
Standard deviation:	246.6	8.2
Number of studies:	48	48

Acceptability

The study is considered acceptable.

Conclusions

In this study, BYI 02960-difluoroethyl-amino-furanone has no mutagenic potency in vitro in the CHO/HGPRT assay.

Study 4

Datarequirement:

Applicant to provide historical control data for the in vivo micronucleus assay performed with BYI 02960-difluoroethyl-amino-furanone.

In the main study, groups of 7 male mice received twice intraperitoneally administrations of BYI 02960-difluoroethyl-amino-furanone at 125, 250 and 500 mg/kg bw, dissolved in sterile water at 24 hours interval. The volume administered was 10 mL/kg bw. No clinical signs were recorded at 125 mg/kg bw. Clinical signs recorded in animals treated at 250 mg/kg bw were reduction of spontaneous activity, eyelid closure and ruffled fur mainly observed after the first administration. The same clinical signs were recorded in the animals treated at 500 mg/kg bw but after both administration.

In comparison to the corresponding vehicle control values there was no biologically or statistically relevant enhancement in the frequency of the detected micronuclei at any preparation interval and dose level after administration of the test item. The mean values of micronuclei observed after treatment with BYI 02960-difluoroethyl-aminofuranone were below the value of the vehicle control group for the low dose. A dose dependent increase occurred within the three test item dose groups resulting in micronuclei frequencies above the concurrent vehicle group in the mid and high dose groups. However, all values were within the laboratory's historical control data range and additionally, one isolated increased value of micronuclei was observed in the high dose group (animal no. 26) which was still within individual control data and below the lowest value obtained in the positive control data. Therefore, the effect was considered to be not biologically relevant.

The viability of the hepatocytes was not substantially affected by the in vivo treatment with the test item at any of the treatment periods or dose groups. The inter-individual variations obtained for the numbers and the viabilities of the isolated hepatocytes were in the range of the historical laboratory control.

No dose level of the test item revealed UDS induction in the hepatocytes of the treated animals as compared to the current vehicle controls. Neither the nuclear grain counts nor the resulting net grain counts were distinctly increased after in vivo treatment of the animals with the test item at 4 hours or 16 hours, respectively. Net grain counts obtained after treatment with the test item remained consistently negative. In addition, no substantial shift to higher values of percentage of cells in repair was reported.

Acceptability

The study is considered acceptable.

Conclusions

BYI 02960-difluoroethyl-amino-furanone has no potential to induce unscheduled DNA synthesis in hepatocytes of treated rats.

Summary

The results from the in vitro and in vivo genotoxicity studies with BYI 02960-difluoroethyl-amino-furanone are summarised in table 6.8.1.2-8 and 6.8.1.2-9, respectively.

Table 6.9.2.2-9 In vitro genotoxicity studies

Test substance	Type of study		Result		Reference
	Indicator cells	Endpoint	without activation	with activation	
BYI 02960-difluoroethyl-amino-furanone	S. typh. TA 98 TA 100 TA 102 TA 1535 TA 1537	Point mutation	-	-	Sokolowski, A. (2011)
BYI 02960-difluoroethyl-amino-furanone	Chinese hamster V79 cells	Chromosome aberration	+	-	Hall, C. (2011)
BYI 02960-difluoroethyl-amino-furanone	Chinese hamster V79 cells	Gene mutations (HGPRT)	-	-	Wollney, H. (2011)

Table 6.9.2.2-10 In vivo genotoxicity studies

Test substance	Type of study		Result	Reference
	Species	Endpoint		
BYI 02960-difluoroethyl-amino-furanone	Mouse, Crl:NMRI	Micronuclei (bone marrow)	-	[redacted] (2011)

BYI 02960-difluoroethyl-amino-furanone	Rat, Wistar	unscheduled DNA synthesis (UDS)	-	[redacted] (2011)

BYI 02960-difluoroethyl-amino-furanone was not mutagenic in the Ames test.
BYI 02960-difluoroethyl-amino-furanone induced structural chromosome aberrations in V79 cells (Chinese hamster cell line) in the absence of metabolic activation at all tested concentrations.
BYI 02960-difluoroethyl-amino-furanone has no mutagenic potency in vitro in the CHO/HGPRT assay.

BYI 02960-difluoroethyl-amino-furanone has no potential to induce micronuclei in mouse bone marrow cells.
BYI 02960-difluoroethyl-amino-furanone has no potential to induce unscheduled DNA synthesis in hepatocytes of treated rats.

Overall, it can be concluded that BYI 02960-difluoroethyl-amino-furanone has not potential to induce genotoxic effects in vivo.

Study design

BYI 02960-difluoroethyl aminofuranone, a metabolite of BYI 02960 (batch number NLL 8671-12-1: a white powder, 98.9 % w/w purity) was administered continuously via the diet to groups of Wistar rats (5/sex/group) for at least 14 days at concentrations of 0, 1280, 3200, 8000 and 20000 ppm (equating to approximately 0, 135, 339, 736 and 1226 mg/kg body weight/day in males and 0, 135, 335, 741 and 2254 mg/kg body weight/day in females). A similarly constituted group received untreated diet and served as a control. Animals were observed daily for mortality and clinical signs. Physical examinations were performed at least weekly. Body weight was recorded on days -7, 0, 1, 3, 6, 7, 10, 13 and 14. Full feeders were weighed on days -7, 0, 1, 3, 6, 7 and 10 and empty feeders were

weighed on days 0, 1, 3, 6, 7, 10 and 13. Hematology and clinical chemistry parameters were determined at the end of the study. All animals were necropsied, selected organs weighed and a range of tissues were retained in fixative. No histopathological examination was performed.

Results

Table 6.9.2.3-1

Dose (ppm)	**0**		**1280**		**3200**		**8000**		**20000**	
	m	**f**	**m**	**f**	**m**	**f**	**m**	**f**	**m**	**f**
Mortality	No mortalities									
Clinical signs	No clinical signs during the course of the study									
Body weight	Statistically significant lower mean body weight at 3200, 8000 and 20000 mg/kg/day throughout the study in females and at 8000 and 20000 mg/kg/day throughout the study in males. (See table below)

* : p <0.05 ** : p <0.01

There was no unscheduled mortality during the study. There were no clinical signs during the 14-day administration in either the treated, or control animals.

Adverse effects considered related to BYI 02960-difluoroethyl aminofuranone administration under the conditions of this study were noted on the animal body weight and/or body weight gain values in the 3200, 8000 and/or 20000 ppm male and/or female animals, with an apparent dose response.

At 3200 ppm, statistically lower body weight gain was noted in males between Days 0 and 1 (1.4 g *vs.* 7.4 g) as well as when calculated for the whole duration of the study (Days 0 to 14, 78 g *vs.* 94.6 g, p <0.05, 37.04% *vs.* 45.67 %). In the Low-mid dose 3200 ppm Group 3 females, statistically lower

body weights up to -11.93% were recorded approximately after 1 week of treatment on Day 6 and towards the end of the treatment on Days 10, 13 and 14.

At 8000 ppm, statistically lower mean body weights up to -16.48% were noted in the Group 4 males after Day 3 of the treatment, and up to -15.88%, in the females, after Day 6, until its completion on Day 14.
In the 20000 ppm Group 5 animals, body weight loss was noted in both males and females between Days 0 and 14.

The mean daily food consumption evaluated based on the cage-based weekly food consumption of male and female rats was lower than control in the 8000 and 20000 ppm Groups 4 and 5, up to - 59% lower in the males and up to - 25% in the females at 20000 ppm, effects considered possibly associated with test item administration. However, spillage was noted in the High dose Group 5 females and the dose response was not clear.

Statistically lower than control reticulocyte mean values were noted in the 20000 ppm males and 8000 and 20000 ppm females and were regarded as possibly associated with BYI 02960-difluoroethyl aminofuranone administration.

Lower than control glucose blood levels were noted in both males and females in all the dose groups, attaining statistical significance at above and including 3200 ppm in the males, with mean values up to - 49% lower than control, and at all the dose levels tested in the females, with mean values of up to - 52%, $p < 0.01$. Cholesterol mean values increased in the 3200 ppm group and above to up to 65% in the males, and up to 49% in the females. Albumin and A/G ratio were slightly higher than control, attaining statistical significance at 8000 and/or 20000 ppm in the males and in both males and females, respectively.

In addition, higher urea was noted in the 20000 ppm males, and in the 20000, and 8000 ppm females. Potentially test item-related macroscopic changes were observed at necropsy in the High dose group fed diet with 20000 ppm BYI 02960-difluoroethyl aminofuranone. These consisted of small prostate and seminal vesicles in 5/5 males and small spleen, in 2/5 males, were associated with the potential test item related changes in the terminal body weights and correlated with the organ weight changes, however, a definitive attribution cannot be made without histopathological evaluation.

Acceptability

The study was not performed under GLP, but it was performed in a GLP-certified laboratory.

Conclusions

In conclusion, based on the effects noted in the current 14-day preliminary study a NOEL is set at 1280 ppm (equating to 135 mg/kg bw/d) based on the lower blood glucose concentrations in females.

The dose levels selected for the upcoming 28-day dietary study with BYI 02960-difluoroethyl aminofuranone were 200, 800 and 3000 ppm.

Study 2

Study design

BYI 02960-difluoroethyl aminofuranone, a metabolite of BYI 02960 (batch number NLL 8671-12-1: a white powder, 98.9% w/w purity) was administered continuously via the diet to groups of Wistar rats (10/sex/group) for 28 consecutive days at concentrations of 200, 800 and 3000 ppm (equating to approximately 17, 68 and 243 mg/kg body weight/day in males and 19, 76 and 273 mg/kg body weight/day in females). A similarly constituted group received untreated diet and served as a control. Animals were observed daily for mortality and clinical signs. Physical examinations were performed at least weekly. An evaluation for any potential neuro- or ophthalmo-toxicity was conducted on Day 26. Body weight and food consumption were measured at least weekly. Prior to necropsy, the oestrous cycle of all females was evaluated by examination of vaginal smears. Clinical pathology investigations (hematology, coagulation, clinical chemistry and urinalysis) were conducted at the completion of the treatment period, before necropsy on Day 28. At termination, necropsy with macroscopic examination was performed. Weights of selected organs were recorded and representative tissues/organs were sampled and preserved in appropriate fixatives. Full histopathology was performed on the selected list of tissues from the control and high dose animals and on any macroscopic abnormality from all animals.

Results

Dose (ppm)	0		200		800		3000	
	m	f	m	f	m	f	m	f
Organ weight	The values within the normal range and the variations with low magnitude showed no consistent response between genders, (Slightly higher kidney weight adjusted for the terminal body weight in the 3000 ppm male and female animals, but not when adjusted for the brain weight, slightly higher testes and seminal vehicles weights relative to the terminal body weight in the 3000 ppm males, or slightly higher testes, or liver (females) weight relative to the brain weight in the 800 ppm animals, but not in the other gender, and not at 3000 ppm)							
Pathology	No test item-related macroscopic or microscopic findings							

*p≤0.05 **p≤0.01, NC = no significant change

There was no unscheduled mortality during the study, clinical signs, signs of neurotoxicity or any test item related, or adverse effects on the landing foot splay or grip strength under the conditions of this study. Evaluation of the vaginal smears prior to necropsy showed the expected distribution of the oestrus cycle phases within the normal population of female Wistar rats.

There was a slight but not statistically significant trend towards lower body weights at 3000 ppm in both sexes (5 - 6% below control at termination), this body weight effect corresponds with findings in a preliminary study where body weights were 15 - 20% below control at 8000 ppm. There were statistically significantly lower weight gains in both sexes in the first week of the study but the overall weight gains for the study duration were not statistically different. Other statistically significant differences were not considered to be of biological significance.

There were no test item related adverse effects on the animal food consumption during the study. No test-item related adverse effects were noted on the food conversion efficiency FCE values (g/g, calculated as weekly body weight gain g/weekly food consumption g) at any of the dose levels tested and the mean values were similar with the ones recorded in the control group.

The variations in hematological parameter compared to controls were not considered toxicologically significant or related to treatment, in the absence of a consistent dose or gender response and as the individual and mean values remained within the physiological ranges.

No toxicologically significant, adverse effects were noted at evaluation of the clinical chemistry parameters evaluated at up to and including 3000 ppm. No statistically significant differences or toxicologically relevant effects were observed at urinalysis conducted at the completion of the treatment.

No test item-related macroscopic or microscopic findings were observed at the end of the study. There were no changes considered toxicologically significant in the absolute or relative organ weight values, relative to the body or brain weight, noted after BYI 02960-difluoroethyl aminofuranone administration in diet for 28 days, at up to and including 3000 ppm, evaluated immediately after completion of the treatment.

Acceptability

This study is considered acceptable.

Conclusion

Based on body weight effects, the NOAEL is considered to be 3000 ppm equating to approximately 243 mg/kg bw/day for the males and 273 mg/kg bw/day for the females.

B.6.9.3 BYI 02960-CHMP (6-chloropyridin-3-ylmethanol, IM-O, M21)

B.6.9.3.1 Acute toxicity BYI 02960-CHMP (6-chloropyridin-3-ylmethanol, IM-O, M21)

Study 1

Characteristics

reference	:	[redacted] 1993 amended in 1997	exposure	:	Gavage
type of study	:	Acute oral toxicity study	doses	:	M: 1000, 1500, 2000 and 3000 mg/kg bw/d F: 1000, 1300, 1500, 2000, 3000 mg/kg bw/d
year of execution	:	1993	vehicle	:	Ion-exchange water
test substance	:	IM-0((6-chloro-3-pyridyl)methanol, batch N° NK-2327'-6, 98.65% of purity)	GLP statement	:	Yes
route	:	Oral	guideline	:	According to OECD 401
species	:	Crj:CD (SD), SPF	acceptability	:	Acceptable
group size	:	5/sex/group	**LD50-cut off**	:	1,483 mg/kg bw/d

Study design

The study was performed in accordance with OECD 401.

The substance was tested at 1000, 1500, 2000 and 3000 mg/kg in five male and five female Sprague Dawley rats per group, plus an additional group of five females treated at 1300 mg/kg. The animals were randomly allocated to cages. Following an overnight fast, the animals received a single dose of IM-0 (6-chloropyridin-3-ylmethanol, BYI02960-CHMP) by gavage. The test substance was administered in ion-exchange at a volume of 10 mL/kg bw. Clinical signs and mortality rates were determined several times on the day of administration and subsequently at least once daily for an observation period of at least 14 days. Body weights were recorded prior to administration and on

days 1, 2, 3, 7 and 14 and at death except for animals that died on day 0. A gross necropsy was performed on all animals that died during the observation period and on all animals that survived until the termination of the experiment.

Results

Table 6.9.3.1-1 Mortality:

Dose mg/kg bw	Mortality Males	Mortality Females	Time of death
1000	-	-	
1300	Not tested	-	
1500	1/5	3/5	Within 1 day males and 2 days females
2000	3/5	5/5	Within 1 day
3000	5/5	5/5	Within 1 day

Clinical observations

The absence of righting reflex and a decrease in motor activity, hypotonea, prone position and ataxia were observed at all doses in both sexes. All signs disappeared on the next day of the application for the males and on day 2 for the females.

Body weight

No body weight effects were observed in males. A slight body weight loss was observed in 3/5 females treated at 1300 mg/kg and 1/3 females at 1500 mg/kg one day after the administration. The animals from these groups recovered thereafter.

Necropsy

Gastric haemorrhagies were observed in one male and one female treated at 1500 mg/kg.

Acceptability

This study is considered acceptable.

Conclusions

Under the experimental conditions of this study, the acute oral LD_{50} values for IM-0 are 1,842 mg/kg for males and 1,483 mg/kg for females.

Pos. control	87	113	517	563	489	203	615	144	301	574

In the first and second main experiment, no increase in the number of reverse mutant colonies was observed in any strain, either in the presence or absence of metabolic activation.

Acceptability

The study is considered acceptable.

Conclusions

IM-0 is not mutagenic in the Ames test.

B.6.9.3.3 Short-therm toxicity BYI 02960-CHMP (6-chloropyridin-3-ylmethanol, IM-O, M21)

Study 1

Characteristics

Reference	:	[redacted]; 1993 amended in 1997	exposure	:	90 days
type of study	:	Thirteen-week dietary subchronic toxicity study in rats	dose	:	0, 160, 800, 4000 and 20 000 ppm (corresponding to 0, 9.9, 48.9, 250.1 and 1246.6 mg/kg/day for males and 0, 11.1, 55.9, 275.9 and 1173.7 mg/kg/day for females)
year of execution	:	1993	vehicle	:	none
test substance	:	BYI 02960-CHMP (IM-0 or , 6-chloropyridin-3-ylmethanol) (batch number NK-3266 (Tox-563): a pale yellow crystal, 98.94% purity),	GLP statement	:	Yes
Route	:	diet	guideline	:	OECD 408
Species	:	Rat, Crj:CD^{TM} (SD)	acceptability	:	yes
group size	:	10/sex/dose	**NOAEL**	:	800 ppm (48.9 mg/kg/day)

Study design

BYI 02960-CHMP (IM-0 or 6-chloropyridin-3-ylmethanol) (batch number NK-3266 (Tox-563): a pale yellow crystal, 98.94% purity), a metabolite of the insecticide BYI 02960, was administered continuously via dietary administration to separate groups of Sprague Dawley rats (10/sex/group) at concentrations of 160, 800, 4000 and 20 000 ppm (corresponding to 9.9, 48.9, 250.1 and 1246.6 mg/kg/day for males and 11.1, 55.9, 275.9 and 1173.7 mg/kg/day for the females) for at least 90 days. A similarly constituted group of 10 males and 10 females received untreated diet and acted as a control.

Clinical signs were recorded daily and body weight and food consumption were measured weekly. A detailed physical examination was performed weekly throughout the study. Ophthalmological examinations were performed on the animals from the control group and the high dose group during

the acclimatization phase and during Week 12. Urine samples were collected overnight during the week before necropsy from all animals. Before necropsy a blood sample was collected from the carotid artery of each animal for haematology and clinical chemistry investigations. All animals were necropsied, selected organs weighed and a range of tissues were taken, fixed and examined microscopically.

Results

Table 6.9.3.3-1

Dose (ppm)	**0**		**160**		**800**		**4000**		**20000**	
	m	**f**	**m**	**f**	**m**	**f**	**m**	**f**	**m**	**f**
Mortality	No mortalities									
Clinical signs	Abnormal teeth, alopecia and excoriation in males, and alopecia, reddening in auricles, crust, lacrimation and abnormal teeth in females were sporadically seen in all groups, and the incidences were not treatment-related .									
Body weight	Statistically significant lower mean body weight at 20000 mg/kg/day throughout the study in males and females at study termination.									
Mean body weight (g) Relative ratios (%0 to control values	585.4	317.6	578.3 (99)	300.6 (95)	622.7 (106)	318.0 (100)	613.0 (105)	301.3 (95)	455.3 (78)**	243.3 (77)**
Food consump-tion	Mean food consumption was affected by treatment in either sex. Mean food consumption values (g/animal/day) of 20000 ppm males and females were decreased throughout the study when compared with the control, and attained statistical significance at weeks 1-4, 6, 9 and 13 in males and at every week in females. Mean food consumption values (g/kg/day) of 20000 ppm males were significantly decreased at the early phase of treatment (at weeks 7-8 and 12), while that of females in this group was significantly decreased at weeks 1, 2, 4, 8, 9 and 12.									
Ophthal-mology	At the examination performed prior to the study initiation, red areas in cornea were observed in two males, one from control and another from 20000 ppm group. At week 12 examinations, no effects of test compound treatment were evident in the males and females of 20000 ppm groups, compared to control.									
Urinalysis	No treatment related changes									
FOB	Not determined									
Haematolo gy	No treatment related changes.

Pathology										
Macros-copy	No treatment related changes									
Microscopy	Test compound related lesions, consisted of eosinophilc intranuclear inclusions in the proximal tubular epithelium, were seen only in the kidney of males in the 4000 (70%) and 20000 (100%) ppm groups and in females in the 20000 (90%) ppm group.									

*p≤0.05 **p≤0.01

There were no signs of reaction to treatment in any treated group. All animals survived throughout the study.

Mean body weights for high dose (20 000 ppm) males and females were significantly less than respective control groups throughout the study. Mean body weights of the high dose groups were 78% of control values in males, and 77% in females. Mean body weight gains of the high dose groups were 67% of control values in males, and 57% in females.

Food consumption values of these groups were lower than control values at weeks 1-4, 6, 9, 13 (days 7 - 28, 42, 63, 91) examinations in males, and at all weeks in females. Food efficiency values of the 20 000 ppm animals were significantly decreased at weeks 1 and 10 (days 7 and 70) in males, and at week 1 (day 7) in females.

No treatment-related effects were observed at ophthalmological, haematological or urinalysis evaluations. A statistically significant increase in serum alkaline phosphatase activity was seen only in the 20000 ppm group females at study termination.

Statistically significant decreases in mean absolute weights of lung (male only) and liver (male only), and statistically significant increases in mean relative organ weight ratios of brain (both sexes), lung

(females only), liver (females only), kidney (both sexes) and testis (right side only) were seen only in 20000 ppm groups. However, these changes were attributed to the decreased body weights in these groups (reduction rates, 21% in males, 22% in females).
Necropsy revealed no compound-related lesions. Histologically, dose-related eosinophilic intranuclear inclusions were seen in the proximal tubular epithelium of kidneys for 20000 ppm males and females and 4000 ppm males. Other microscopic changes were occasionally seen in the control and treated groups, but they were considered unrelated to treatment with test compound.

Acceptability

This study is considered acceptable.

Conclusions

Based on the results mentioned above, the effects of the test item (IM-0), when administered in the diet to Sprague Dawley rats for 13 weeks, were decreased body weight gains, decreased food consumption values, increased serum alkaline phosphatase activity, and eosinophilic intranuclear inclusions in the proximal tubular epithelium of kidney. The NOAEL is 800 ppm (48.9 mg/kg/day) in males, and 4000 ppm (275.9 mg/kg/day) in females.

species	:	Crj:CD (SD), SPF	acceptability	:	Acceptable
group size	:	5/sex/group	**LD50-cut off**	:	>5000 ppm

Study design

The study was performed in accordance with OECD 401.

The substance was tested at 2000 and 5000 mg/kg in five male and five female Sprague Dawley rats per group. The animals were randomly allocated to cages. Following an overnight fast, the animals received a single dose of IC-0 (6-chloronicotinic acid, BYI02960-6-CNA) by gavage. The test substance was administered in Tween 80 - ion-exchange water at a volume of 10 mL/kg bw. Clinical

signs and mortality rates were determined several times on the day of administration and subsequently at least once daily for an observation period of at least 14 days. Body weights were recorded prior to administration and on days 1, 2, 3, 7 and 14 and at death except on day 0. A gross necropsy was performed on all animals that died during the observation period and on all animals that survived until the termination of the experiment.

Results

Table 6.9.4.1-1 Mortality:

Dose mg/kg bw	Mortality Males	Mortality Females	Time of death
2000	-	-	
5000	-	-	

Clinical observations

No signs of toxicity were observed in any groups of either sex.

Body weight

No unusual changes in body weight were observed in 2,000 mg/kg in males. Body weights in 5,000 mg/kg males decreased on day 1 to day 2 after the administration, and recovered from day 3. Body weights in 2000 mg/kg females decreased on day 1 after the administration. Body weights in 5,000 mg/kg females decreased on days 1 to 3 after the administration and recovered thereafter.

Necropsy

No abnormality was observed in any rats at necropsy.

Acceptability

This study is considered acceptable.

Conclusions

Under the experimental conditions of this study, the acute oral LD_{50} value of IC-0 in rats is greater than 5000 mg/kg for both sexes.

B.6.9.4.2 Genotoxicity BYI 02960-6-CNA (6-chloronicotinic acid, IC-0, M27)

Study 1

Summary

BYI 02960 is a new insecticide being developed by Bayer CropScience; a full toxicological package has been performed for registration purposes. Difluoroacetic acid is a plant and livestock metabolite of BYI 02960 and a major environment metabolite, having been found in soil metabolism studies at > 10% of applied dose. Additionally, DFA is a groundwater metabolite with a PECgw between 0.75 µg/L and 10 µg/L based on calculations according to EU models. DFA was detected in the rat ADME studies at approximately 6% of the administered dose. However since DFA was not found in the rat ADME studies above 10% of the applied dose, based upon EFSA guidance, select toxicology studies were conducted with DFA to compare its toxicological properties with those of parent compound BYI 02960 and to exclude that DFA is a relevant metabolite according to the EU Guidance document on the assessment of the relevance of metabolite in groundwater (Sanco/221/200 rev. 10). DFA has been tested in an acute oral rat study, *in vitro* genotoxicity studies and in a subchronic rat toxicity study. The purpose of this position paper is to demonstrate that the toxicological profile of DFA

is very similar to that of BYI 02960 and DFA should therefore be considered to be covered by the overall toxicological profile of the parent compound.

Acute toxicity studies

BYI 02960 (1) was administered to four groups of three Wistar female rats at 2000 mg/kg and 300 mg/kg(two groups of three animals for each concentration). In the groups treated at 2000 mg/kg, four of six animals died within 2 or 3 hours after administration. The following clinical signs were noted at this concentration: decreased motility, tremors, piloerection, labored breathing and clonical cramps. There was no effect on body weight and no necropsy findings in surviving animals. In the other animals, black liver or liver with black spots and hemorrhagic lung were observed.
No mortality was observed at 300 mg/kg. Clinical signs were limited to breathing sounds. No effects on body weight and no necropsy abnormalities were recorded.

Difluoroacetic acid (2) was administered to three groups of three Sprague-Dawley female rats at 2000 and 300 mg/kg (one group for 2000 mg/kg and two groups for 300 mg/kg). In the group treated at 2000 mg/kg, two of three animals died within 1 hour after administration, showing hypoactivity, dyspnea and/or lateral recumbency within 25 minutes prior to death. Sedation, then hypoactivity, lateral recumbency, dyspnea, piloerection and staggering gait were observed in the surviving animal from day 1 to day 9. Body weight loss of 8% was also observed at the end of the first week, but body weight gain returned to normal thereafter. No abnormality was recorded at necropsy.
No mortality was observed at 300 mg/kg. Clinical signs were limited to loud breathing in one female on day 3. Overall body weight gain was not affected and no abnormalities were recorded at necropsy.

From these two studies it can be concluded that BYI 02960 and difluoroacetic acid have a similar profile for acute toxicity. Both compounds are classified category IV according to the GHS classification system.

Genotoxicity studies

BYI 02960 was tested in four genotoxicity studies: three *in vitro* and one *in vivo* study. All of them were negative. BYI 02960 was tested at doses of up to 5000 g/plate on Salmonella typhimurium strains TA1535, TA100, TA1537, TA98 and TA102 (3), and at up to 10mM in the HPRT test (4) and the chromosome aberration test (5). In the *in vivo* micronucleus test on NMRI mice (6), three dose levels were tested: 10, 20 and 40 mg/kg (two injections at a 24-hour interval).

Difluoroacetic acid was tested in three *in vitro* studies. As all studies were negative, no further testing was done. Difluoroacetic acid was also tested at up to 5000 g/plate on Salmonella typhimurium strains TA1535, TA100, TA1537, TA98 and TA102 (7), and at up to 10mM in the HPRT test (8) and the chromosome aberration test (9).

Both compounds are not genotoxic.

Subchronic rat toxicity studies

BYI 02960 was administered to groups of 10 male and 10 female Wistar rats at 100, 500 and 2500 ppm over a period of at least 90 days. These dose levels equate to 6, 30 and 156 mg/kg/day in males and 7.6, 38 and 186 mg/kg/day in females. Effects are summarized below.

Table 6.9.6-01: Significant changes in the 90-day rat study with BYI 02960

Conclusion

Although slightly different findings were observed in each of the 90-day rat studies, the overall toxicological profile is very similar. Therefore, we consider that difluoroacetic acid is covered by the toxicological endpoints obtained with the parent compound, BYI 02960. The compounds are of similar acute toxicity, although no clinical signs or neurotoxic effects were observed after difluoroacetic acid administration. The metabolic changes observed with difluoroacetic acid were also observed with BYI 02960 in a 28-day rat study (12) at 5000 ppm, where a marked decrease in total bilirubin (- 73%) and glucose (- 46%) and a significant increase in urea (+ 37%) and total cholesterol (+ 41%) compared to controls were observed at 5000 ppm. The most significant effect detected is the decrease in glucose, which however did not cause any change in the behavior of the animals nor did it cause any functional impairment. Furthermore, a decrease in glucose was also observed in the parent 90-day study after administration of BYI 02960 at 2500 ppm and this decrease in glucose was reversible as no significant change was observed at the end of a 28-day recovery period. Also, in the

2-year rat study, a decrease in glucose was observed in both males and females treated at 2000 ppm after 3 months of administration (- 23% in males and - 18% in females) and in males only after 6 months (- 16%) but no significant variations were observed thereafter (13). Therefore, the effect on glucose should be considered adaptative as demonstrated in the combined rat chronic toxicity and carcinogenicity study. The effects observed in the stomach after DFA administration are very minor lesions which could be due to stress and which are only seen at quite high dose levels and with very low incidence

In conclusion, no separate risk assessment for difluoroacetic acid is considered necessary. Risk assessment can be performed on the basis of total residue (as defined in the residue definition) and based upon parent ADI and ARfD.

Background

The parent compound BYI 02960 shows a quite extensive metabolic behaviour in crops, and also in livestock, whereas metabolisation was less pronounced in the rat. Thus several plant and/or livestock metabolites were not detected as systemic metabolites in the rat ADME studies. To assess the possible health risk due to the dietary exposure to these metabolites, a new conservative risk assessment approach has been applied on basis of the scientific report “Impact of metabolic and degradation processes on the toxicological properties of residues of pesticides in food commodities” prepared by the Institute for Plant Protection Product Evaluation and Authorisation of the Austrian Agency (AGES, 2010) and the EFSA draft scientific opinion on “Exploring options for providing preliminary advice about possible human health risks based on the concept of Threshold of Toxiclogical Concern (TTC)”. These scientific reports refer to a decision tree which allows the evaluation of the human safety on basis of the exposure to a metabolite.
According to this approach no additional toxicity data are needed for a metabolite, if

(1) the dietary metabolite was detected as systemic metabolite in the rat ADME study and accounted for >10% of the administered dose,

(2) the metabolite shows structural similarities to the parent/precursor and if the metabolic pathway from parent/precursor to the questioned metabolite is simple and it is unlikely that the metabolisation step causes toxification (e.g. demethylation, hydroxylation of a ring system),

(3) the consumer is not exposed to this metabolite, i.e. that it accounts for <0.01 mg/kg in food items and <0.05 mg/kg in feed items, or

(4) the metabolite is considered not to be geno- or neurotoxic (based on DEREK) and the consumer exposure is assumed to be below the threshold of toxicological concern (TTC) for Cramer Class III compounds (<1.5 µg/kg bw/day, or 90 µg/person/day).

Evaluation of the toxicological coverage of BYI 02960 metabolites

(1) Dietary metabolites covered by the rat ADME studies

BYI 02960 was moderately metabolised in the rat. The parent compound represented the predominant part of the radioactivity in urine (the preferred route of excretion) of male and female rats. The main metabolite detected in urine and faeces was BYI 02960-OH, which accounted for 11% to 29% of the dose administered in excreta. Thus BYI 02960-OH was present in sufficient amount to contribute to the toxicological effects when testing the parent compound.
The two metabolites, 6-CNA (<1% to 6%) and BYI 02960-hippuric acid (1% to 11%) were also prominent in male but not in females rats. In sum the metabolites represented 10% to 16% of the administered dose in male rats. Since BYI 02960-hippuric acid can be formed from 6-CNA only, the proportion of BYI 02960-hippuric acid can be added to the 6-CNA proportion. Thus, when considering the two metabolites together, 6-CNA accounted for ≥10% of the dose administered dose in male rats. Since there is no sex difference in the toxicological profile of BYI 02960, it can be concluded that the proportion of 6-CNA in rat excreta is adequately addressed. Thus 6-CNA was present in a sufficient concentration to contribute to the toxicological effects when testing the parent compound.
All other metabolites detected in the rat ADME represented less than 5% of the administered dose.

(2) Metabolites showing structural similarity to parent/precursors and arising from metabolisation steps which will cause no toxification

Conjugation of metabolites is in general a detoxification step. Thus it can be considered that the toxicity of a conjugate is covered by its aglycon. Therefore, the toxicity of the conjugates of BYI 02960-OH (isomers of BYI 02960-OH-gluA, BYI 02960-OH-SA, BYI 02960-OH-glyc, isomers of BYI 02960-OH-glyc-SA) and of 6-CNA (6-CNA-glycerol-gluA) detected in plants and livestock can be considered as toxicologically covered.

(3) Metabolites showing no consumer exposure

For the exposure we would like to refere to the residue section. In summary, based on the residues levels detected in the livestock metabolism studies, it was assumed that most of the metabolites detected show no consumer exposure under real conditions. The highest residues in the goat matrices were estimated for parent compound, metabolite BYI 02960-OH and its glucuronic acid conjugates. BYI 02960-OH was detected in the rat ADME study, as well as two isomers of its glucuronic acid conjugate and thus a toxicological coverage is given.

In poultry none of the metabolites detected in the samples of the metabolism studies would exceed a residue level of 0.010 mg/kg under real conditions, except for the fatty acids which were detected in high concentrations in eggs, fat and liver. However since fatty acids as natural compounds do not exhibit any toxicological concern.

(4) Metabolites with a consumer exposure below the threshold of toxicological concern

The threshold of toxicological concern (TTC) is based on the concept that there are levels of exposure to chemicals that will result in no appreciable risk to health. The classification of chemicals according to their chemical structure is an important component of the current TTC approach. The classification scheme most widely used is that described by Cramer et al. (1978). Plant metabolites and degradates of pesticide active substances are assigned to Cramer Class III. The corresponding dietary exposure threshold is **1.5 µg/kg body weight per day** for substances with no structural alerts for genotoxicity and neurotoxicity. Neonicotinoids and pyrethroids are included in Cramer Class III according to the Scientific Report “Applicability of thresholds of toxicological concern in the dietary risk assessment of metabolites, degradation and reaction products of pesticides”, published by CRD in 2009. There is no reason to include them in the neurotoxic TTC grouping, with a threshold value of 0.3 µg/kg body weight per day.

In accordance with this concept, a two-step approach was applied for all BYI 02960 metabolites for which a consumer exposure was expected and no toxicological coverage was proven (by the rat ADME studies or additional toxicological testings).

1. Exclusion of genotoxicity:
   Each metabolite was tested for genotoxic alerts by DEREK. DEREK is a commonly used *in silico* expert system for the qualitative prediction of toxicity.
2. Estimation of the possible consumer exposure
   Based on the EFSA Pesticide Residue Intake Model (PRIMo), the possible consumer exposure of a metabolite or a group of metabolites was estimated. Conjugates and their aglycons were considered as a metabolite group and their concentrations (in mg a.s. equiv./kg) were summed up for a combined evaluation. Metabolites resulting from the same metabolic path were also considered as a metabolite group. For the estimation of the possible consumer exposure we would like te refere to the residue section. In conclusion: the consumer exposure to the metabolite group consisting of:

(1) BYI 02960-bromo/-chloro, BYI 02960-bromo-amino-furanone and BYI 02960-amino-furanone,
(2) BYI 02960-mercapto-lactic acid,
(3) BYI 02960-acetic acid and -acetic acid-glyc, and
(4) BYI 02960-glyoxylic acid, BYI 02960-AMCP-difluoroethanamine, BYI 02960-N-formyl- and BYI 02960-N-acetyl-AMCP-difluoroethanamine

are below the threshold of toxicological concern of 1.5 µg/kg bw/day.

(5) Metabolites with additional toxicity testing

Due to various considerations, additional toxicity studies were initiated for the metabolite difluoroacetic acid (a major soil metabolite with the potential, according to FOCUS groundwater modelling, to leach into shallow groundwater at concentrations of > 0.75 mg/L) and metabolite BYI 02960-difluoroethyl-amino-furanone (a proposed constituent of the residue definition for data collection in target and rotational crops; it was observed in the rat ADME study at levels less than 5% of the administered dose). Additional toxicity data are also available on metabolites BYI 02960-CHMP and 6-CNA. They are common metabolites with the active substance acetamiprid and several toxicological studies had been conducted for the submission of this insecticide. As described in detail in Section 3, KIIA 5.8, none of theses metabolites are acutely toxic or exhibit a genotoxic potential. The metabolites tested after subchronic (difluoroacetic acid, BYI 02960-CHMP) or subacute (BYI 02960-difluoroethyl-amino-furanone) administration to the rat were less toxic than BYI 02960 and are thus covered by the endpoints derived for the parent compound BYI 02960.

(6) Metabolites of no toxicological concern

For the natural compounds glucose, lactose and fatty acids no estimation of residue levels was considered necessary since they are of no toxicological concern.

Conclusions

A health risk due to the dietary exposure to plant and livestock metabolites of BYI 02960 can be excluded on basis of the data presented. All metabolites detected show either a consumer exposure below the agreed threshold level of toxicological concern (<1.5 µg/kg bw), or it has been shown that the metabolites are covered by the endpoints derived for the parent compound BYI 02960.

An overall evaluation of the plant and livestock metabolites is summarized in Table 5.11-13.

B.6.10 MEDICAL DATA AND INFORMATION (ANNEX IIA 5.9)

B.6.10.1 Medical surveillance on manufacturing

The active ingredient has been produced in 2 campaigns in 2008 and 2010. Routine occupational medical examinations of the workers involved in production, not directly correlated to the campaigns, showed no abnormalities.

B.6.10.2 Clinical cases of poisoning incidents

As the active ingredient has not yet been marketed, no such experiences exist.

B.6.10.3 Observations on exposure of the general population

As the active ingredient has not yet been marketed, no such experiences exist.

B.6.10.4 Clinical signs and symptoms of poisoning and details of clinical tests

As no poisonings in human have occurred, no information is available

B.6.10.5 First aid measures and therapeutic regimes

- Remove patient from exposure/terminate exposure under self-protection
- Thorough skin decontamination with copious amounts water and soap, if available with polyethylenglykol 300 followed by water
  Note: Most formulations with this active ingredient can be decontaminated with water (and soap), so for formulations polythyleneglykol 300 is not required
- Flushing of the eyes with lukewarm water for 15 minutes
- Induction of vomiting should only be considered if a significant amount has been swallowed (more than a mouthful), if the ingestion was less than one hour ago, and if the patient is fully conscious. Induced vomiting can remove maximum 50% of the ingested substance. Note: Induction of vomiting is forbidden, if a formulation containing organic solvents has been ingested!

B.6.10.6 Expected effects of poisoning

As no poisonings in human have occurred, no information is available.

B.6.11 SUMMARY OF MAMMALIAN TOXICOLOGY AND PROPOSED ADI, AOEL, ARFD AND DRINKING WATER LIMIT (ANNEX IIA 5.10)

B.6.11.1 Toxicokinetics

Absorption, distribution, excretion and metabolism of flupyradifurone was investigated using three different labelling positions. The active substance was labelled with ^{14}C in the pyridinylmethylene bridge, in the 4-position of the furanone ring and in the 1-position of the ethyl side chain:

Pyridinylmethyl-^{14}C flupyradifurone | Furanone-4-^{14}C flupyradifurone | Ethyl-1-^{14}C flupyradifurone

The pyridinylmethyl-labelled compound was used in an ADME-study in which male and female rats were orally administered with a single low dose of 2 mg/kg bw or a high dose of 200 mg/kg bw. Due to the high water solubility of flupyradifurone, male rats were also given an intravenous dose of 2 mg/kg bw. In this study, the excretion via urine and faeces was investigated as well as the distribution in the plasma and the radioactivity concentration in organs and tissues at sacrifice. The metabolism was investigated in urine and faeces.

A quantitative whole body autoradiography study was conducted also using the pyridinylmethyl-labelled compound following a single oral dose of 5 mg/kg bw to male and female rats. In this study the excretion of radioactivity was determined in urine, faeces and expired air, as well as the distribution in the plasma and the radioactivity concentration in the organs and tissues at various time points.

The furanone-4-labelled compound was used in an ADME-study in which male and female rats were orally administered with a single dose of 2 mg/kg bw. In this study, the excretion via urine and faeces was investigated as well as the distribution in the plasma and the radioactivity concentration in the organs and tissues at sacrifice. The metabolism was investigated in urine and faeces.

A quantitative whole body autoradiography study was also conducted using the furanone-4-labelled compound following a single oral dose of 5 mg/kg bw to male and female rats. In this study the excretion of radioactivity was determined in urine, faeces and the expired air as well as the distribution in the plasma and the radioactivity concentration in the organs and tissues at various time points.

In an organ metabolism study, male and female rats were orally administered with a single dose of 3 mg/kg bw [furanone-4-^{14}C] flupyradifurone. Animals were sacrificed 6 hours after dosage and the metabolism was investigated in urine, plasma, and in extracts of liver, kidney, muscle and fat tissues.

The ethyl-1-labelled compound was used in an ADME-study in which male rats were orally administered with 2 mg/kg bw. In this study, the excretion via urine, faeces and expired air was investigated as well as the distribution in the plasma and the radioactivity concentration in the organs and tissues at sacrifice. The metabolism was investigated in urine and faeces.

In an organ metabolism study, male and female rats were orally administered with a single dose of 3 mg/kg bw [ethyl-1-^{14}C] flupyradifurone. The animals were sacrificed at 1, 6 or 24 hours after dosing. The total radioactivity was determined over the different time periods in urine, while in plasma, liver, kidney, muscle and fat tissue at different time points after sacrifice. The metabolism was investigated in urine, plasma, and in extracts of liver, kidney, muscle, and fat tissue.

Absorption

Following oral administration of a single low dose of flupyradifurone to male and female rats, the gastrointestinal absorption of radioactivity was high. It accounted for >80 % of the dose independent of the labelling position used. The value of >80% can be used for further toxicological risk assessment.

Distribution

The maximum plasma concentration was reached in most cases within 1 or 2 hours after administration of low doses. Only after administration of the high dose of 100 mg/kg bw the peak plasma concentration was observed between 2 and 4 hours after dosage. After reaching the peak concentration, the radioactivity levels in plasma declined steadily by several orders of magnitude in all studies independent of sex or labelling position of the test compound.
Quantitative whole body autoradiography revealed a fast absorption and distribution of the test compound with peak values observed already 1 hour after administration. At this time, the concentrations in liver and kidney were significantly higher than in blood, suggesting a preferred clearance from blood and distribution mainly to these organs which are mainly responsible for metabolism (liver) and excretion (kidney). Higher concentrations than in blood were also detected in the myocardium (heart) and in several glands. Very low levels were found in the brain, spinal cord and renal fat tissue. These results were similar in male and female rats, and independent of the labelling position of the test compound.

Excretion

Excretion was very fast, mainly renal and almost completed after 24 hours. No radioactivity was detected in the expired air after dosing of the pyridinylmethyl- and ethyl-1-labelled compounds, proving the stability of these labelling positions in the molecule. Only after administration of [furanone-4-^{14}C] flupyradifurone between 1% and 3% of the administered radioactivity was exhaled. This demonstrated that for a small portion of the dose (higher in male than in female rats) the furanone ring of the molecule obviously was opened and was subject of biotransformation to C-1 fragments.

A fast decline of radioactivity concentrations was observed for all organs and tissues in male and female rats during the entire test period. Concentrations fell for most organs and tissues below 5% of the maximum concentration after one day. After seven days, only very low concentrations were found in a few organs and tissues of rats dosed with the pyridinylmethyl-labelled test compound. In the study using the furanone-4-labelled compound, low radioactive residues were measured in almost all organs and tissues due to the incorporation of C1- or C2-fragments into the endogenous carbon pool. The residues in male rats were higher by a factor of 1.4 to 4.7 as compared to female rats. A similar ratio of approximately 3 (male/female) was also found for the formation of $^{14}CO_2$, and originates presumably from sex related differences in metabolism leading to more C1- and C2-fragments and also higher incorporation of these components into the endogenous carbon pool in male rats. In general males and female rats exhibited very similar absorption, distribution and excretion behaviour. The results of these studies demonstrate that there is no indication of any accumulation or significant retention of radioactivity in male and female rats. This observation is supported by the low P_{OW} of 1.2. Concentrations of radioactivity detected in tissues and organs at sacrifice were either very low or below the limit of detection

Metabolism

Flupyradifurone was intensively metabolised in the rat. Numerous metabolites were formed, most of them being minor ones. The parent compound represented the predominant part of the radioactivity in urine of male and female rats. In faeces of male rats, the metabolite BYI 02960-OH was more prominent than the parent compound. Two metabolites, BYI 02960-6-CNA and BYI 02960-hippuric acid were also prominent in male but not in females rats. The organ metabolism study using the ethyl-1-^{14}C label showed that in the 24 hours samples of plasma, and organs and tissues BYI 02960-DFA was by far the dominating metabolite accounting for more than 50% of the radioactivity. In general, the metabolic profiles in urine and faeces were very similar for both sexes but male rats showed a higher rate of metabolite formation as compared to female rats. 6-CNA is considered a major metabolite in male rat but not in females.

The principal metabolic reactions of flupyradifurone in rats were:

- Hydroxylation followed by conjugation with glucuronic acid or sulfate,
- cleavage of the difluoroethyl group forming BYI 02960-des-difluoroethyl, and difluoroacetic acid (BYI 02960-DFA),
- cleavage of the molecule at the pyridinylmethylene bridge forming BYI 02960-6-CNA, which was further conjugated with glycine to BYI 02960-hippuric acid and BYI 02960-difluoroethyl-amino-furanone.
- The figure below schematically shows the sites of the molecule, which are involved in the metabolic reactions:

Summarizing, the results of the metabolism studies conducted in the rat, a proposed metabolic pathway of flupyradifurone can be described as shown in this figure:

B.6.11.2 Toxicodynamics

Acute toxicity

Flupyradifurone (BYI 02960) needs to be classified as Acute oral toxic Cat. 4 H302 according to Regulation (EC) 1272/2008. Flupyradifurone does not need to be classified on the basis of its acute dermal, and inhalation toxicology in rats (Category 5/ Unclassified). Flupyradifurone is considered not irritating to skin and eyes (Category 5/ Unclassified). Flupyradifurone does not have sensitising properties in a LLNA (Category 5/ Unclassified).

Table 6.11.2-1 Classification

Type of study	Species	Results	Classification (proposed)
Oral route	Rat	Mortalities observed at 2000 mg/kg; none at 300 mg/kg	Category 4 H302 (LD_{50} cut off >300-2000 mg/kg)
Dermal route	Rat	LD_{50} > 2 000 mg/kg	Category 5 / Unclassified
Inhalation	Rat	LC_{50} at 4 hours > >4.7 mg/L (nose only) ~~4671 mg/m³~~	Category 5 / Unclassified
Primary skin irritation	Rabbit	Non irritating	Category 5 / Unclassified
Eye irritation	Rabbit	Slight redness of the conjunctivae, reversed within 48 hours	Category 5 / Unclassified
Skin sensitization	Mouse	Not sensitizing	Category 5 / Unclassified

Short-term toxicity

Oral

Four subacute oral range-finding studies were performed, with rat, mouse and dog.

In a 28-day study with rats exposed to 0, 75, 200 or 350 mg/kg bw/d via gavage, toxicologically relevant effects were clinical chemical findings, increased organ weights and pathological findings in the 200 mg/kg bw/d group. The NOAEL in this study is set at 75 mg/kg bw/d.

In a 28-day study with rats exposed to 0, 33.6 or 385 mg/kg bw/d via diet, toxicologically relevant effects were clinical chemical findings, increased liver and thyroid weights and associated pathological findings in the 385 mg/kg bw/d group. The NOAEL in this study is set at 33.6 mg/kg bw/d.

In a 28-day study with mouse exposed to 300, 600 and 1200 ppm (equating approximately to 50, 98 and 207 mg/kg bw/day in males and 59, 122, 240 mg/kg bw/day in females) via diet, no toxicologically relevant effects were observed. ~~Given the instability of BYI 02960 in rodent diet the actual concentration is considered to be in the region of 960 to 1080 ppm (166 to 186 mg/kg body weight/day for the males and 192 to 216 mg/kg body weight/day for the females, respectively).~~ The NOAEL in this study is set at 98 ~~166~~ ~~33.6~~ mg/kg bw/d.

In a 28-day study with dogs exposed to 0, 500, 2000 or 4000 ppm (equating approximately to 0, 16, 62, 118 mg/kg body weight/day in males and 0, 18, 77, 131 mg/kg body weight/day in females) via diet, toxicologically relevant effects were body weight loss and reduced body weight gain at the 4000 ppm group. The NOAEL in this study is set at 2000 ppm (62 mg/kg bw/d).

Four semichronic oral studies were performed, with rat, mouse and dog.

In a 90-day toxicity study with rat exposed to 0, 100, 500, 2500 ppm (equating to approximately 0, 6.0, 30.2, 156 mg/kg bw/day in males and 0, 7.6, 38.3, 186 mg/kg bw/day in females) via diet, toxicologically relevant effects were clinical chemical findings, increased relative liver and thyroid weight and associated pathological findings in the 2500 ppm group, and thyroid weight effects in the 500 ppm males. The NOAEL in this study is 100 ~~500~~ ppm (6.0 ~~30.2~~ mg/kg bw/d).

In a 90-day toxicity study with mouse exposed to 0, 100, 500, 2500 ppm (equating approximately to 0, 16, 81, 407 mg/kg bw/day in males and 0, 19, 98, 473 mg/kg bw/day in females) via diet, toxicologically relevant effects were clinical chemical findings, increased relative liver and decreased kidney weights and associated pathological findings in the 2500 ppm group. The NOAEL in this study is 500 ppm (81~~80.6~~ mg/kg bw/d).

In a 90-day toxicity study with dog exposed to 0, 400, 1200 or 3600/2400 ppm (equating approximately to 0, 12, 33 and 102/85 mg/kg bw/ day for males and 0, 12, 41 and 107/78 mg/kg bw/day for females) via diet, toxicologically relevant effects were reduced body weight, reduced body weight gain, clinical chemistry, significant increase in kidney weight and focal myofiber atrophy/degeneration in the 1200 ppm group. The NOAEL in this study is 400 ppm (12 mg/kg bw/d).

In a 1-year toxicity study with dog exposed to 0, 150, 300 and 1000 ppm (equating approximately to 0, 4.6, 7.8 and 28.1 mg/kg bwd/day for males and 0, 4.1, 7.8 and 28.2 mg/kg bw/day for females) via diet, toxicologically relevant effects were micropathology (degeneration of the skeletal muscle (*gastrocnemius* and *biceps femoris* (atrophy, necrosis and/or presence of inflammatory cells)) findings in the 1000 ppm group. The NOAEL in this study is 300 ppm (7.8 mg/kg bw/d).

Dermal

Male and female rats, 10 rats/sex/group (one control and three test substance-dosed groups) were administered BYI 02960 (50, 150, or 500 mg/kg/day) daily by dermal application for at least 28 consecutive days (minimum of 6 h/day) and euthanized one day following the last dose. Based on the lack of adverse findings observed in the study, the 28-day dermal exposure NOAEL in male and female rats dosed with BYI 02960 was 500 mg/kg bw/day.

Genotoxicity

BYI 02960 was not mutagenic in two Ames tests.

BYI 02960 did not induce structural chromosome aberrations in V79 cells when tested up to and including cytotoxic concentrations and showed no mutagenic potency in vitro in the CHO/HPRT assay.

BYI 02960 did not induce micronuclei in mouse bone marrow cells in two separate in vivo studies.

Overall it can be concluded that BYI 02960 has no mutagenic or clastogenic potential.

Long-term toxicity and carcinogenicity

In a two-year toxicity/carcinogenicity study with rats, effects in the liver and in a less extend in the thyroid and lung (females) were observed in the 2000 ppm dose group. The NOAEL for general toxicity was set at 400 ppm in diet, equal to the average daily intake of 15.8 mg/kg bw/d. No neoplastic lesions were observed in the study at any dose level.

In an 18-months carcinogenicity study with mice, effects in the liver and in de kidney (male) were observed in the 1500 ppm dose group. The NOAEL for general toxicity was set at 300 ppm equal to the average daily intake of 45 mg/kg bw/day. The NOAEL for carcinogenicity was set at the highest dose level of 1500 ppm, equal to the average daily intake of 224 and 263 mg/kg bw/day over 18 months for male and female mice, respectively.

Reproductive and developmental toxicity

In the rangefinder one generation rat reproduction study, BYI 02960 was administered continuously in the feed to Wistar rats (10 animals/dose/sex) at nominal dietary concentrations of 0, 200, 700, and 2000 ppm. The parental systemic LOAEL is 700 ppm (60.0 mg/kg bw/day females), based on decreased body weight, decreased body weight gain, alterations in food consumption during premating, and decreased spleen weights in females. The parental systemic NOAEL is 200 ppm (17.5 mg/kg bw/day).

The reproductive NOAEL is 147.5 mg/kg bw/day based on no reproductive findings observed at the highest dose tested.

The offspring LOAEL is 700 ppm (60.9 mg/kg bw/day). The LOAEL is based on maternal effects leading to secondarily-mediated effects on pup weight, pup weight gain, and organ weight changes (brain). The offspring NOAEL is 200 ppm (17.5 mg/kg bw/day).

A significant decrease in body weight, but <10% was observed in the mid-dose of the F1 females and a non significant decrease in body weight gain was found in the parental animals (21 % in females)

and the F1 animals (16 % in females). Therefore the parental systemic LOAEL is considered 500 ppm (32 mg/kg bw/d) based on decreased body weight gain in females. The parental systemic NOAEL is 100 ppm (6.4 ~~7.7~~ mg/kg bw/d). ~~Therefore the parental systemic LOAEL is considered 1800 ppm (117.4 mg BYI 02960/kg bw/day) based on increased liver and thyroid weights, and minimal centrilobular hypertrophy in males decreased body weight (>10%)(premating, gestation, and lactation), body weight gain (premating; P and F_1). The parental systemic NOAEL was 500 ppm (32.0 mg BYI 02960/kg bw/day).~~The reproductive NOAEL was 500 ppm (34.3 mg BYI 02960/kg bw/day females) based on decreased estrous cycle number, litter size, and the number of implants observed in the F_1 generation at the highest dietary level tested (LOAEL = 1800 ppm (134.0 mg BYI 02960/kg bw/day in females).
A significant decrease in body weight, but <10% was observed in the mid-dose of the F2 pups. The offspring LOAEL is therefore 1800 ppm (134.0 mg BYI 02960/kg bw/day) based on maternal effects leading to secondary effects on pup weight, and physical development. The offspring NOAEL is 500 ppm (34.3 mg BYI 02960/kg bw/day).

In a rat developmental study, BYI 02960 was administered daily by gavage to groups of 25 pregnant Sprague-Dawley female rats per dose-group at 15, 50 and 150 mg/kg/day from gestation day (GD) 6 to 20. Minimal maternal toxicity was observed at the high-dose level, manifested as decreased body weight gain and reduced food consumption. The mean absolute liver weight was increased in the high dose group.Based on these findings the Noael vor maternal toxicity was set at 50 mg/kg bw/day. The increased incidence of parietal incomplete ossification showed no dose response, the unossified cervical centrum and the incomplete ossification of the sternebra was within the historical background. A increase of a short costal cartilage was seen at the high-dose. Based on these findings, the NOAEL for developmental toxicity was set at 50 mg/kg bw/day.

In a complementary study, where groups of 23 sperm-positive female Sprague-Dawley rats were exposed to BYI 02960 by oral gavage from gestation day (GD) 6 to 20 at 20 and 30 mg/kg/day, no maternal toxicity was observed up to 30 mg/kg/day. Therefore, based on these two studies, it can be concluded that the NOEL for maternal toxicity was 30 mg/kg/day.

In a rabbit developmental study, groups of 23 time-mated pregnant female New Zealand White rabbits were administered BYI 02960 by oral gavage from gestation day (GD) 6 to 28 at 7.5, 15 and 40 mg/kg/day. The effects on (corrected) body weight gain and food consumption were slight and mainly transient, however considered adverse (>10%).The NOAEL for maternal toxicity and developmental toxicity was set at 15 mg/kg bw/day.~~There were no treatment-related findings for maternal and developmental toxicity therefore the NOAEL for maternal toxicity and developmental toxicity was set at 40 mg/kg bw/day.~~

Neurotoxicity

In an acute neurotoxicity study, BYI 02960 was administered by gavage in a single dose to non-fasted young adult Wistar rats at 0, 50, 200 and 800 mg/kg. Compound-related effects were observed at all dose concentrations in both sexes. The only treatment-related effects at 50 mg/kg were limited to higher incidences of piloerection in both sexes and dilated pupils in females only. A follow-up study was performed in order to establish a clear NOAEL for findings observed at all dose levels in the initial study. In this follow-up study, females only were used as they were equal or more sensitive than males at higher dose levels and were administered BYI 02960 at 20 or 35 mg/kg. No treatment-related effects were evident at either dose tested. The dose level of 35 mg/kg of BYI 02960 was considered to be the overall NOAEL for both sexes.

In a 90-day neurotoxicity study, through approximately 13 weeks of continuous dietary exposure to BYI 02960 at 100, 500 or 2500 ppm, there were no neurotoxic treatment-related findings apparent at any dietary level in either sex. Based on these findings, a NOAEL of 2500 ppm was established for the rat (equating to 143 mg BYI 02960/kg bw/day for males).). Body weight and food intake effects were seen at the highest dosage. The systemic NOAEL is therefore 29.4/34.8 mg/kg bw/d for males and females respectively.

In a developmental neurotoxicity study, dietary exposure to BYI 02960 from GD 6 through LD 21 to mated female Wistar rats resulted in treatment-related effects (maternal: decreased body weight gain. Offspring: decreased body weight gain, slightly increased in motor and locomotor activity, slightly increased auditory startle habituation) evident only at 1200 ppm (102 mg/kg bw/day) in maternal animals and offspring. ~~Therefore, the NOAEL for both maternal animals and offspring is 500 ppm (42.4 mg/kg bw/day) in this developmental neurotoxicity study.~~

The maternal NOAEL was 500 ppm (42.4 mg/kg bw/d) based on decreased body weight and body weight gain. The developmental NOAEL was 500 ppm (42.4 mg/kg bw/d) based on decreased offspring body weight and body weight gain. The developmental neurotoxicity NOAEL was 500 ppm (42.4 mg/kg bw/d) based on increased startle amplitude in females only on PND 60 and increased motor and locomotor activity on PND 13 in males only.

Further toxicological studies

Biokinetic study

Plasma concentration of BYI 02960 was assessed at three time points after continuous dietary administration for seven days. Groups of 5 male and 5 female Wistar rats received the diet admixed with the test substance at a concentration of 400 ppm (equating approximately to 22.6 mg/kg body weight/day in males and 32.4 mg/kg body weight/day in females).

During the first 15 days of acclimatization, the daily light/dark rhythm was 7 a.m. - 7 p.m. Rats being known to preferably eat during the dark period, the daily light/dark rhythm of rats was changed from November 25, 2009 (pre-study Day 16, *i.e.* 14 days prior to first day of treatment) onwards, *i.e.* dark period was from 2 a.m. to 2 p.m. and light period was from 2 p.m. to 2 a.m., in order to allow the blood sampling during the working day. Clinical signs were observed daily. Body weights were measured

just prior to the start of admixed food administration (Study Day 1) and on Study Day 8. Food consumption was recorded on Study Days 1 - 4, 4 - 7 and 7 - 8.
Whole blood was collected on heparin for plasma preparation from treated animals at three time points on Study Day 8 (8 a.m., 2 p.m. and 5 p.m.). The day after the end of the treatment period, animals were sacrificed without necropsy. Dietary administration of BYI 02960 induced no mortalities or treatment-related clinical signs.
The results obtained indicated a small sex difference in the plasma concentrations of BYI 02960, values being slightly higher for females than for males.
In male rats, a Cmax of 8.3 mg/L was measured at the time of collection of 8 a.m. In female rats, a Cmax of 9.4 mg/L was measured at the time collection of 2 p.m. However, in view of the inter-individual variability, the concentrations of BYI 02960 in plasma were considered similar between the three times of blood collection for both sexes (between 7.8 and 8.3 mg/L for males and between 8.8 and 9.4 mg/L for females). In conclusion, in the environmental conditions of the long-term studies (light: 7 a.m. to 7 p.m. & dark period: 7 p.m. to 7 a.m.) and assuming that animals are starting eating food when the light is switched off, the blood collection can be performed between 1 a.m. and 10 a.m. in order to measure the maximum concentration of BYI 02960.

28-Day immunotoxicity study
BYI 02960, was administered continuously via dietary administration to separate groups of female Wistar rats (10/group) at concentrations of 125, 600 and 3000 ppm (equating approximately to 10, 50, 230 mg/kg body weight/day) for at least 28 days. BYI 02960 was considered not to have any immunotoxic potential in female Wistar rats when given in the diet at dose levels up to 3000 ppm (corresponding to approximately 230 mg/kg/day) for at least 28 days.

Toxicity of metabolites
Difluoroacetic acid (DFA, BCS-AA56716) is a major soil, water and plant metabolite of BYI 02960; in the rat ADME study, it was found in urine at around 6% of the administered dose. This metabolite is devoid of genotoxic potential; the acute oral LD50 is between 300 and 2000 mg/kg, similar to parent compound. In a 14 day repeat dietary administration range finding study in the rat, the most significant findings were decreased mean glucose concentration in both sexes and an increase in urea concentration was observed in females only. In a 90-day rat study, DFA was administered in the diet to Wistar rats (10/sex/group) at concentrations of 200, 1000 and 6000 ppm. Lower mean glucose concentrations, lower total bilirubin and slightly higher mean urea concentrations were observed in both sexes at all doses. At 6000 and 1000 ppm dose levels, mean body weight, overall body weight gain and food consumption were reduced in both sexes. Lower hemoglobin concentration and lower mean corpuscular volume were observed in females, together with lower mean corpuscular hemoglobin and lower hematocrit, and higher ketone levels were noted in both sexes. A few black foci were also noted in the glandular part of the stomach in both sexes (including one control female), in correlation with a few cases of focal glandular erosion/necrosis observed at the microscopic examination. The minor changes noted in the clinical chemistry determination at the low dose are

considered not to be adverse effects of the test substance as they do not represent any functional impairment in the test organism. Therefore, the dose level of 200 ppm (equating to 12.7 and 15.6 mg/kg body weight/day in males and females, respectively) was considered to be a No Observed Adverse Effect Level (NOAEL) in the male and female Wistar rats. When the NOAEL is expressed in BYI 02960 equivalents, it equates to 38 and 47 mg/kg/day in males and females, respectively. Therefore, Difluoroacetic acid was not more toxic than BYI 02960 after subchronic administration to the rat. The metabolic changes observed with DFA are also observed with BYI 02960. The decrease in glucose was reversible and appeared to be adaptative as it was no longer significant during the second part of the rat carcinogenicity study.

BYI 02960-difluoroethyl-amino-furanone (BCS-CC98193, BYI 02960-DFEAF) is a minor plant metabolite of BYI 02960 and was also observed in the rat ADME study. It accounted for less than 10% of the administered dose in the rat urine. Since the confined rotational crop study with [furanone-4-14C]BYI 02960 indicated rather high residue levels of BYI 02960-difluoroethyl-amino-furanone in leafy crops and the absence of other suitable markers, BCS decided to include this metabolite in the residue definition for the data collection method for target and rotational crops (see residue section). The subsequent residue studies revealed that BYI 02960-difluoroethyl-amino-furanone is only a minor plant metabolite. However, based on the results of the confined rotational crop study, additional tox studies (acute toxicity testing, genotoxicity testing and subacute rat study) were conducted to show that the tox profile of the metabolite is covered by the endpoints derived from the parent compound. In the *in vitro* genotoxicity package, the Ames and HPRT tests were negative and the chromosome aberration test was positive. Therefore, two *in vivo* studies (*in vivo* micronucleus test and *in vivo* unscheduled DNA synthesis) were conducted, both of which were negative. Based upon the overall findings, BYI 02960-difluoroethyl-amino-furanone can be considered not genotoxic. The acute oral LD_{50} in rats was higher than 2000 mg/kg. The NOAEL of the 28-day rat study was 3000 ppm equating to 243 and 273 mg/kg/day in males and females, respectively based on body weight effects.

Several toxicology studies exist for two plant metabolites BYI 02960-CHMP ((6-chloro-3-pyridyl) methanol) and BYI 02960-6-CAN (6-chloronicotinic acid), which are metabolites common to other pesticides. For BYI 02960-CHMP, the Ames test was negative. The acute oral rat LD_{50} was 1842 mg/kg in males and 1483 mg/kg in females. In a 90-day rat study, BYI 02960-CHMP administered continuously via dietary administration to Sprague Dawley rats (10/sex/group) at concentrations of 160, 800, 4000 and 20 000 ppm resulted in decreases in mean body weights and mean food consumption in both sexes and a statistically significant increases in serum alkaline phosphatase activity in the 20000 ppm group females at study termination only. Histologically, dose-related eosinophilic intranuclear inclusions were seen in the proximal tubular epithelium of kidneys for 20000 ppm males and females and 4000 ppm males. The no observed effects level (NOEL) was 800 ppm (48.9 mg/kg/day) in males, and 4000 ppm (275.9 mg/kg/day) in females. When the NOEL is expressed in BYI 02960 equivalents, it equates to 97.8 and 551.8 mg/kg/day. Therefore, BYI 02960-CHMP was less toxic than BYI 02960 after subchronic administration to the rat.

For BYI 02960-6-CAN (6-chloronicotinic acid) an acute oral rat toxicity study and an Ames test were performed for the registration of acetamiprid. BYI 02960-6-CAN was not genotoxic and not acutely toxic.

The reference values of the parent flupyradifurone are applicable to both metabolites DFA and DFEAF; the experts considered that there was sufficient evidence to conclude that DFEAF is unlikely to have genotoxic potential.

B.6.11.3 ADI

The calculation of the ADI is based on the highest dose at which no adverse effect is observed in the most appropriate study in the most sensitive species. BYI 02960 was tested in several short-term studies in dogs, rats, and mice, in long-term toxicity studies in rats and mice, and in reproduction and developmental toxicity studies in rats and rabbits, providing the basis for the establishment of the ADI. ~~The lowest NOAEL (7.8 mg/kg/day) was obtained from a 1-year study in dog. Similar critical effects (myofiber degeneration, similar number of effected animals) were seen in the 90-day study with dog. It is therefore suggested to use both the 1-year dog study and the 90-day dog study to set the NOAEL of 12 mg/kg/d used as a starting point for the establishment of the ADI, also taking into account the sufficient dose spacing between the 90-day dog NOAEL and the 1-year LOAEL. Application of a safety factor for inter- and intraspecies differences of 100 results in an ADI of 0.12 mg/kg bw/day. The lowest NOAEL (7.7 mg/kg bw/d) was obtained from the 2-generation study in rat based on body weight effects in the parent animals. Application of a safety factor for inter- and intraspecies differences of 100 results in an ADI of 0.08 mg/kg bw/day (rounded from 0.077 mg/kg bw/day).~~

Considering the parental and offspring NOAEL in the multigeneration study, the experts agreed to set the ADI at 0.064 mg/kg bw per day, applying an uncertainty factor of 100.

Table 6.11.3-1 Studies considered for the establishment of the ADI

B.6.11.4 ARfD (acute reference dose)

The calculation of the acute reference dose is based on the highest dose at which no adverse effect is observed in the most appropriate acute toxicity study in the most sensitive species. The maternal NOAEL of 15 mg/kg bw/d in the developmental toxicity study in rabbit is based on a reduced body weight of 12% during the first days of treatment which is an applicable effect to set the ARfD. Application of a safety factor for inter- and intraspecies differences of 100 results in an ARfD of 0.15 mg/kg bw/d.

~~Only slight body weight gain effects were observed at the top dose in the developmental toxicity studies in both rats and rabbits. Acutely toxic effects were seen only in the acute neurotoxixity study, where typical signs of nicotinergic insecticides have been observed. Therefore, it seems appropriate to set up the ARfD using the NOAEL of the acute neurotoxicity study. Application of a safety factor for inter- and intraspecies differences of 100 results in an ARfD of 0.35 mg/kg bw.~~

Table 6.11.4-1 Studies considered for the establishment of the ARfD

Study	NOAEL (mg/kg bw/day)	LOAEL (mg/kg bw/day)	Reference
Reproduction and teratogenicity studies

90-day Neurotoxicity study in the rat - Systemic - Neurotoxicity	 29.4 143	 143 -	[redacted] 2011

B.6.11.5 AOEL

The calculation of the AOEL is based on the highest dose at which no adverse effect is observed in the most appropriate study in the most sensitive species. BYI 02960 was tested in several short-term studies in dogs, rats, and mice, in long-term toxicity studies in rats and mice, in reproduction and developmental toxicity studies in rats and rabbits, and neuro and immuno toxicity studies with rats providing the basis for the establishment of the short-term and long-term AOEL.

The lowest NOAEL (6.4 ~~7.7~~ mg/kg bw/d) was obtained from the 2-generation studie in rat based on body weight effects in the parent animals. A correction factor for oral absorption is not necessary since the oral absorption is >80%. Application of a safety factor for inter- and intraspecies differences of 100 results in an ADI of 0.08 mg/kg bw/day (rounded from 0.077 mg/kg bw/day).

~~The lowest NOAEL (7.8 mg/kg/day) was obtained from a 1-year study in dog. Similar critical effects (myofiber degeneration, similar number of effected animals) were seen in the 90-day study with dog. It is therefore suggested to use both the 1-year dog study and the 90-day dog study to set the NOAEL of 12 mg/kg/d used as a starting point for the establishment of the AOEL, also taking into account the sufficient dose spacing between the 90-day dog NOAEL and the 1-year LOAEL. A correction factor for oral absorption is not necessary since the oral absorption is >80%. Application of a safety factor for inter- and intraspecies differences of 100 results in an AOEL of 0.12 mg/kg bw/day for both short-therm and long-therm.~~

B.6.11.6 Drinking water limit

According to Council Directive 97/57/EC, exposure to BYI 02960 through drinking water should account for not more than 10% of the ADI. If it is assumed that the average daily consumption of water amounts to 2 litre per person of 60 kilogram, a potential drinking water limit of ((60x0.064 ~~0.08~~ ~~0.12~~)/10)/2 mg/l, i.e.0.192 ~~0.24~~ ~~0.36~~ mg/l can be established.

According to Document 8064/VI/79 of the European Commission, the EU drinking water limit for pesticides of 0.1 µg/l is applicable for BYI 02960.

B.6.12 ACUTE TOXICITY INCLUDING SKIN SENSITISATION OF PREPARATIONS (ANNEX IIIA 7.1)

B.6.12.1 Acute toxicity

STUDY 1

Characteristics

reference	:	[redacted]. 2010	exposure	:	gavage
type of study	:	Acute oral toxicity study	doses	:	2000 mg/kg bw
year of execution	:	2010	vehicle	:	Tap water
test substance	:	BYI 02960 SL 200 g/L (batch 2009-001253)	GLP statement	:	yes
route	:	oral	guideline	:	OECD 423
species	:	Rat, Wistar HsdCpb:Wu	acceptability	:	Acceptable
group size	:	3 females/step	**LD50**	:	>2000 mg/kg bw

Study design

The study was performed in accordance with OECD 423.

Groups of three female Wistar rat per step were orally exposed to BYI 02960 SL 200 g/L at a concentration of 2000 mg/kg bw. The test item was formulated in tap water with an administration volume of 10 ml/kg bw. Clinical signs and mortality rates were determined several times on the day of administration and subsequently at least once daily for an observation period of at least 14 days. The

weight gain of the animals was checked weekly. At the end of the study the animals were sacrificed, dissected and examined macroscopically.

Results

Mortality: No mortality was observed.

Symptoms of toxicity: Clinical signs consisted of decreased motility and temporary tremor.

Body weight: Body weight increased throughout the study period.

Pathology: No macroscopic pathologic abnormalities were observed

Acceptability

This study is considered acceptable.

Conclusion

The LD50 values of the formulation BYI 02960 SL 200 g/L was found to be greater than 2000 mg/kg bw.

STUDY 2

Characteristics

reference	:	[redacted]. 2010	exposure	:	24 hours on a 10% skin area (semi-occlusive)
type of study	:	Acute dermal toxicity	doses	:	2000 mg/kg bw
year of execution	:	2010	vehicle	:	None
test substance	:	BYI 02960 SL 200 g/L (batch 2009-001253)	GLP statement	:	yes
route	:	percutaneous	guideline	:	OECD 402
species	:	Rat, Wistar	acceptability	:	Acceptable
group size	:	5/sex	**LD_{50}**	:	>2000 mg/kg bw

Study design

The study was performed in accordance with OECD 402.

Groups of five male and five female Wistar rats received a single dermal dose of 2000 mg/kg bw of BYI 02960 SL 200 g/L (batch 2009-001253). The required amount of the pure liquid test substance was applied to an approximately 10% body surface area under semi-occlusive dressing for 24 hours. After 24 hours the dressings were removed and the area was rinsed. Clinical signs and mortality rates were determined several times on the day of application and subsequently at least once daily for an observation period for an observation period of at least 14 days. The weight gain of the animals was checked weekly until the end of the study.

Results

Mortality: No mortality was observed

Symptoms of toxicity: No treatment related findings were observed

Body weight: The mean body weights increased throughout the study period.

Pathology: No macroscopic pathologic abnormalities were observed.

Acceptability

The study is considered acceptable.

Conclusions

The acute dermal LD50 of BYI 02960 SL 200 g/L in male and female rats was found to be greater than 2000 mg/kg bw.

STUDY 3

Characteristics

reference	:	[redacted] 2010	exposure	:	4 hours; nose-only
type of study	:	Acute inhalation toxicity	doses	:	Nominal concentration 4236.1 and 9613.9 mg/m^3 Actual concentration: 1956.6 and 4483.0 mg/m^3 (MMAD 1.66-1.97 µm, GSD 1.69-1.78)
year of execution	:	2010	vehicle	:	none
test substance	:	BYI 02960 SL 200 g/L (batch 2009-001253)	GLP statement	:	yes
route	:	inhalation	guideline	:	OECD 403
species	:	Rat, Wistar HsD Cpb: Wu (SPF)	acceptability	:	Acceptable
group size	:	5/sex/dose	**LC_{50}**	:	3496 mg/m^3

Study design

The study was performed in accordance with OECD 403 (1981).

Groups of five male and female Wistar rats were nose-only exposed to BYI 02960 SL 200 g/L (batch 2009-001253) for 4 hours at a mean aerosol concentration of 1956.6 and 4483.0 mg/m^3. Body weights were measured before exposure, on day 1, 3, 7 and weekly thereafter. Clinical signs and mortality were examined several times on the day of exposure and at least once daily thereafter for a period of 14 days. At the end of the study period the surviving rats were sacrificed and were given a gross-pathological examination.

Results

Table 6.12.1-1 Mortality:

Mean aerosol concentration (mg/m^3)	Mortality	
	Males	Females
1956.6	0/5	0/5
4483.0	2/5	4/5

Symptoms of toxicity: In surviving animals in both doses clinical signs included, bradypnea, laboured breathing patterns, irregular breathing, piloerection, cyanosis, reduced motility, limp, gait high legged,

nasal discharge serous, nose with red encrustations, nose and muzzle with red encrustations, nostrils with red encrustations and hypothermia. On day 8 post exposure all rats were without clinical signs. In 4483.0 mg/m^3 exposed animals reflex measurements revealed reduced tonus and grip strength as well as an impaired righting response.

Body weight: In high dose males significantly reduced body weight compared to control.

Pathology: In surviving animals discoloration of the lung and/or kidney was observed. The rats that died showed findings such as a less collapsed lung, dark-red discoloration of the lung and a trachea filled with foamy viscous content. These finding were suggestive to lung oedema as cause of death. In addition light discoloration of the spleen, discoloration of the liver, reddish mucous content in the intestines were observed.

Acceptability

The study is considered acceptable.

Conclusion

LC50 value females 3496 mg/m^3, LC50 males > 4483 mg/m^3

B.6.12.2 Irritation and sensitisation

STUDY 1

Characteristics

reference	:	[redacted] 2010	exposure	:	4-hours semi-occlusive
type of study	:	Skin irritation study	doses	:	0.5 ml
year of execution	:	2010	vehicle	:	none
test substance	:	BYI 02960 SL 200 g/L (batch 2009-001253)	GLP statement	:	yes
route	:	dermal	guideline	:	OECD 404
species	:	Rabbits Crl:KBL(NZW)BR	acceptability	:	Acceptable
group size	:	Three females	**Effect**	:	Not skin irritating

Study design

The study was performed in accordance with OECD 404 (2002).

Three female New-Zealand white rabbits (Crl:KBL(NZW)BR) were dermally exposed to 0.5 ml of BYI 02960 SL 200 (batch 2009-001253) on a skin area of 2.5 x 2.5 cm^2 under semi-occlusive dressing. After 4 hours of exposure the patch was removed and the exposed area was washed with water. The dermal irritation was scored at approximately 1, 24, 48 and 72 hours after patch removal.

Results

The results are summarised below.

Table 6.12.2-1 Individual irritation scores

Scores observed after	1 hour	24 hours	48 hours	72 hours
Erythema	0/0/0	0/0/0	0/0/0	0/0/0
Oedema	0/0/0	0/0/0	0/0/0	0/0/0

Animal	mean 24-72 hrs	
	erythema	oedema
1	0	0
2	0	0
3	0	0
mean	0	0

Acceptability

The study is considered acceptable.

Conclusion

The formulation BYI 02960 SL 200 is considering not irritating to skin.

STUDY 2

Characteristics

reference	:	[redacted]. 2010b	exposure	:	1 hour
type of study	:	Eye irritation	doses	:	0.1 ml
year of execution	:	2010	vehicle	:	none
test substance	:	BYI 02960 SL 200 g/L (batch 2009-001253)	GLP statement	:	yes
route	:	Ocular	guideline	:	OECD 405
species	:	Rabbits (Crl:KBL(NZW)BR)	acceptability	:	yes
group size	:	Three females	**Effect**	:	Not eye irritant

Study design

The study was performed in accordance with OECD 405 (2002).

Three female albino rabbits (Crl:KBL(NZW)BR) received 0.1 ml of BYI 02960 (batch 2009-001253) into the conjunctival sac of one eye. The lids were gently held together for about one second in order to prevent loss of the test compound. The eye, which remained untreated, served as control. The eye was rinsed approximately 24 hours following instillation. Eye irritations were scored and recorded approximately at 1, 24, 48 and 72 hours post application.

Results

The results are summarised below.

Table 6.12.2-3 Individual irritation scores

Scores observed after	1 hour	24 hours	48 hours	72 hours
Cornea/opacity	0/0/0	0/0/0	0/0/0	0/0/0
Iris	0/0/0	0/0/0	0/0/0	0/0/0
Conjunctiva redness	1/1/1	1/1/2	1/1/2	0/0/0
Conjunctiva chemosis	0/0/0	0/0/0	0/0/0	0/0/0

B.6.12.2.2 Table 6.12.2-4 Mean value irritation scores

Animal	mean 24-72 hrs			
	Corneal opacity	Iris	Conjunctiva redness	Conjunctiva chemosis
1	0	0	0.7	0
2	0	0	0.7	0
3	0	0	1.3	0
mean	0	0	0.9	0

Acceptability

The study is considered acceptable.

Conclusions

BYI 02960 is considered not irritating to eyes.

STUDY 3

Characteristics

reference	:	[redacted]. 2010	exposure	:	Epicutaneous, three consecutive days.
type of study	:	Skin sensitisation (LLNA)	doses	:	0, 25, 50,100%
year of execution	:	2010	vehicle	:	1% Pluronix Acid L92
test substance	:	BYI 02960 SL 200 g/L (batch 2009-001253)	GLP statement	:	yes
route	:	dermal	guideline	:	OECD 429
species	:	Mice, CBA/J	acceptability	:	yes
group size	:	5 females/group	**Effect**	:	Skin sensitising

Study design

The study was carried out according to OECD guideline 429. With the deviation that one animal of the control group and one animal at a concentration of 25% did not receive the injection of tritiated thymidine due to technical problems.

BYI 02960 SL 200 g/l (batch 2009-001253) was applied on the external surfaces of each ear (25 µl/ear) of groups of five female CBA/J mice for three consecutive days. On day 5, the cell proliferation

in the draining auricular lymph nodes was measured by incorporation of tritiated thymidine and the obtained values were used to calculate proliferation indices. The positive control group received 30% alpha-Hexylcinnamaldehyde (HCA).

Results

No mortality, signs of systemic toxicity or effects on body weight were observed. No cutaneous reactions were observed at the treated site.

Table 6.12.2-5 Stimulation index

Treatment	Cell count Stimulation Index
Vehicle	-
25%	1.3
50%	2.3
100%	3.0
HCA	6.4

Acceptability

The study is considered acceptable.

Conclusions

The formulation BYI 02960 SL 200 g/L was found to be sensitizing in the Local Lymph Node Assay at concentration of 100% (SI ≥ 3.0). According to EC classification criteria (2001/59/EC Directive), the formulation is labelled as R43, may cause sensitization by skin contact.

B.6.12.3 Summary

The results of the acute toxicity, irritation and sensitisation studies are presented in table 6.12.3-1, 6.12.3-2 and 6.12.3-3, respectively.

Table 6.12.3-1 Acute toxicity, LD_{50}/LC_{50} values

Test substance	LD_{50}/LC_{50}	Species	Route	Vehicle	Reference
BYI 02960 SL 200 g/L	>2000 mg/kg bw	Rat	Oral	Tap water	[redacted] 2012
BYI 02960 SL 200 g/L	>2000 mg/kg bw	Rat	Dermal	None	[redacted]. 2010
BYI 02960 SL 200 g/L	3496 mg/m^3	Rat	Inhalation	None	[redacted] 2010

Table 6.12.3-2 Skin and eye irritation studies

Test substance	Effect/Classification	Species	Route	Vehicle	Reference
BYI 02960 SL 200 g/L	Not skin irritating	Rabbit	Dermal	None	[redacted] 2010
BYI 02960 SL 200 g/L	Not eye irritating	Rabbit	Occular	None	[redacted] 2010b

Table 6.12.3-3 Sensitisation studies

Test substance	Effect/Classification	Species	Route	Vehicle	Reference
BYI 02960 SL 200 g/L	Skin sensitising (LLNA)	Mouse	Dermal	1% Pluronix Acid L92	[redacted] 2010

The formulation BYI 02960 SL 200 g/L does not need to be classified on the basis of its acute oral, dermal toxicology. According to the EC classification criteria (Directive 2001/59/EC) formulation BYI 02960 SL 200 g/L is classified with R20, Harmful by inhalation. BYI 02960 SL 200 g/L is considered not irritating to skin and eyes. BYI 02960 SL 200 g/L has sensitising properties in a LLNA and is classified with R43, may cause sensitization by skin contact.

B.6.13 DERMAL ABSORPTION (ANNEX IIIA 7.3)

B.6.13.1 Dermal absorption, *in vitro*

STUDY 1

Characteristics

reference	:	Odin-Feurtet, M. 2010	exposure	:	8 hours, unoccluded
type of study	:	*In vitro* rat and human dermal absorption study.	doses	:	200 g/L, 0.625 g/L and 0.1 g/L
year of execution	:	2010	vehicle	:	blank formulation BYI 02960 SL200
test substance	:	BYI 02960 Radiolabelled: [^{14}C]-BYI 02960, purity 99%, specific activity 4.37 MBq/mg Non-labelled: BYI 02960, purity 99.4%	GLP statement	:	yes
route	:	dermal	guideline	:	OECD 428
species	:	Human skin and rat (Wistar Rj: WI (IOPS HAN)) skin	acceptability	:	acceptable
group size	:	6/dose	**Result**	:	Human: 0.20%, 2.0%, 4.8% in high/mid/low dose Rat: 0.15%, 5.7%, 6.6% in high/mid/low dose

Study design

The *in vitro* percutaneous absorption of [^{14}C]-BYI02960 formulated as an SL200 formulation was studied following a single 8-hour application at three dose levels in excised human and rat skin. Three dose levels were used, the neat product (200 g BYI 02960/L formulation) and two spray dilutions (0.625 g BYI 02960/L formulation and a 0.1 g BYI 02960/L formulation). Due to high inter-individual variability in the groups of skin rat exposed to the low dose an additional six skin membranes were exposed to the low dose.

Dermatomed skin membranes were maintained in flow-through cells at approximately 32°C. The three liquid formulations were applied at a rate of 10 µL/cm2 to unoccluded skin samples mounted in flow-through diffusion cells. Receptor fluid samples were collected at hourly intervals during 24 hours. Eight hours post-application, the remaining dose material was washed off the skin with freshly prepared 1% v/v Tween 80 in PBS (phosphate buffered saline) using natural sponge swabs. At the end of the study (24 hours) the skin samples were swabbed again and were tape-stripped to remove residual surface dose and the stratum corneum. Tape strips were analyzed individually and the first two tape strips were considered non-absorbed. The skin samples were removed from the diffusion cells and taken for analysis.

Results

Some of the cells had to be excluded from analysis for the following reasons; technical problems at swabbing (R12, H15 and R19), high inter-individual variability in the groups of skin rat exposed to the low dose formulation (R13 to R18), different direct absorption compared to other cells in the group (H09, R08). The full results from the outliers were not included in the study.

Following a single application of BYI 02960 the total recovery ranged between 96.2% to 106.1%. High variability was observed in the skin compartment of up to 123% of the mean total % at dose site. At the high dose level, the mean total potentially absorbed dose was 0.20% and 0.15% of the applied dose for human skin and rat skin, respectively. Following application at the intermediate dose dermal absorption was 2.0 and 5.67% for human and rat skin, respectively. At the low dose 4.75% and 6.61% was potentially absorbed for human and rat skin, respectively.

Acceptability

The study is considered acceptable.

Conclusion

At the low dose dermal absorption was 4.8% for human skin and 6.6% for rat skin. In the mid dose 2.0% of the applied dose was absorbed in human skin and 5.7% in rat skin. For the neat formulation 0.20% of the applied dose was potentially absorbed for human skin and 0.15% for rat skin.

Study design

The study was conducted according to the OECD Guideline for the Testing of Chemicals, 427.

The percutaneous absorption of [^{14}C]-BYI02960 formulated as an SL200 formulation was studied following a single 8-hour application at three dose levels in male Wistar rats. The exposure levels were: the neat formulation containing 200 g BYI 02960/L, 0.625 g BYI 02960/L (1:320 dilution) and 0.1 g BYI 02960/L (1:2000 dilution). After dose application, the skin was semi-occluded with a perforated plastic cover held in place with surgical tape. Following the 8-hour exposure period, the remaining dose was washed off the skin with 1% v/v Tween 80 in phosphate buffered saline using sponge swabs. The swabs were retained for analysis. Group of four rats at each dose level was sacrificed at 8, 24, 72 and 168 hours post-application. Urine and faeces were collected separately into receivers at 0 to 8, 8 to 24 and at 24-hour intervals up to sacrifice. A tape stripping procedure was included in order to determine the distribution of the radioactivity through the skin. The following specimens were examined for residual radioactivity; urine, cage wash, faeces, whole blood, skin swabs, stratum corneum, tape strips, skin, surrounding skin, carcass.

Results

There were no treatment related clinical signs observed during the study.

<u>High dose</u>

After a single application of BYI 02960 SL200 at 200 g/L, the mean recovery rates were 113.4%, 102.4% 101.7% and 101.1% for the 8, 24, 72 and 168 hours groups, respectively. Total absorbed dose (skin compartment + systemic compartment) ranged between 17.0% to 21.8%.

Table 6.13.2-1: The mean distribution of radioactivity 8, 24, 72 and 168 hours after a single topical application of [14C]-BYI 02960 from a 200 g/L SL 200 formulation

Acceptability

The study is considered acceptable.

Conclusion

The amount of applied radiolabelled [14C]-BYI 02960 which can be considered as the maximum percentage that could be considered as potentially absorbable under the experimental conditions of this study was 21.8%, 9.7% and 20.6% for the high, intermediate and low dose formulations respectively.

B.6.13.3 Overall conclusion comparative dermal absorption

Table 6.13.3-1: Derivation of human dermal absorption of BYI 02960 from *in vivo* and *in vitro* dermal absorption data.

	Dermal absorption % of applied dose		
Test system	**Concentrate (200 g/L)**	**Intermediate (0.625 g/L)**	**Low (0.1 g/L)**
In vivo rat	21.8	9.7	20.6
In vitro rat	0.2	5.7	6.6
In vitro human	0.2	2.0	4.8
Ratio *in vitro* human / rat	1	0.35	0.73
Corrected human skin penetration	**22**	**3**	**15**

The predicted human dermal absorption value based on the *in vivo* data in rats corrected for the ratio of absorption between rats in humans *in vitro* is higher than the human *in vitro* data alone. The EFSA guidance on dermal absorption (EFSA Journal 2012; 10(4): 2655) states that in these cases it is justified to take the lower value from human *in vitro* data as rat data generally overpredict dermal absorption.

The dermal absorption for BYI02960 200SL in the human *in vitro* study was 0.20% (±0.22) for the concentrate and 2.0% (±1.07) and 4.75% (±2.96) for the intermediate dose (0.625 g/L) and low dose (0.1 g/L), respectively. There was significant variation between replicates with the standard deviation up to 110% of the mean absorption value. The EFSA guidance on dermal absorption recommends that if the variation between replicates is equal to or larger than 25% of the mean absorption consideration should be given to using a value other than the mean. The preferred method is the addition of a standard deviation to the mean values. This leads to a dermal absorption values for risk assessment of 0.4% for the concentrate, 3% for the intermediate dose (0.625 g/L) and 8% for the low dose of 0.1 g/L.

B.6.14 TOXICOLOGICAL DATA ON NON ACTIVE SUBSTANCES (ANNEX IIIA 7.4 AND POINT 4 OF THE INTRODUCTION)

MSDSs for the ingredients of BYI02960 200SL were submitted by the notifier.

Considering human toxicological endpoints (endpoints for which the formulation was tested are excluded):
None of the co-formulants is labelled.

B.6.15 DISLOGEABLE FOLIAR RESIDUES

Study 1

Characteristics

Reference	:	Freitag, T & Suke, S 2011	Application rate	:	2x 0.125 kg as/ha
Type of study	:	Dislogeable foliar residue study	Area	:	Northern Europe (Netherlands)
Year of execution	:	2010-2011	Plant	:	Lettuce
Test substance	:	BYI 02960 SL 200 G (Soluble liquid) 196.3 g/L flupyradifurone. (Batch no. 2010-000672)	Sampling	:	leaves
GLP statement	:	yes	Analysis	:	HPLC-MS/MS
Guideline	:	US EPA OPPTS 875.2100	Acceptability	:	Acceptable

Material and methods

The purpose of the study was to determine the magnitude of the dislodgeable foliar residues of flupyradifurone on lettuce leaf foliage after each of two spraying applications with BYI 02960 SL 200 (200 g flupyradifurone/L). The study was conducted in Northern Europe (The Netherlands) during the 2010 season. The actual application data are presented in the following table.

Table 6.15.1-1: Application parameters

Country	Application				
	Type	Number	Interval (days)	Growth stage (BBCH)	Rate (kg a.s./ha)
The Netherlands	Spraying	2	10	45 - 48	0.125

Samples were collected in a manner designed to obtain representative samples. They were taken, prepared in the field where necessary, transported and stored. Leaf punches were collected directly into a pre-labelled poly-propylene jar using a leaf punch sampler (Birkestrand Co; El Monte, CA). Each sample consisted of 40 disks cut with a leaf puncher with 2.523 cm diameter and a disk area of 5 cm^2. The leaf punches represented a total double-sided leaf surface area of 400 cm^2. A sample was collected from each of the three subplots to provide three replicate samplings at each sampling interval. Leaf punches were taken from the potential worker contact zone including upper, middle, and lower portions of the crop foliage and interior and exterior portions of the crop foliage. Control leaf punch samples were collected prior to the first application. Treated samples collected on the day of

application were taken after the spray had dried. After each sample was collected, the sampling jar was capped and kept cool for transport to the field site laboratory. Leaf punch samplers were cleaned after each sampling interval. The dislodging of the leaf samples was performed as soon as possible, but not later than 4 hours after collection. The samples were dislodged using a 0.01% Aerosol OT solution (i.e. docusate sodium salt which corresponds to a surfactant), and analysed by HPLC-MS/MS.

Results and discussion

The results are summarised in the following table.

Table 6.15.1-2: Amounts of dislodgeable foliar flupyradifurone residues on lettuce in the Netherlands [µg a.s./cm^2], two sided. Figures in bold indicate day of treatment

Sampling [DA1.T][#]	Dislodgeable foliar residues [µg a.s./cm^2]
-0	<0.01
0	**0.291**
3	<0.01
5	<0.01
7	<0.01
-10	<0.01
10	**<0.01***
11	<0.01
13	<0.01
15	<0.01
17	<0.01
20	<0.01

[#]:DA1.T: day after first treatment; " - " = before respective treatment; * for explanation see text

Already immediately after the treatment there is a clear decline of dislodgeable foliar residues, resulting in values <LOQ. The second application – 10 days after the first one – was performed as no rain was expected. However, 20 minutes after the application there was rainfall for about 20 minutes with one minute of hard rain. Obviously this has washed off any residues from the leaf surfaces.

Field fortification samples and lab fortification samples were spiked with 0.01, 0.1 and 1.0 µg/cm^2. The recovery values are presented below.

Table 6.15.1-3: Laboratory recovery data for flupyradifurone

Sample material	FL [µg/cm^2]	Single Values [%]	Mean Value	RSD [%]	LOQ [µg/cm^2]
Lettuce, leaf punch washings	0.01	88; 90; 92; 88; 92; 93	91	2.4	0.01
	0.10	91; 101; 94; 95; 114; 95	98	8.5	

1.0	94; 94; 92; 91; 97; 93	94	2.2
	Overall Recovery (n=18)	94	6.2

FL = Fortification Level, RSD = Relative Standard Deviation, LOQ = Practical Limit of Quantification
These recoveries were performed during the conduct of the DFR study.

Table6.15.1-4: Field Recovery data for flupyradifurone

Sample material	FL [µg/cm²]	Single Values [%]	Mean Value	RSD [%]	LOQ [µg/cm²]
Lettuce, leaf punch washings	0.01	69; 77; 66	71	8.0	0.01
	0.10	76; 66; 96	79	19.3	
	1.0	64; 56; 82	67	19.8	
		Overall Recovery (n=9)	72	16.3	

FL = Fortification Level, RSD = Relative Standard Deviation,
LOQ/D = Practical Limit of Quantification/Detection

The laboratory and procedural recoveries are within the acceptable range (70-110%, See Guidance for generating and reporting methods of analysis in support of pre-registration data requirements…(SANCO/3029/99 rev. 4) for 0.01 and 0.10 µg/cm². The field recovery for 1.0 µg/cm² is only 67%, however since the foliar dislogeable residues are maximally 0.291 µg/cm² the study is considered acceptable.

Conclusion

The DFR value at day 0 (i.e. shortly after application when the spray has dried) amounts to 0.29 µg/cm². This corresponds to 2.3 µg a.s./cm² per kg a.s./ha. Already three days after application the DFR is <LOQ (0.01 µg/cm²).

Due to the heavy rain shortly after the second application no results are available from this application. However, as the DFR values before the second application were already constantly <LOQ no other figures than the ones from the first application would have been expected for the second application: Three days after application the DFR values are <LOQ.

<u>Study 2</u>

Characteristics

Reference	:	Freitag, T. & Suke, S 2011	Application rate	:	2x 0.125 kg as/ha
Type of study	:	Dislogeable foliar residue study	Area	:	Southern Europe (Portugal)
Year of execution	:	2010-2011	Plant	:	Lettuce

After each treatment, there is an immediate decline of dislodgeable foliar residues resulting in values <LOQ, already 3 days after application.

Field fortification samples and lab fortification samples were spiked with 0.01, 0.1 and 1.0 µg/cm^2. The field recovery values are presented below (for the lab fortification samples see Study 1).

Table 6.15.1-7: Field recovery data for flupyradifurone

Sample material	FL [µg/cm^2]	Single Values [%]	Mean Value	RSD [%]	LOQ [µg/cm^2]
Lettuce, leaf punch washings	0.01	72; 87, 57	72	15	0.01
	0.10	79; 96; 89	88	9.7	
	1.0	97; 52; 69	72	23	
		Overall Recovery (n=9)	78	16	

FL = Fortification Level, RSD = Relative Standard Deviation,
LOQ/D = Practical Limit of Quantification/Detection

The laboratory and procedural recoveries are within the acceptable range (70-110%). The study report noted that the values 57 and 52% were unexpected low results and are probably due to inhomogenous sample solution in the used tubes.

Conclusion

The DFR value at day 0 (i.e. shortly after application when the spray has dried) amounts to 0.11 µg/cm². The second application results in a significant higher figure while the samples before the second application were already constantly <LOQ. Hence, there is no indication that residues from a former application could have accumulated. Most likely, there was just a lower target deposition at the first application.

The value of the second application (= 0.26 µg/cm²) corresponds to 2.1 µg a.s./cm^2 per kg a.s./ha, within three days after application the DFR values are <LOQ.

<u>Study 3 Foliar dislogeable residues</u>

Characteristics

Reference	:	Freitag, T. & Suke, S 2011	Application rate	:	2x 0.125 kg as/ha (1N for lettuce, 0.83N for hops)
Type of study	:	Dislogeable foliar residue study	Area	:	Greenhouse (The Netherlands)
Year of execution	:	2010-2011	Plant	:	Lettuce
Test substance	:	BYI 02960 SL 200 G (Soluble	Sampling	:	leaves

		liquid) 196.3 g/L flupyradifurone. (Batch no. 2010-000672)			
GLP statement	:	yes	Analysis	:	HPLC-MS/MS
Guideline	:	US EPA OPPTS 875.2100	Acceptability	:	Acceptable

Material and methodslettertype en grootte

The purpose of the study was to determine the magnitude of the dislodgeable foliar residues of flupyradifurone on lettuce leaf foliage after each of two spraying applications with BYI 02960 SL 200 (200 g flupyradifurone/L). The study was conducted in Northern Europe (The Netherlands) in the greenhouse during the 2010 season. The actual application data are presented in the following table.

Table 6.15.1-8: Application parameters

Country	Application				
	Type	Number of applications	Interval (days)	Growth stage (BBCH)	Rate (kg a.s./ha)
The Netherlands	Spraying	2	10	44 - 48	0.125

Samples were collected in a manner designed to obtain representative samples. They were taken, prepared in the field where necessary, transported and stored according to US EPA OPPTS 875.2100 Foliar Dislodgeable Residue Dissipation. Leaf punches were collected directly into a pre-labelled poly-propylene jar using a leaf punch sampler (Birkestrand Co; El Monte, CA). Each sample consisted of 40 disks cut with a leaf puncher with 2.523 cm diameter and a disk area of 5 cm^2. The leaf punches represented a total double-sided leaf surface area of 400 cm^2. A sample was collected from each of the three subplots to provide three replicate samplings at each sampling interval. Leaf punches were taken from the potential worker contact zone including upper, middle, and lower portions of the crop foliage and interior and exterior portions of the crop foliage. Control leaf punch samples were collected prior to the first application. Treated samples collected on the day of application were taken after the spray had dried. After each sample was collected, the sampling jar was capped and kept cool for transport to the field site laboratory. Leaf punch samplers were cleaned after each sampling interval. The dislodging of the leaf samples was performed as soon as possible, but not later than 4 hours after collection. The samples were dislodged using a 0.01% Aerosol OT solution (i.e. docusate sodium salt which corresponds to a surfactant) and analysed by HPLC-MS/MS.

Results and discussion

The results are summarised in the following table.

Table 6.15.1-9: Amounts of dislodgeable foliar flupyradifurone **residues on lettuce in the Netherlands [µg a.s./cm^2], two sided. Figures in bold indicate day of treatment**

Sampling [DA1.T][#]	Dislodgeable foliar residues [µg a.s./cm^2]
-0	<0.01
0	**0.293**
3	0.010
5	<0.01
7	<0.01
-10	<0.01
10	**0.316**
11	0.235
13	0.010
15	<0.01
17	<0.01
20	<0.01

[#]:DA1.T: day after first treatment; " - " = before respective treatment

After each treatment there is an immediate decline of dislodgeable foliar residues resulting in values at the LOQ already 3 days after application.

Field fortification samples and lab fortification samples were spiked with 0.01, 0.1 and 1.0 µg/cm^2. The field recovery values are presented below (for the lab fortification samples see Study 1).

Table 6.15.1-10: Field Recovery data for flupyradifurone

Sample material	FL [µg/cm^2]	Single Values [%]	Mean Value	RSD [%]	LOQ [µg/cm^2]
Lettuce, leaf punch washings	0.01	77; 78; 82	79	3.3	0.01
	0.10	82; 92; 81	85	7.2	
	1.0	1*; 87; 78	83	-	
		Overall Recovery (n=8)	82	6.2	

FL = Fortification Level, RSD = Relative Standard Deviation,
LOQ/D = Practical Limit of Quantification/Detection
*Unexpected low result. Either a wrong spiking solution was sent to the field or a mistake during the field phase occurred. This value is not considered.

The laboratory and procedural recoveries are within the acceptable range (70-110%).

Conclusion

The DFR value at day 0 (i.e. shortly after application when the spray has dried) amounts to 0.29 µg/cm². This corresponds to 2.3 µg a.s./cm^2 per kg a.s./ha. Then an immediate decline quickly leads to values <LOQ. The DFR value at day 10 – just after the second application when the spray

has dried – amounts to 0.32 µg/cm², corresponding to 2.5 µg a.s./cm² per kg a.s./ha. Again, three days after application the DFR values are at the LOQ.
On average, the DFR_0-values amount to 2.4 µg a.s./cm² per kg a.s./ha.

B.6.15.1 Overall conclusion on DFR

The DFR_0-values amount to similar values for field application in the Netherlands or Portugal or greenhouse applications in the Netherlands (respectively 2.3; 2.1 and 2.4 µg a.s./cm² per kg a.s./ha). Therefore, a DFR_0-value of 2.4 µg a.s./cm² per kg a.s./ha can be used in the human risk assessment.

B.6.16 EXPOSURE DATA (ANNEX IIIA 7.2)

Product information

Product	:	Sivanto
Purpose	:	Insecticide
Active substance (a.s.)	:	Flupyradifurone (BYI 02960) 200 g/L
Product type	:	Soluble liquid formulation SL
Package size	:	0.25, 0.5, 1, 3, 5 and 10 liter bottle (36-50-63 mm screw cap)

Internal operator exposure values without and with personal protective equipment (PPE) were calculated using the UK and the German model. For risk assessment purposes, the 75th percentile of the UK-model was used (UK-75th) and the geometric mean of the German model (DE-GM). For the greenhouse application, internal operator exposure values without and with PPE were calculated using the Dutch model. For risk assessment purposes, the 90th percentile of the Dutch model (NL-90th) was used.

For bystander exposure during manual or mechanical spraying outdoors, no formally approved models exist. As an estimate, the draft values proposed for the EUROPOEM II, 2002 model were used. These values represent the 90th percentile exposure values for bystanders. Since bystanding should as much as possible be prevented and will usually occur incidentally, it cannot be assumed that bystanders will be using any kind of personal protective equipment, therefore the use of this equipment is not considered in bystander risk assessment.
In greenhouses, no bystander exposure during application is considered, as Good Agricultural Practice requires absence of bystanders.

For worker exposure no formally approved models exist. As an estimate, the draft values proposed for the EUROPOEM II, 2002 model were used. These values represent the 90th percentile exposure values for workers.

For operator, worker and bystander risk assessment the semi-chronic systemic AOEL was used (see section B.6.10.5).
According to the GAP, the maximal dilution is 0.045 g/L. This is lower than the dose tested in the derma absorption studies (0.1 g/L), hence the value of the studies needs to be corrected. The *in vitro* human data also needed to be corrected for the large standard deviation (4.75% + 2.96% as described in section B.6.13.2). This results in a dermal absorption of (4.75+2.96) x (0.1/0.045) = 17% for the diluted formulation. It should be noted that the *pro rata* correction for the spray dilution is considered worst-case since in some scenario's the dilution is not as low as 0.045 g/L.

For exposure to undiluted formulation dermal absorption was estimated to be 0.4%, based on the same *in vitro* human data with a correction for the large standard deviation. In case only data for combined exposure to undiluted and diluted formulation were available, a dermal absorption of 17% was used as a worst case assumption. For inhalatory exposure a default value of 100% was used, *i.e.* internal exposure equals external exposure.

The basic assumptions, input data and calculations used in the risk assessment are further specified below.

B.6.16.1 Operator exposure (IIIA 7.2.1)

Mechanical upward spraying on hop (field)

Application technique	:	tractor mounted upwards high volume sprayers

Input data

Concentration a.s. in formulation	:	200 g a.s. /L
Spray volume	:	2000-3300 L/ha
Concentration in spray liquid	:	4.5-7.5 g a.s. /hL
Application rate	:	0.150 kg a.s./ha
		(0.75 L product/ha)

Mechanical downward spraying on lettuce (field)

Application technique	:	Tractor mounted boomsprayer

Input data

Concentration a.s. in formulation	:	200 g a.s. /L
Spray volume	:	500-1000 L/ha
Concentration in spray liquid	:	12.5-25 g a.s./hL
Application rate	:	0.125 kg a.s./ha

(0.625 L product/ha)

Manual downward spraying on lettuce (field)

Application technique	:	Knapsack

Input data

Concentration a.s. in formulation	:	200 g a.s. /L
Spray volume	:	500-1000 L/ha
Concentration in spray liquid	:	12.5-25 g a.s./hL
Application rate	:	0.125 kg a.s./ha
		(0.625 L product/ha)

Manual spraying on lettuce (greenhouse)

Application technique	:	Knapsack

Input data

Concentration a.s. in formulation	:	200 g a.s. /L
Spray volume	:	500-1000 L/ha
Concentration in spray liquid	:	12.5-25 g a.s./hL
Application rate	:	0.125 kg a.s./ha
		(0.625 L product/ha)

B.6.16.1.1 Exposure estimates with UK-POEM

The model is largely based on unpublished studies, carried out in the UK by industry and MAFF. 75th percentiles are calculated.

B.6.16.1.1.1 Mechanical upward spraying on hops without PPE

For the present purpose, the model for 10 L bottles with 63 mm closure is used, as this is considered a reasonable worst case.

THE UK PREDICTIVE OPERATOR EXPOSURE MODEL (POEM)

Application method	Tractor-mounted/trailed broadcast air-assisted sprayer: 500 l/ha			
Product	BYI 02960 200 SL		Active substance	BYI 02960
Formulation type	water-based		a.s. concentration	200 mg/ml

B.6.16.1.2 Exposure estimates with the German model

The German model is based on unpublished studies performed by industry and all carried out in Germany. The chosen statistic is the geometric mean (GM).

B.6.16.1.2.1 Mechanical upward spraying on hop (field)

B.6.16.2 Bystander exposure (IIIA 7.2.2)

Mechanical upward spraying on hop (field)

Input data

Application rate : 0.150 kg/ha

Spray volume : 2000 L/ha

Dermal exposure : 5% of the application rate (kg/ha) on an body surface of 2 m^2 and dermal absorption of 17%

Inhalation exposure : 0.06 mL spraying liquid per m^3, a duration of 1 hour, a ventilation rate of 1.25 m^3/hour, and inhalation absorption of 100%.

Downward spraying on lettuce (field)

Input data

Application rate : 0.125 kg a.s./ha

Spray volume : 500 L/ha

Dermal exposure : 0.5% of the application rate (kg/ha) on body surface of 2 m^2 and dermal absorption of 17%

Inhalation exposure : 0.03 mL spraying liquid per m^3, a duration of 1 hour, a ventilation rate of 1.25 m^3/hour, and inhalation absorption of 100%.

Manual spraying on lettuce indoors

The presence of bystanders should be prohibited.

For bystander exposure during manual or mechanical downward spraying outdoors, no formally approved models exist. As an estimate, the draft values proposed for the EUROPOEM II model will be used. Since bystanding should as much as possible be prevented and will usually occur incidentally, it cannot be assumed that bystanders will be using any kind of personal protective equipment. Therefore, the use of this equipment is not considered in bystander risk assessment.

In greenhouses, no bystander exposure during application is considered, as Good Agricultural Practice requires absence of bystanders.

B.6.16.2.1 Exposure estimates with EUROPOEM II

The values represent the 90 th percentile exposure values for bystanders.

B.6.16.2.1.1 Mechanical upward spraying on hop (field)

B.6.16.2.1.3 Manual spraying on lettuce indoors

The presence of bystanders should be kept at a minimum. This can easily be achieved in greenhouses, where no person should be allowed who is not involved in the spraying process.

B.6.16.2.2 Risk assessment for bystanders

Table 6.16.2.2-1 Bystander internal exposure and risk assessment

Route	Estimated internal exposure (mg a.s./day)	AOEL systemic * (mg a.s./day)	%AOEL
Exposure during mechanical upward spraying on hop (field)

Total	**0.031**	**4.48**	**0.7**

* Assuming a body weight of 70 kg

B.6.16.3 Resident exposure (IIIA 7.2.2)

Risk assessment was performed according to the German guideline published in 2008 (Martin et al., 2008).

Inputdata

Dermal Exposure (via deposits caused by spray drift):

SDE_R = (AR x D x TTR x TC x H x DA) / BW

Where: SDE_R = Systemic Exposure of Residents via the Dermal Route (mg/kg bw/day)

AR = Application Rate (mg/cm^2) x 1 (for no. of applications)

BYI 02960: 0.125 kg a.s./ha x 1 = 0.00125 mg/cm^2 (lettuce)

0.150 kg a.s./ha x 1 = 0.00150 mg/cm² (hops)

D = Drift (%): 0.29 (lettuce), 5.77 (hops)

TTR = Turf Transferable Residues (%): 5

TC = Transfer Coefficient (cm^2/hour): 7300 (adult), 2600 (child)

H = Exposure Duration (hours): 2

DA = Dermal Absorption (%):

BYI 02960: 17%

BW = Body Weight (kg/person): 60 (adult), 16.15 (child)

Inhalation Exposure (Vapour Drift):

SIE_R = (AC_V x IR x IA) / BW

Where: SIE_R = Systemic Exposure of Residents via Inhalation (mg/kg bw/day)

AC_V = Airborne Concentration of Vapour (mg/m^3): vapour pressure of BYI 02960 is very low i.e.: 9.1 x 10^{-7} Pa at 20°C; acc. to guideline this corresponds to a non-volatile substance (vapour pressure <1 x 10^5 Pa at 20°C). Thus, resident inhalation exposure can be estimated as negligible. (i.e. airborne conc. of 0 mg/m^3)

IR = Inhalation Rate (m^3/day): 16.57 (adult), 8.31 (child)

IA = Inhalation Absorption (%): 100

BW = Body Weight (kg/person): 60 (adult), 16.15 (child)

Child Oral Exposure

Children's hand-to-mouth exposure

SOE_H = (AR x D x TTR x SE x SA x Freq x H x OA) / BW

Where: SOE_H = Systemic Oral Exposure via the Hand to Mouth Route (mg/kg bw/day)

AR = Application Rate (mg/cm^2) x 1 (for no. of applications)

BYI 02960: 0.125 kg a.s./ha x 1 = 0.00125 mg/cm^2 (lettuce)

0.150 kg a.s./ha x 1 = 0.00150 mg/cm² (hops)

D = Drift (%): 0.29 (lettuce), 5.77 (hops)

TTR = Turf Transferable Residues (%): 5

SE = Saliva Extraction Factor (%): 50

SA = Surface Area of Hands (cm^2): 20

Freq = Frequency of Hand-to-Mouth (events/hour): 20

H = Exposure Duration (hours): 2

OA = Oral Absorption (%):

BYI 02960: 100

BW = Body Weight (kg/person): 16.15

Children's object-to-mouth exposure

SOE_O = (AR x D x DFR x IgR x OA) / BW

Where: SOE_O = Systemic Oral Exposure via the Object to Mouth Route (mg/kg bw/day)

AR = Application Rate (mg/cm^2) x 1 (for no. of applications)

BYI 02960: 0.125 kg a.s./ha x 1 = 0.00125 mg/cm^2 (lettuce)

0.150 kg a.s./ha x 1 = 0.00150 mg/cm² (hops)

D = Drift (%): 0.29 (lettuce), 5.77 (hops)

DFR = Dislodgeable Foliar Residues (%): 20

IgR = Ingestion Rate for Mouthing of Grass/Day (cm^2):25

OA = Oral Absorption (%):
BYI 02960: 100
BW = Body Weight (kg/person): 16.15

Total Systemic Exposure of Residents

Adults: $SE_R = SDE_R + SIE_R$ (mg/kg bw/day)
Children: $SE_R = SDE_R + SIE_R + SOE_H + SOE_O$ (mg/kg bw/day)

Where:
SE_R = Systemic Exposure of Residents (mg/kg bw/day)
SDE_R = Systemic Dermal Exposure of Residents (mg/kg bw/day)
SIE_R = Systemic Inhalation Exposure of Residents (mg/kg bw/day)
SOE_H = Systemic Oral Exposure via the Hand to Mouth Route (mg/kg bw/day)
SOE_O = Systemic Oral Exposure via the Object to Mouth Route (mg/kg bw/day)

Corresponding exposure calculations are presented in the following.

Resident exposure after application with field (Lettuce, tractor mounted spray boom)

Resident Exposure

Dermal Exposure = AR*D*TRR*TC*H*DA/BW

	Dermal	0.956	0.191	4.48	21.3	4.3
	Total	**0.998**	**0.195**	**4.48**	**22.3**	**4.4**

* Assuming a body weight of 70 kg
- The inhalation exposure after field application is not quantifiable with this method. However, it can be expected to be lower than respiratory exposure during application.

B.6.16.5 Conclusions on risk assessments for operators, bystanders and workers

- Safe use for operators was identified for mechanical upward spraying in hopspotato, mechanical downward spraying in lettuce (field use), manual downward spraying in lettuce (field use), without the use of PPE (UK-POEM and German and models (field) and Dutch greenhouse model). Safe use for operators was identified for the manual spraying in lettuce (greenhouse use) with the use of PPE (UK-POEM).
- Safe use for bystanders and residents was identified for mechanical upward spraying in hop, mechanical downward spraying on lettuce tomato (field use) using the EUROPOEM II 2002 model and the German guidline by Martin *et al*., respectively. No bystanders should be present in the greenhouses during application.
- Safe use for workers was identified for re-entry in hops (field), and in lettuce (field and greenhouses) without the use of PPE (EUROPOEM II 2002 model).

FLUPYRADIFURONE

VOLUME 3

ANNEX B

B.7 Residues

Rapporteur Member State: The Netherlands

January 2014 November 2014 December 2014

Draft Assessment Report and Proposed Decision of the Netherlands prepared in the context of the possible approval of flupyradifurone under Regulation (EC) 1107/2009

Contents

B.7 Residue data 4
B.7.1 Metabolism, distribution and expression of residues in plants (IIA 6.2.1 and IIIA 8.2) 4
B.7.1.1 Primary crops 6
B.7.1.2 Succeeding and rotational crops (IIA 6.6.2) 76
B.7.2 Metabolism, distribution and expression of residues in livestock (IIA 6.2.2, IIA 6.2.3, IIA 6.2.4 and IIIA 8.2) 114
B.7.2.1 Summary of studies in ruminants and poultry 120
B.7.2.2 List of identified compounds 139
B.7.2.3 Metabolic pathway 140
B.7.3 Definition of the residue (IIA 6.7.1; IIIA 8.7.1) 144
B.7.3.1 Definition of the residue in plant material 144
B.7.3.2 Definition of the residue in animal products 146
B.7.4 Use pattern 148
B.7.5 Identification of critical GAPs 149
B.7.6 Residues resulting from supervised trials (IIA 6.3; IIIA 8.3) 150
B.7.6.1 Methods of analysis applied in the supervised trials 150
B.7.6.2 Supervised residue trials in lettuce 155
B.7.6.3 Supervised residue trials in hops 179
B.7.6.4 Storage stability (IIA 6.1) 187
B.7.6.5 Summary of storage stability studies 194
B.7.7 Effects of industrial processing and/or household preparation (IIA 6.5; IIIA 8.5) 195
B.7.7.1 Nature of the residue 195
B.7.7.2 Effects on residue levels 197
B.7.7.3 Summary of the processing studies 203
B.7.8 Livestock feeding studies (IIA 6.4; III 8.5) 204
B.7.9 Residues in succeeding or rotational crops (IIA 6.6; III 8.6) 236
B.7.9.1 Summary of studies in plants (succeeding crops) 273
B.7.10 Proposed pre-harvest intervals for envisaged use, or withholding periods, in the case of post-harvest uses (IIA 6.8; IIIA 8.8) 273
B.7.11 Community MRLs 273
B.7.12 Proposed EU MRLs and justification for the acceptability of those MRLs (IIA 6.7.2; IIIA 8.7.2) 274
B.7.12.1 Proposed MRLs 274
B.7.12.2 Justification of proposed MRLs 277
B.7.12.3 Summary of proposed MRLs 286
B.7.13 Proposed EU Import tolerances and justification for the acceptability of those residues .. 287
B.7.14 Basis for differences, if any, in conclusions reached having regard to established or proposed CAC MRLs 288

B.7.15 Estimates of potential and actual dietary exposure through diet and other means (IIA 6.9; IIIA 8.8) 288
B.7.15.1 Intakes by domestic animals 288
B.7.15.2 Intakes by humans (long-term) 288
B.7.15.3 National estimate for short term intake by humans (acute) 297
B.7.16 Summary and evaluation of residue behaviour (IIA 6.10; IIIA 8.9) 299
Annex I 320

B.7 Residue data

B.7.1 Metabolism, distribution and expression of residues in plants (IIA 6.2.1 and IIIA 8.2)

The metabolism of flupyradifurone has been investigated in the target plants apple, cotton, rice, tomato and potato, using different application techniques foliar and soil treatment, including tuber treatment, granular application and soil drench, and in confined rotational crops (CRC). The representative rotational crops were wheat, Swiss chard and turnips which were studied at three plant-back intervals after flupyradifurone was applied to the bare soil. The metabolism studies in primary crops were conducted at rates covering the anticipated worst case GAP, with flupyradiflurone formulated as 200 SL (for foliar and soil applications) and 480 FS (for seed treatment applications). In table 7.1-01 an overview of available metabolism studies is given.

Table 7.1.-01 Available metabolism studies

	Fruit / Fruiting vegetables	**Root and tuber vegetables**	**Pulses and oilseeds**	**Cereals / Rice**	**Leaf vegetables**
Foliar treatment	Apple 1) appl. at BBCH 69 2) appl. at BBCH 69 and at 14 days PHI	-	Cotton 1) appl. at BBCH 15-18 2) appl. at BBCH 15-18, and at 14 d. PHI	Paddy rice 1) appl. at BBCH 13-15 (1 day after transplantation), and at 30 days PHI	-
Soil/Seed treatment	Tomato 1) soil drench at BBCH 14-15 and 14 days later	Potato 1) Tuber treatment at BBCH 03 2) in-furrow spray at planting at BBCH 03	-	Paddy rice 2) Granular applications into the planting hole at transplantation	-
Rotational crops	-	Turnips plantback: 1, 4.5 and 10 months after soil appl.	-	Wheat plantback: 1, 4.5 and 10 months after soil appl.	Swiss chard plantback: 1, 4.5 and 10 months after soil appl.

As flupyradifurone contains separate ring systems, two different radiolabels were used in all plant and animal studies. These label positions are shown below:

* denotes position of radiolabel, labelled in the methyl group of the pyridinylmethyl moiety

[pyridinylmethyl-^{14}C]flupyradifurone

* denotes position of radiolabel, labelled in the 4-position of the furanone ring

[furanone-4-^{14}C]flupyradifurone

The notifier mentioned that during the investigation of the environmental fate of flupyradifurone, difluoroacetic acid (DFA) was found to be a major soil metabolite. Since this metabolite could not be detected by radioactivity in the ongoing plant metabolism (and CRC) studies with [furanone-4-^{14}C]- and [pyridinylmethyl- ^{14}C]flupyradifurone, all sample materials from the ongoing studies were analysed for DFA by LC-MS/MS to get an estimate of the residue levels. In addition, a target crop metabolism study with [ethyl- ^{14}C]flupyradifurone applied as a soil drench to tomato was conducted to address possible metabolites specific for this radiolabel and generate sample material with incurred residues for radiovalidation of extraction efficiency.

* denotes position of radiolabel, labelled in the ethyl group of the difluoroethyl amino moiety

[ethyl-1-^{14}C]flupyradifurone

Numerous metabolites were identified in the metabolism studies. The chemical structures and report names used in the summaries are given at the very end of this summary and in the List of Metabolites presented in Annex I.

All residue values given in mg/kg refer to parent compound equivalents if not indicated otherwise.

B.7.1.1 Primary crops

Study 1

Characteristics

Reference	:	Justus, K.; 2011a KIIA 6.2.1/01	Application rate	:	2 x 300 g a.s./ha; soil drench
Type of study	:	metabolism in plant	Total rate	:	600 g a.s./ha as soil drench
Year of execution	:	2009-2011	Area	:	greenhouse
Test substance	:	[furanone-4-^{14}C] Flupyradifurone; sample ID: KATH 6352; batch code BYI 02960-PU-01; purity 99.9% w/w	Plant	:	tomato
GLP statement	:	Yes	Sampling	:	fruit, flowers
Guideline	:	OECD 501, OPPTS 860.1300, PMRA Dir 98-02, Japanese MAFF, 12 Nousan 8147	Acceptability	:	acceptable

Study design

The metabolism of flupyradifurone in tomatoes was investigated corresponding the initially maximum envisaged use pattern in non-EU MSs as stated by the notifier, as part of the Global Joint Review of flupyradifurone, with currently a cumulative maximum of 0.45 kg as/ha. Four tomato plants (variety "Philona") were treated by soil drench application with [furanone-4-^{14}C]BYI 02960 (spec. radioactivity 35.5 µCi/mg; radiochemical purity >99%) formulated as SL 200. The first application was performed at BBCH 15 (5th leaf on main shoot unfolded) and a second application at BBCH 51 (1st inflorescence visible and first bud erect) which was 14 days later. Based on a planting density of 12,000 tomato plants/ha, the single application rate corresponded to 300 g a.s./ha; the total application rate was 600 g a.s./ha. Soil type was 85% white moor peat and 15% clay, enriched with water soluble nutrient salt mixture (ENS) and a pH of 5.8. Newly opened flowers were sampled 2-3 times a week starting at 6 days after the last application and continuing over a period of 30 days (until end of flowering). Fully ripe fruits were harvested 2-3 times a week from the remaining three plants, until no fruits were produced anymore (BBCH 89), which led to a harvest period (since tomato fruits ripen continuously) of 69 to 92 days after the last application.

An aliquot (500 g) of the harvested tomatoes (9.8 kg, total of 3 plants) and all collected flowers (4.1 g, from 1 plant) were homogenized and extracted four times with acetonitrile/water mixtures. The radioactivity in the extracts was determined by LSC and in the solids by combustion followed by LSC. After clean-up using a pre-conditioned SPE RP 18 cartridge, parent compound and metabolites in the extracts of tomato flowers and fruits were analysed by HPLC. Identification was performed by reverse phase HPLC and/or TLC co-chromatography with reference compounds as well as by comparison of HPLC profiles.

Results

Extraction released 85% and 94% of the TRR from the tomato fruits and flowers, respectively. Parent compound was the main component in both matrices and represented 36% of the TRR in fruits and 78% in flowers. Two major metabolites were detected in tomato fruits: glucose (or isomeric carbohydrates) (M45) represented 28% of the TRR, and BYI 02960-difluoroethyl-amino-furanone (DFEAF; M34) represented 10% of the TRR. In tomato flowers, DFEAF was detected as a minor

metabolite and represented 9.2% of the TRR; no radioactive glucose (or isomeric carbohydrates) was detected in flowers. The metabolite BYI-OH-glyc (M8) was a minor metabolite in tomato fruits and flowers and represented 5.5% and 6.6% of the TRR, respectively. One minor metabolite occurring in tomato fruits was not identified (4.3% of TRR and 0.004 mg/kg).

Conclusions

[Furanone-4-^{14}C]flupyradifurone was moderately metabolised in tomatoes. The following metabolic routes were observed:

- complete degradation of the furanone moiety and incorporation of carbon atoms into the natural compound pool, i.e. into glucose (or isomeric carbohydrates),
- cleavage of the pyridinylmethylamine bond and formation of BYI 02960-difluoroethylamino-furanone and
- hydroxylation of the methylene group of the furanone moiety followed by conjugation with glucose

On the basis of the results of this study, the following metabolic pathway is proposed (Figure 7.1.1-1).

Figure 7.1.1-1: Proposed metabolic pathway of [furanone-4-^{14}C]BYI 02960 in tomatoes

Guidelines & Limitations

The level of extraction, identification and characterisation of radioactivity in tomato is sufficient. The study results are acceptable.

STUDY 2

Characteristics

Type of study	:	metabolism in plant	Total rate	:	600 g a.s./ha as soil drench
Year of execution	:	2009-2011	Area	:	greenhouse
Test substance	:	[pyridinylmethyl-^{14}C] flupyradifurone; sample ID: KATH 6351; batch code BYI 02960-PU-01; purity 99.9% w/w	Plant	:	tomato
GLP statement	:	Yes	Sampling	:	fruit, flowers
Guideline	:	OECD 501, OPPTS 860.1300, PMRA Dir 98-02, Japanese MAFF, 12 Nousan 8147	Acceptability	:	acceptable

Study design

The study design is the same as described in study 1 (Justus 2011a), with the following changes:

- The radiolabel used is: [pyridinylmethyl-^{14}C]flupyradifurone with a specific radioactivity of 39.4 µCi/mg and radiochemical purity >98%.
- Sampling times were slightly different, for flowers: 3 to 36 days, and for fruits: 73-92 days after the last application.
- Weight of harvested tomato fruits was 9.1 kg (total of the 3 plants), weight of flowers was 7.6 g.

Results

Extraction released 99% and 97% of the TRR from the tomato fruits and flowers, respectively. Parent compound was a major component in both matrices and represented 24% of the TRR in tomato fruits and 66% in tomato flowers. In tomato fruits, the label-specific metabolite BYI 02960-CHMP-di-glyc (M23) was the main constituent (37% of the TRR), followed by parent compound and the label-specific metabolite 6-CNA (M27; 13% of the TRR). Another six metabolites were minor: BYI 02960-CHMP-glyc (M22; 5.1% of the TRR), BYI 02960-OH-glyc (M8; 3.4% of the TRR), BYI 02960-CHMP (M21; 3.3% of the TRR) and three unknown metabolites (<6% of TRR and <0.01 mg/kg). BYI 02960-CHMP is short for 6-chloro-3-hydroxymethanolpyridine.
In tomato flowers, parent compound represented the predominant portion besides four minor metabolites. The minor metabolites were identical with the metabolites identified in the tomato fruits, except for BYI 02960-CHMP, which was not present in flowers.

Conclusions

[Pyridinylmethyl-^{14}C]flupyradifurone was moderately metabolised in tomatoes. The following metabolic routes were observed:

- cleavage of the pyridinylmethylamine bond followed by conjugation with carbohydrates or followed by oxidation of the methylene group to a carboxylic group, which were the major metabolic routes, and
- hydroxylation of the methylene group of the furanone moiety followed by conjugation with glucose, which was the minor metabolic route.

On the basis of the results of this study, the following metabolic pathway is proposed (Figure 7.1.1-2).

Figure 7.1.1-2: Proposed metabolic pathway of [pyridinylmethyl-^{14}C]BYI 02960 in tomatoes

Guidelines & Limitations

The level of extraction, identification and characterisation of radioactivity in tomato is sufficient. The study results are acceptable.

Study 3

Characteristics

Reference	:	Unold, M, Justus, K.; 2011 KIIA 6.2.1/03	Application rate	:	2 x 300 g a.s./ha; soil drench
Type of study	:	metabolism in plant	Total rate	:	600 g a.s./ha as soil drench
Year of execution	:	2010-2011	Area	:	greenhouse
Test substance	:	[ethyl-1-^{14}C] Flupyradifurone ; sample ID: KATH 6315; batch code BYI 02960-PU-01; purity 99.9% w/w	Plant	:	tomato
GLP statement	:	Yes	Sampling	:	fruit, flowers
Guideline	:	OECD 501, OPPTS 860.1300, PMRA Dir 98-02, Japanese MAFF, 12 Nousan 8147	Acceptability	:	acceptable

Study design

The study design is the same as described in study 1 (Justus 2011a), with the following changes:

- The radiolabel used is: [ethyl-1-^{14}C]flupyradifurone with a specific radioactivity of 35.5 µCi/mg and radiochemical purity >99%.
- Three in stead of four tomato plants were treated by soil drench application.

- Application and sampling times were slightly different. Soil drench was applied at BBCH 14-15 and than again 14 days later, as in study 1 and 2, but BBCH code was than 51-59. Flowers were sampled 1 to 32 days, and fruits 56 to 86 days after the last application, as tomatoes apparently ripened some more rapidly than in study 1 and 2.
- Weight of harvested tomato fruits was 6.1 kg (total from 2 plants) and 9.8 g of collected flowers. Aliquot of tomato sample for homogenization was 100 g, and of flowers 5.0 g.
- Samples were extracted three in stead of four times with acetonitrile/water mixtures.

Results

Extraction released more than 98% of the TRR from both tomato fruit and flower samples.
Besides parent compound, one major metabolite and two minor metabolites were identified.

The label-specific metabolite difluoroacetic acid (DFA; M44) was the main component detected in both matrices and represented 87% of the TRR in tomato fruits and 60% in tomato flowers. Since difluoroacetic acid was also detected as a major soil metabolite in the aerobic soil degradation studies, it can be expected that at least a part of the residues detected in tomato fruits and flowers originated from the uptake of the soil metabolite. Parent compound was the second major component in tomato fruits and flowers and represented 10% and 33% of the TRR, respectively. BYI 02960-OH-glyc (M8) and DFEAF (M34) were minor metabolites (<5% of the TRR) detected in fruits and flowers.

* PES = post extraction solids

Conclusions

[Ethyl-1-^{14}C]flupyradifurone was metabolised to a significant extent in tomatoes. The following metabolic routes were observed:

- oxidative cleavage of the difluoroethylamine bond and formation of difluoroacetic acid (this degradation process occurs also in the soil and thus uptake of difluoroacetic acid from the soil is supposed as well)
- cleavage of the pyridinylmethylamine bond and formation of difluoroethylamino-furanone, and
- hydroxylation of the methylene group of the furanone moiety followed by conjugation with glucose

Since it is known that parent degrades to difluoroacetic acid in soil, the difluoroacetic acid residue is probably the result of both uptake of this metabolite from the soil and degradation of the parent compound BYI 02960 in the plant. On the basis of the results of this study, the following metabolic pathway is proposed (Figure 7.1.1-3).

Figure 7.1.1-3: Proposed metabolic pathway of [ethyl-1-^{14}C]BYI 02960 in tomatoes

Guidelines & Limitations

The level of extraction, identification and characterisation of radioactivity in tomato is sufficient. The study results are acceptable.

Overall conclusion metabolism in tomato (soil drench)

The metabolism of flupyradifurone was investigated in tomato fruits and flowers following two soil drench applications. Three studies were performed, each using flupyradifurone radioactively labeled at one of the three side groups of the central amine. Total radioactive residue was measured in fruits (70 to 106 days after the first, and 56 to 92 days after the last application) and flowers (15-50 days after

the first, and 1 to 36 days after the last application). Metabolites were identified or characterized as unknown, dependent on levels found.

At harvest, the total radioactive residue (TRR) in the tomato fruits was 0.10 mg/kg (furanone ring label), 0.13 mg/kg (pyridinylmethyl label) and 0.20 mg/kg (difluoroethyl label). Percentage of parent compound varied from 36% (furanone ring label) and 24% (pyridinylmethyl label) to 10% of TRR (difluoroethyl label).

One major metabolic route in the furanone ring label study was the complete degradation of the furanone moiety and incorporation of the carbon atoms into the natural compound pool, i.e. most probably into glucose (28% of TRR of furanone ring label). Another important route in the furanone ring label study was cleavage of the pyridinylmethylamine bond, forming DFEAF (10% of TRR). The cleavage of this bond was also detected in the studies conducted with the other 2 radiolabels, as DFEAF was also detected in the difluoroethyl label study (2.2% of TRR), and in the pyridinylmethyl label study, CHMP (whether or not conjugated to glycoside or diglycoside, together 45% of TRR) and 6-CNA (13%) were identified as corresponding counterparts to a total of 58% of TRR. 6-CNA is formed from CHMP by oxidation of the methylene group to a carboxylic group.

A minor metabolic route in all three studies was the hydroxylation of the methylene group of the furanone moiety, followed by conjugation with glucose. This metabolic route resulted in the non-label specific metabolite BYI 02960-OH-glyc, which accounted for 5.5%, 3.4% and 0.6% of TRR found in tomato fruit from studies with furanone ring, pyridinylmethyl, and difluoroethyl label, respectively.

In the study conducted with difluoroethyl label, the TRR (0.20 mg/kg) was significantly higher, and percentage parent compound (10%) significantly lower than in the metabolism studies conducted with the other two labels. The major metabolite found in the study with difluoroethyl label was difluoroacetic acid (DFA). Since it is known that flupyradifurone degrades to DFA in soil, the measured DFA residue is probably not only the result of degradation of the parent compound in the plant, but also from uptake of this metabolite from the soil. This uptake of radioactive DFA results in a higher amount of TRR, and consequently lower percentage of parent compound of TRR than in the other two metabolism studies, where the DFA taken up from the soil is not radioactively labeled.

The major metabolic route in the study with difluoroethyl label was oxidative cleavage of the difluoroethylamine bond, forming DFA (87% of TRR, partly taken up from soil). Minor routes were cleavage of the pyridinylmethylamine bond, forming DFEAF (2.2% of TRR) and hydroxylation of the methylene group of the furanone moiety, followed by conjugation with glucose, forming BYI 02960-OH-glyc (0.6% of TRR). Percentages of these two metabolites are lower than in the other studies partly because of higher TRR value due to the contributing radioactivity of DFA taken up from the soil.

When considering the results from all metabolism studies conducted on tomato, it can be concluded that flupyradifurone is rather extensively metabolised in this crop. A total of 6 major and 6 minor metabolites were found, and all major and 3 minor have been identified. The distribution of parent compound and metabolites in the edible commodity tomato fruits is summarized in Table 7.1.1-4.

[a] probably partly taken up from the soil
Label specific metabolites are printed in italics

On basis of the metabolites identified, biotransformation of flupyradifurone in tomato proceeds by the following pathways:

- oxidative cleavage of the difluoroethylamine bond and formation of difluoroacetic acid (DFA)
- complete degradation of the furanone moiety and incorporation of carbon atoms into the natural compound pool, e.g. into glucose/carbohydrates
- cleavage of the pyridinylmethylamine bond and formation of BYI 02960-difluoroethylamino-furanone and its corresponding counterpart BYI 02960-CHMP, which was either conjugated with carbohydrates or oxidised to 6-chloronicotinic acid (6-CNA)
- hydroxylation of the furanone moiety followed by conjugation with glucose (formation of BYI 02960-OH-glyc)

The positions involved in the metabolic degradation are summarised in Figure 7.1.1-4.

Figure 7.1.1-4: Positions involved in metabolic degradation of BYI 02960 in tomato fruits and flowers

Study design

The metabolism of flupyradifurone in potatoes was investigated in two experiments in potatoes (variety “Cilena”). In one experiment, three seed potato tubers were treated immediately prior to planting (BBCH 03) with [furanone-4-^{14}C]BYI 02960 (spec. radioactivity 106 µCi/mg; radiochemical purity >99%), formulated as FS 480, at an application rate of 10.0 g a.s./dt. Based on a seed density of 25 dt/ha (1 dt (deciton) is 100 kg), the application rate corresponded to 254 g a.s./ha. In the other experiment, the radioactive [furanone-4-^{14}C]BYI 02960 was formulated as an SL 200 and was sprayed in the furrow onto the soil at an application rate of 626 g a.s./ha (based on a seed density of 22 dt/ha) prior to planting of the seed potatoes (BBCH 03). According to the notifier, the target rates correspond to the initially anticipated maximum application rates for the two use types, which is currently maximally 450 g a.s./ha, as part of the Global Joint Review of flupyradifurone. Soil type used was sandy loam with a pH of 6.8. The potato tubers were harvested at maturity (BBCH 97; 3.3-3.5 kg), which was 97 days after the last application. Concurrently, the leaves and roots (0.23 kg) as well as the remainders of the seed potatoes (0.03-0.06 kg) were sampled to determine the TRR by combustion analysis. Potato tubers were cut into small cubes which were randomized by shuffling and stored frozen <-18°C.

Aliquots (300 g) of randomized potato cubes of each experiment were homogenized and extracted four times with acetonitrile/water mixtures. The remaining solids after conventional extraction of the potato tubers in the in-furrow treatment experiment were subjected two times to exhaustive extraction with acetonitrile/water (1:1, v/v) under microwave assistance (120°C for 20 min.). The radioactivity in the extracts was determined by LSC and in the solids by combustion followed by LSC. After clean-up using a pre-conditioned SPE RP 18 cartridge, parent compound and metabolites in the extracts of potato tubers were analysed by HPLC. Identification was performed by HPLC co-chromatography with reference compounds and/or by comparison of HPLC profiles.
In the tuber treatment experiment, the solids remaining after conventional extraction amounted to 0.026 mg/kg.. Since the distribution of the radioactivity in the extracts and solids after conventional extraction was nearly identical within the in-furrow and the tuber treatment experiments and the conventional extracts showed a very similar metabolite pattern, exhaustive extraction of the solids of the tuber treatment experiment was not considered necessary.

Results

At harvest, the total radioactive residues (TRR) in potato tubers were 0.078 mg a.s equiv./kg after tuber treatment and 0.17 mg a.s equiv./kg after in-furrow application. The TRR values were considerably higher in the remaining plant parts: leaves and roots: 7 mg a.s equiv./kg and remainders of the seed potatoes: 3.4 up to 36 mg/kg in seed treated potatoes. These plant parts were only sampled for optional analysis to support identification of metabolites, if needed.
Extraction of the homogenized potato tuber released 67% of TRR from in the tuber treatment experiment and 75% of the TRR in the in-furrow application experiments. Flupyradifurone was moderately metabolised in potatoes into six metabolites. Parent compound was the only major component (i.e. >10% of TRR) and represented 40% and 57% of the TRR in potato tubers, respectively. All metabolites were minor, each representing less than 10% of TRR and being below 0.01 mg/kg. Besides parent compound, two minor metabolites were identified: BYI 02960--OH-glyc (M8) and DFEAF (M34). The amounts of parent compound and metabolites are shown in Table 7.1.1-5.

Conclusion

[Furanone-4-^{14}C]flupyradifurone was moderately metabolised in potatoes. The following metabolic routes were observed:

- hydroxylation of the methylene group of the furanone moiety followed by conjugation with glucose, and
- cleavage of the pyridinylmethylamine bond.

On the basis of the results, the following metabolic pathway is proposed (Figure 7.1.1-5).

Figure 7.1.1-5: Proposed metabolic pathway of [furanone-4-^{14}C]flupyradifurone in potato tubers

Guidelines & Limitations

The level of extraction, identification and characterisation of radioactivity in potato is sufficient. The study results are acceptable.

Study design

The study design is the same as described in study 4 (Justus 2011c), with the following changes:

- The radiolabel used is [pyridinylmethyl-^{14}C]flupyradifurone with a specific radioactivity of 118 µCi/mg and radiochemical purity >99%.
- A slightly different application rate was used. The tuber treatment with FS 480 was applied at a rate of 10.0 g a.s./dt. Based on a seed density of 27 dt/ha, the application rate corresponded to 270 g a.s./ha. The SL 200 formulation was sprayed in the furrow onto the soil at an application rate of 626 g a.s./ha (based on a seed density of 28 dt/ha) prior to planting of the seed potatoes.

- No exhaustive extraction by use of microwave was performed
- Weight of harvested potatoes was 3.4 kg in both experiments. Weight of leaves and roots was 0.25-0.29 kg, and of remainders of the seed potato 0.007-0.016 kg.

Results

At harvest, the total radioactive residues (TRR) in potato tubers were 0.076 mg a.s equiv./kg after tuber treatment and 0.12 mg a.s equiv./kg after in-furrow application. The TRR values were considerably higher in the remaining plant parts: leaves and roots (appr. 100x) and remainders of the seed potatoes (7 to 33 mg a.s. equiv/kg). Extraction of the homogenized potato tuber released 93% and 90% of TRR from in the tuber and in-furrow treatment experiments, respectively. Flupyradifurone was moderately metabolised in potatoes into seven metabolites. Parent compound and 6-CNA (M27) were the only major components (i.e. >10% of TRR) and represented 40-44% and 18-22% of TRR (0.02 mg a.s. equiv./kg) in potato tubers, respectively. All other metabolites representing less than 10% of TRR and being below 0.01 mg/kg. Amounts of parent compound and metabolites are shown in Table 7.1.1-6.

Conclusion

[Pyridinylmethyl-^{14}C]flupyradifurone was moderately metabolised in potatoes. The following metabolic routes were observed:

- cleavage of the pyridinylmethylamine bond followed by conjugation with carbohydrates or by oxidation of the methylene group to a carboxylic group and conjugation with carbohydrates or derivatives, which were the major metabolic routes, and
- hydroxylation of the methylene group of the furanone moiety followed by conjugation with glucose, which was the minor metabolic route

On the basis of the results of this study, the following metabolic pathway is proposed (Figure 7.1.1-6).

Figure 7.1.1-6: Proposed metabolic pathway of [pyridinylmethyl-^{14}C]flupyradifurone in potatoes

Guidelines & Limitations

The level of extraction, identification and characterisation of radioactivity in potato is sufficient. The study results are acceptable.

Overall conclusion on metabolism in potato (tuber treatment and in-furrow application)

The metabolism of flupyradifurone was investigated in potatoes in two studies following tuber or soil application with furanone and pyridinylmethyl label. The metabolite profiles of all tuber extracts were very similar, and at harvest, the predominant portion was always parent compound. However, subsequent analysis of the extracts on the non-radiolabelled metabolite difluoroacetic acid - which

cannot be detected with the radiolabels used - revealed even higher concentrations of this metabolite compared to the parent compound (see study 12).

In studies with furanone-labelled flupyradifurone, besides parent compound, six minor metabolites were detected, two of them were identified: BYI 02960-OH-glyc, a metabolite common to both radiolabels tested, and BYI 02960-difluoroethyl-aminofuranone, a metabolite specific to the furanone-label. The metabolites identified were also detected in tomato fruits after soil application and in the confined rotational crop studies. In studies with pyridinylmethy-labelled flupyradifurone, only one major metabolite (6-CNA) was detected besides parent compound. Additionally, eight minor metabolites were detected, five thereof were identified: BYI 02960-OH-glyc, a metabolite common to both radiolabels tested, and the label-specific metabolites BYI 02960CHMP, BYI 02960-CHMP-glyc, BYI 02960-CHMP-di-glyc and 6-CNA-glycerol-gluA. These metabolites or at least the aglycons were also detected in tomato fruits after soil application.

The major metabolic routes in this study were cleavage of the pyridinylmethylamine bond followed by conjugation with carbohydrates or by oxidation of the methylene group to a carboxylic group. A minor metabolic route was hydroxylation of the methylene group of the furanone moiety followed by conjugation with glucose. This metabolic route resulted in the non-label specific metabolite BYI 02960-OH-glyc, which was identified in nearly identical concentrations in both potato studies.
It can be concluded that BYI02960 is moderately metabolised in potato. A total of 2 major and 10 minor metabolites were found, and the 2 major and 6 of the 10 minor have been identified. The distribution of parent compound and metabolites in the edible commodity potato tuber is summarized in Table 7.1.1-7.

In order to gain information on the fate of the difluoroethane moiety of flupyradifurone, the tuber extracts obtained in the potato metabolism study with [pyridinylmethyl-^{14}C]BYI 02960 were additionally analysed for non-radiolabelled difluoroacetic acid by LC-MS/MS according to residue method 01304 (see study 12). High levels of this metabolite were found. After tuber treatment and in-furrow application, difluoroacetic acid accounted for 0.13 and 0.18 mg/kg in potato tubers, which, corrected for difference in molecular weight with a factor 3, is equal to 0.39 and 0.54 mg a.s. equivalent/kg. These concentrations are by a factor of approx. 10 higher compared to those of the parent compound indicating that difluoroacetic acid is the main residue in potato tubers. Since it is known that flupyradifurone degrades to difluoroacetic acid in soil, the high concentration of difluoroacetic acid is probably the result of both uptake of this metabolite from the soil and degradation of the parent compound in the plant.

Label specific metabolites are printed in italics.

These studies show that the metabolism of flupyradifurone in potato proceeds by the same pathways as the one presented for tomatoes (see Figure 7.1.1-4). The only difference is that the degradation step of the furanone moiety (incorporation of its carbon atoms into the natural compound pool) has not been demonstrated in the potato metabolism studies.

CH = canopy height

Study design

The metabolism of flupyradifurone in apple was investigated in two experiments in apple trees (variety “James Grieve”) after foliar spray application. In one experiment (single foliar spray application), two

apple trees were treated with [furanone-4-^{14}C]BYI 02960 (spec. radioactivity 53 µCi/mg; radiochem. purity >99%), formulated as SL 200, at an application rate of 86 g a.s./ha/mCH (meter canopy height) at the end of flowering (BBCH 69, PHI = 98 days). In the other experiment (double foliar spray application), one apple tree was treated two times at a rate of 86 g a.s./ha/mCH per application. The application rates are calculated using a planting density of 3000 trees/ha. The first application was conducted at the end of flowering (BBCH 69) and the second at 14 days before harvest. The actual application rates of 86 g a.s./ha/mCH were slightly above the target rate of 75 g a.s./ha/mCH, which corresponds to the maximum application rates on apples of maximally 410 g/ha as stated by the notifier, as part of the Global Joint Review of flupyradifurone.
The apple trees used in the present study had a canopy height (CH) of 0.5 m and were cultivated in sandy loam soil with a pH of 6.8, in a planting container with a surface area of 0.091 m^2. The plants were grown in a glass-roofed vegetation area (natural temperature and light conditions). The apple fruits (3.1 and 1.4 kg respectively for single and double treated appletrees) were harvested at maturity (BBCH 87-89). Concurrently, leaves were sampled (0.30 and 0.13 kg, resp.) to determine the TRR and to support the analysis of metabolites. All apple fruits of single treated and one-third of double treated apples were cut in pieces and pieces were mixed, divided in aliquots and stored frozen at <-18°C. Remaining whole apple fruit was stored overnight at room temperature and than surface washed with dichloromethane.

Aliquots (300 g) of apple pieces of each experiment were homogenized and extracted four times with acetonitrile/water mixtures. The remaining solids after conventional extraction of the apple fruits were additionally subjected two times to exhaustive extraction with acetonitrile/water (1:1, v/v) under microwave assistance (120°C for 20 min.) and/or to enzymatic treatment with cellulase (3 days at room temperature). The radioactivity in the extracts and surface wash (dichloromethane) was determined by LSC and in the solids by combustion followed by LSC. After clean-up using a pre-conditioned SPE RP 18 cartridge, parent compound and metabolites in the surface wash and extracts of apple fruits and leaves, were analyses by reversed phase HPLC coupled to a radioactivity detector with a glass scintillator cell. Identification was performed by comparing the HPLC profiles with those obtained in the apple metabolism study with [pyridinylmethyl-^{14}C]BYI 02960, or by HPLC co-chromatography with authentic reference compounds.

Results

At harvest, the total radioactive residues (TRR) were 0.28 and 1.1-1.3 mg a.s eq./kg in apples treated once and twice by foliar application, respectively. In total, 87% to 97% of the TRR was extracted from the apple matrices. Of apples of the double application experiment, a portion of 7.5% of the TRR was removed by the surface wash, another portion of 81.9% was extracted conventionally and 3.9% of the TRR was extracted after treatment with cellulase. In leaves the TRR was 39 and 103 mg a.s. eq./kg. resp.

In total, 80% to 93% of the TRR was identified in apple fruits and leaves. The residues were dominated by parent compound in the double application experiment due to the late second application. However, irrespective of the amounts, the vast majority of metabolites was identical in the single and double application experiments. Flupyradifurone was metabolised in apples into a large number of metabolites. Parent compound was the major component in the profiles of the double application experiment and represented 71% and 74% of the TRR in the fruits and 58% of the TRR in the leaves. In the single application experiment, parent compound represented 7.4% of the TRR in the fruits and 26% of the TRR in the leaves. Glucose/carbohydrates (M45) was the only major metabolite (>10% of the TRR) in apple fruits, occurring at up to 72% of the TRR. The metabolite BYI 02960-OH-glyc (M8) was the only major metabolite in apple leaves, occurring at 36% and 17% of the TRR. All other metabolites were minor and occurred at < 7% of the TRR in the apple matrices. ~~DFEAF (M34),~~ BYI 02960-acetic acid-glyc (M16), BYI 02960-OH-glyc (M8), BYI 02960-acetic acid (M15) and BYI 02960-OH (M3) were detected in (washed) apple fruits and leaves, whereas DFEAF (M34) and BYI 02960-DFE-OH-glyc (M11) were only detected in apple leaves. Additional details about the amounts of parent compound and metabolites are shown in Tables 7.1.1-8 and Tables 7.1.1-9.

Conclusion

The residues were dominated by parent compound in the double application experiment, whereas the metabolite pattern was very similar in both experiments.

Four major metabolic routes of [furanone-4-^{14}C]BYI 02960 were observed in apples:

- hydroxylation of the furanone or the difluoroethyl moiety followed by conjugation with carbohydrates,
- complete degradation of the furanone moiety and incorporation of carbon atoms into the natural compound pool, i.e. into glucose/carbohydrates,
- oxidative degradation of the furanone moiety to an acetic acid group followed by conjugation with a carbohydrate, and
- cleavage of the pyridinylmethylamine bond.

On the basis of the results of this study it is concluded that the metabolism of [furanone-4-^{14}C]-BYI 02960 in apples, the metabolic pathway is proposed as shown in Figure 7.1.1-7.

Guidelines & Limitations

The level of extraction, identification and characterisation of radioactivity in apple is sufficient. The study results are acceptable.

Study design

The study design is the same as described in study 6 (Justus 2011e), with the following changes:

- The radiolabel used is: [pyridinylmethyl-^{14}C]flupyradifurone with a specific radioactivity of 59 µCi/mg and radiochemical purity >98%.
- Application rates were slightly different, i.e. in stead of 86 g a.s./ha/mCH, the application rate was 87 g a.s./ha/mCH at the first treatment (both experiments), and 85 g a.s./ha/mCH at the second treatment (double application experiment only).
- Weight of harvested apple fruits was 4.3 and 1.7 kg, weight of leaves was 0.24 and 0.11 kg in single and double application experiments, respectively. Sample weights were 100 or 300 g for apple fruits and and 2 to 5 g for leaves.

Identification and characterisation:

Generally, major metabolites were identified by two independent chromatographic methods (reversed phase HPLC and normal phase TLC) or by LC-MS/MS after semi-preparative isolation of the compounds. Enzymatic treatment with ß-glucosidase was also used.

Since the profiles of the apple leaves showed higher levels of metabolites than the profiles of apple fruits (in terms of mg/kg), several metabolites were isolated with semi-preparative HPLC from the extract of apple leaves of the single treatment experiment. The isolated compounds were identified with spectroscopic methods, even if they were minor. The isolated and identified metabolites were furthermore used as reference compounds for co-chromatographic identification of metabolites in apple fruits. Other minor metabolites (<10% of the TRR and representing <0.01 mg/kg in edibles) were identified by HPLC co-chromatography with authentic reference compounds or by comparison of HPLC profiles.

Results

The TRR level in the apple fruits was 0.079 mg/kg in single application experiment and 1.9 (extraction including surface wash) and 0.55 mg/kg (extraction without surface wash) in double application experiment. The difference of the TRR values of double treated apples is presumably due to the low

amount of apples harvested and extracted and a partly inhomogeneous spray distribution. The TRR values of the apple leaves were 57 mg/kg in leaves of the single application experiment and 135 mg/kg in leaves of the double application experiment. Apple leaves were sampled to support the identification of metabolites.

In apple fruits and leaves the metabolites 6-CNA (M27), BYI 02960-CHMP-glyc (M22), BYI 02960-CHMP (M21), BYI 02960-acetic acid-glyc (M16), BYI 02960-OH-glyc (M8), BYI 02960-acetic acid (M15), BYI 02960-DFE-OH-glyc (M11), BYI 02960AMCP-difluoroethanamine (M36) and BYI 02960-OH (M3) were identified. The metabolite BYI 02960-CHMP-di-glyc was identified only in the leaves. In apple fruits all metabolites were minor (< 10% of the TRR). In apple leaves several minor and the following two major metabolites were detected and identified: BYI 02960-OH-glyc (19.9% and 15.4% of the TRR) and BYI 02960-CHMP-glyc (14.4% and 7.3% of the TRR). Additional details about the amounts of parent compound and metabolites are shown in Tables 7.1.1-10 and 7.1.1-11.

Conclusions

The residues were dominated by parent compound in the double application experiment, whereas the metabolite pattern was the same in both experiments. Three major metabolic routes of [pyridinylmethyl-^{14}C]BYI 02960 were observed in apples:

- hydroxylation followed by conjugation with carbohydrates,
- cleavage of the pyridinylmethylamine bond followed by conjugation with carbohydrates or by oxidation of the methylene group to a carboxylic group, and
- oxidative degradation of the furanone moiety to an acetic acid group followed either by conjugation with a carbohydrate or by further degradation of the moiety.

On the basis of the results of this study it is concluded that the metabolism of [pyridinylmethyl-^{14}C]-BYI 02960 in apples is well understood and the metabolic pathway is proposed in Figure 7.1.1-8.

Figure 7.1.1-8: Proposed metabolic pathway of [pyridinylmethyl-^{14}C]BYI 02960 in apples

Guidelines & Limitations

The level of extraction, identification and characterisation of radioactivity in apple is sufficient. The study results are acceptable.

Overall conclusions apple (foliar application)

The metabolism of flupyradifurone was investigated in apple fruits in two studies following foliar application with furanone- or pyridinylmethyl-labeled flupyradifurone. In order to gain information on the fate of the difluoroethane moiety of flupyradifurone, the extracts obtained in the apple metabolism study with [furanone-4-^{14}C]BYI 02960 were additionally analysed for non-radiolabelled difluoroacetic acid by LC-MS/MS according to residue method 01304 (see study 12). In both metabolism studies, single and double application experiments were done.

Furanone-labeled flupyradifurone

In the single application experiment a natural compound (glucose/carbohydrates) was by far the main compound in apple fruits, whereas parent compound was predominant in leaves. Nevertheless, the metabolite patterns were very similar in fruits and leaves in both experiments. Besides parent compound and glucose/carbohydrates, each of the other metabolites in apple fruits represented less than 4% of the TRR. In total, 5 and 6 metabolites were identified in the single and the double application experiment, respectively. In apple leaves, BYI -OH-glyc was identified as major metabolite, each of the other metabolites (6 to 7) represented less than 7% of the TRR. Overall, four major metabolic routes were detected: (1) hydroxylation of the parent compound (either the furanone moiety or the difluoroethyl moiety) followed by conjugation with carbohydrates, (2) oxidative degradation of the furanone moiety to an acetic acid group followed either by conjugation with a carbohydrate or by further degradation of the moiety, (3) complete degradation of the furanone moiety and incorporation of carbon atoms into the natural compound pool, i.e. into glucose/carbohydrates, and (4) cleavage of the pyridinylmethylamine bond.

The first two routes led to the non label-specific metabolites BYI -acetic acid and BYI -OH, their corresponding glycosides and to BYI -difluoroethyl-OH-glyc, which was detected in apple leaves only. These metabolites were also detected in the apple metabolism study with [pyridinylmethyl-^{14}C]BYI 02960. Molecule cleavage led to the label-specific metabolite BYI 02960-difluoroethyl-amino-furanone and degradation of the furanone moiety finally to glucose/carbohydrates. The corresponding counterparts CHMP and AMCP-difluoroethanamine were detected in the apple metabolism study with [pyridinylmethyl-^{14}C]BYI 02960. Thus, the results of the present metabolism study in apples are in very good conformity with the results of the corresponding study performed with [pyridinylmethyl-^{14}C]BYI 02960.

Pyridinylmethyl-labeled flupyradifurone

Parent compound was the main compound detected in both experiments in apple fruits at harvest. All metabolites represented less than 10% of the TRR. Nine metabolites were identified in fruits from which BYI 02960-AMCP-difluoroethanamine was the most prominent one, followed by 6-CNA (single application experiment) or BYI 02960-OH-glyc (double application experiment). Overall, three major metabolic routes were detected: (1) Oxidative degradation of the furanone moiety to an acetic acid group followed either by conjugation with a carbohydrate or by further degradation of the moiety; (2)

hydroxylation of the parent compound (either the furanone moiety or the difluoroethyl moiety) followed by conjugation with carbohydrates and (3) cleavage of the pyridinylmethylamine bond followed by conjugation with carbohydrates or by oxidation of the methylene group to a carboxylic group.
The first two routes led to the non label-specific metabolites BYI -acetic acid and BYI -OH, their corresponding glycosides and to BYI -difluoroethyl-OH-glyc. These metabolites were also detected in the apple metabolism study with the furanone label. Molecule cleavage led to the label-specific metabolites AMCP-difluoroethaneamine, 6-CNA, CHMP and its corresponding glycoside. The corresponding counterpart difluoroethyl-amino-furanone (DFEAF) was detected in the apple metabolism study with [furanone-4-^{14}C]BYI 02960. Thus, the results of the present metabolism study in apples are in good conformity with the results of the corresponding study performed with [furanone-4-^{14}C]BYI 02960.
When considering the results from both metabolism studies conducted on apple, it can be concluded that flupyradifurone is rather extensively metabolised in this crop. A total of 3 major (one in apple fruits and 2 in leaves) and more than 20 minor metabolites (5 thereof in fruits) were found. All major and 10 minor metabolites have been identified. The distribution of parent compound and metabolites in the edible commodity apple fruit is summarized in Table 7.1.1-12.

Label specific metabolites are printed in italics.

Analysis of apple fruit and leave extracts on the non-radiolabelled metabolite difluoroacetic acid revealed that this metabolite represents a significant proportion of the residue. In apple fruits, difluoroacetic acid accounted for 0.23 mg/kg, corresponding to 0.69 mg a.s. equiv./kg in the single application experiment and represented by far the highest residue. In the double experiment difluoroacetic acid accounted for 0.04 mg/kg or 0.12 mg a.s. equiv./kg and was thus a main metabolite. Only parent compound and the natural compound glucose were detected in higher concentrations. In leaves quite high concentrations of difluoroacetic acid were found (1.9 mg a.s. equiv/kg in the single application experiment and 1.4 mg a.s. equiv./kg in the double application experiment, see study 12), however the proportions were low compared to the total radioactive residue detected.

On basis of the metabolites identified, biotransformation of BYI 02960 in apple proceeds by the following pathways:

- oxidative cleavage of the difluoroethylamine bond and formation of difluoroacetic acid

- oxidative degradation of the furanone moiety to an acetic acid group followed either by conjugation with a carbohydrate or by further degradation of the moiety
- complete degradation of the furanone moiety and incorporation of carbon atoms into the natural compound pool, e.g. into glucose/carbohydrates
- cleavage of the pyridinylmethylamine bond and formation of difluoroethylamino-furanone and its corresponding counterpart CHMP, which was either conjugated with carbohydrates or oxidised to 6-chloronicotinic acid (6-CNA)
- hydroxylation of the furanone or difluoroethane moiety followed by conjugation with glucose or another hexose

The positions involved in the metabolic degradation are summarised in Figure 7.1.1-8.

Figure 7.1.1-8: Positions involved in metabolic degradation of BYI 02960 in apple fruits and leaves

Study design

The metabolism of flupyradifurone in cotton was investigated in cotton (*Gossypium hirsutum*, variety: Carmen), after foliar spray application. In one experiment (single application experiment), five cotton plants were treated with [furanone-4-^{14}C]BYI 02960 (specific radioactivity: 106 µCi/mg; radiochemical purity >98%) formulated as SL 200, at an actual application rate of 209 g a.s./ha when the sixth true leaf was unfolded (BBCH 16; PHI = 169 day), i.e. at an early growth stage. In another experiment, one cotton plant was treated two times, one time at an actual application rate of 209 g a.s./ha at BBCH 15 and a second time at an application rate of 176 g a.s./ha at 14 days before harvest of the cotton bolls (BBCH 95-97). The actual application rate of 385 g a.s./ha was slightly below the target rate of 400 g a.s./ha, which corresponds to the anticipated maximum application rate, which is maximally 410 g as/ha, as part of the Global Joint Review of flupyradifurone.. The cotton plants were cultivated by sowing cotton seeds in a soil “Einheitserde T” (85% white moor peat, 15% clay, pH=5.8) in planting pots with a surface area of 0.076 m^2 (1 plant/pot; i.e. approx.13 plants/m^2) and a volume of 15L. The plants were grown in a greenhouse.

Samples were taken at maturity of the seeds in both experiments from cotton seeds (which represent the edible RAC): 179 g (from 4 plants, single treatment) and 51 g (from 1 plant, double treatment); gin trash (1.1 and 0.19 kg, resp.) and lint (135 and 39 g, resp.). Additionally, one plant (31 g) of the single application experiment was sampled at an intermediate growth stage (DAT=28, at BBCH 22-24: two to four vegetative side shoots were visible) to support the identification of metabolites.

The radioactive residues were extracted three times with acetonitrile/water mixtures (8:2). In the case of seeds, the samples were extracted with heptane beforehand. For gin trash, additional exhaustive extraction steps were applied to the solids of the first extraction, comprising of two extraction steps with acetonitrile/water mixtures at 120 °C under microwave assistance. The radioactivity in the extracts was determined by LSC and in the solids by combustion followed by LSC. The intermediate and the gin trash extracts were subjected to an SPE clean-up using a pre-conditioned SPE RP 18 cartridge, whereas the seed and lint extracts were directly analyses by reversed phase HPLC, coupled to a radioactivity detector with a glass scintillator cell.The profiles of the extracts comprising a

reasonable amount of radioactivity were recorded by HPLC and all major and several minor components were identified. Identification of parent compound and metabolites common to both radiolabels was based on the metabolite profiles obtained in the cotton metabolism study with [pyridinylmethyl-^{14}C]flupyradifurone. In this study parent compound and the major metabolites were identified in at least one matrix either by LC-MS/MS after semi-preparative isolation of the compounds or by HPLC and TLC co-chromatography with authentic reference compounds. All assignments made in the present study were confirmed by HPLC co-chromatography in gin trash using authentic reference compounds.

The compounds BYI 02960-OH-glyc (M8) and BYI 02960-acetic acid (M15) co-eluted when using the neutral HPLC method for metabolite profiling. Therefore, the fraction was isolated from the gin trash extracts and was re-analysed with an acidic mobile phase. Both compounds were well separated using the acidic method and identification of both compounds became feasible by either HPLC co-chromatography with an authentic reference compound (BYI 02960-OH-glyc) or by LC-MS/MS (BYI 02960-acetic acid). The authentic reference compound used for co-chromatography was a metabolite isolated and identified in the apple metabolism study. The hexose in the conjugate was unambiguously assigned to D-glucose and the hydroxy group was located in the 5-position of the molecule. All assignments made were confirmed by HPLC co-chromatography in gin trash using authentic reference compounds. Assignment in the other matrices was performed by comparison of HPLC profiles since the metabolite profiles of all matrices were well comparable. No label-specific metabolite was identified.

Results

The TRR levels were 0.013 and 0.016 mg/kg in seeds, 0.19 and 2.8 mg/kg in gin trash, and <0.01 and 5.0 mg/kg in lint, in single and double application experiment respectively. The high residues were expected in gin trash and lint in the double application experiment, where the last treatment was performed 14 days before harvest when more than 90% of the cotton bolls were open. TRR in intermediate plant (single treatment) was 12 mg/kg. Due to the negligible residues, lint of the single application experiment was not subjected to extraction. The extracts of seeds (23% and 57% of 0.013 and 0.016 mg/kg for single and double application experiments respectively) were not further analyzed by HPLC due to the low radioactive residue levels (<0.01 mg/kg). Extraction efficiencies in lint, intermediate and gin trash ranged from 80% of the TRR for gin trash (single application experiment) to 97% for lint (double application experiment).

In total, 70 to 86% of the TRR in the matrices could be identified. Parent compound was the most prominent component, even in the single application experiment, and represented 38-70% of the TRR in all matrices analysed (lint, gin trash and intermediate). The sum of metabolites BYI 02960-OH-glyc (M8) and BYI 02960-acetic acid (M15) represented another major fraction in all matrices and accounted for 13-25% of the TRR; in gin trash BYI 02960-acetic acid represented 58% and 94% of the

combined M8 and M15 fraction in the single and double application experiment, respectively. Besides parent compound, M8 and M15, one additional major compound was detected only in gin trash: BYI 02960-OH (M3), representing 12% of the TRR in the single application experiment. All other metabolites detected in gin trash, lint and as well in the intermediate plant were minor or trace components (<10% of the TRR) in both single and double application experiments. Three of the minor metabolites were identified in gin trash: BYI 02960-glyoxylic acid (M17), BYI 02960-acetic acid-glyc (M16) and BYI 02960-bromo (M2) (probably co-eluting with small amounts of BYI 02960-chloro (M1)).

The TRR values of all plant matrices determined are shown in Table 7.1.1-13 and 7.1.1-14.

Conclusions

Metabolism of [furanone-4-^{14}C]-flupyradifurone was moderate in cotton. The residues were dominated by parent compound in both the single and double application experiments. Cotton gin trash was the matrix showing the highest number of metabolites.

The following metabolic routes of [furanone-4-^{14}C]BYI 02960 were observed in cotton:

- hydroxylation of the methylene group of the furanone moiety followed by conjugation
- oxidative opening of the furanone moiety to an acetic acid group followed by further oxidation or conjugation with a carbohydrate (e.g. glycosylation), and
- halogenation (mostly bromination, to a minor extent chlorination) of the furanone moiety

Halogenation of the furanone moiety of the active substance probably occurred in the soil which was supported by the fact that small amounts of halogenated parent compound were identified in the aerobic soil degradation studies. Due to the early timing of the first application, a significant portion of the parent compound could have reached the soil and been subjected to soil metabolism processes. On the basis of these results, a metabolic pathway of [furanone-4-^{14}C]flupyradifurone in cotton can be proposed (Figure 7.1.1-9).

Figure 7.1.1-9 Proposed metabolic pathway of [furanone-4-^{14}C]BYI 02960 in cotton

Guidelines & Limitations

The level of extraction, identification and characterisation of radioactivity in cottton is sufficient. The study results are acceptable.

Guideline	:	OECD 501, OPPTS 860.1300, PMRA Dir 98-02, Japanese MAFF, 12 Nousan 8147	Acceptability	:	acceptable

Study design

The study design is the same as described in study 8 (Schmeling and Weber 2011a), with the following changes:

- The radiolabel used is: [pyridinylmethyl-^{14}C]flupyradifurone with a specific radioactivity of 118 µCi/mg and radiochemical purity >98%.
- Application rates were slightly different, i.e. the application rate was 206 g a.s./ha (in stead of 209 g a.s./ha), at the first treatment in both experiments (at BBCH=16), and 177 g a.s./ha (in stead of 176 g a.s./ha) at the second treatment (double application experiment only), 15 days before harvest.
- Weight of harvested intermediate was 41 g (1 plant, single application), weight of gin trash: 0.96 and 0.18 kg; of lint: 146 and 46 g; and of seeds: 213 and 60 g, from 4 and 1 plant(s) in single and double application experiments, respectively.

Parent compound and major metabolites were identified either by HPLC and TLC co-chromatography (two independent chromatographic systems) or by mass spectroscopic means (LC-MS/MS) in the gin trash extracts. Minor compounds were assigned by comparison with the corresponding profiles of the cotton metabolism study with [furanone-4-^{14}C]BYI 02960.

Results

The TRR levels were 0.045 and 0.068 mg/kg in seeds, 0.31 and 2.3 mg/kg in gin trash, and <0.01 and 8.8 mg/kg in lint, in single and double application experiments, respectively. TRR in intermediate plant (single treatment) was 14 mg/kg. Due to the negligible residues, lint of the single application experiment was not subjected to extraction. Extraction efficiencies ranged from 28% of the TRR for seeds (single application experiment) to 99% for lint (double application experiment).

In total, 16 to 90% of the TRR could be identified. Parent compound was the most prominent component in all matrices, except for seeds of the single application experiment, and accounted for 23% to 73% of the TRR. The labelspecific 6 CNA (M27) was the main (and only) compound identified in seeds of the single application experiment (16% of TRR), and was also found in all other cotton matrices. Additional major metabolites detected in cotton matrices were BYI 02960-OH (M3) (gin trash only), and the sum of co-eluting compounds BYI 02960-OH-glyc (M8) and BYI 02960-acetic acid (M15). Separation of the co-eluting compounds revealed that M15 represented approx. 67% of the fraction in gin trash in the single application experiment and approx. 94% of the fraction in the double application experiment. All other metabolites detected in cotton matrices represented minor or trace components (<10% of the TRR) in both single and double application experiments. Three of the minor metabolites were identified in gin trash: BYI 02960-glyoxylic acid (M17), BYI 02960-acetic acid-glyc (M16) and BYI 02960-bromo (M2) (probably co-eluting with small amounts of BYI 02960-chloro (M1)).

The TRR values of all plant matrices determined are shown in Table 7.1.1-15 and 7.1.1-16.

Conclusions

Gin trash showed the highest number of metabolites along with the intermediate. It was shown that the metabolite profiles of all matrices were compatible with those obtained in the cotton metabolism study conducted with [furanone-4-^{14}C]flupyradifurone.

In seeds of the single application experiment, 6-CNA (M27) was identified as main compound. This finding corresponds with the known fact that weak acids tend to have good phloem mobility and are therefore transported selectively into the seeds as a phloem sink. Initial formation of 6-CNA took most probably place in the leaves, which is in line with the finding that 6-CNA is also the main metabolite detected in gin trash. 6-CNA was also detected in the seeds of the double application experiment,

however quite high amounts of parent compound and the co-eluting compounds BYI 02960-OH-glyc (M8) and BYI 02960-acetic acid (M15) superposed the 6-CNA amounts. Most probably the high amounts of these compounds were caused by contamination of the seeds by lint residues, as in the cotton bolls (capsules) the seeds are imbedded in the lint. As seeds are still covered by lint fibres, it is not uncommon to detect the major residues of lint as well in the seed extract. Since lint showed only high residues in the double application experiment, interfering residues were only detected in seeds of this experiment.

Figure 7.1.1-10 Proposed metabolic pathway of [pyridinylmethyl-^{14}C]BYI 02960 in cotton

Guidelines & Limitations

The level of extraction, identification and characterisation of radioactivity in cottton is sufficient. The study results are acceptable.

Overall Conclusions Cotton (foliar application)

The metabolism of flupyradifurone was investigated in the raw agricultural commodities cotton seeds and gin trash and as well in lint following two different spray application scenarios of furanone- or pyridinylmethyl-labelled flupyradifurone. In the single spray application experiment, cotton plants were treated once at PHI 169 day. In the double spray application experiment, one plant was treated at the early growth stage and additionally 14 days before harvest. The target rate per application in both

experiments was 200 g a.s./ha. In order to gain information on the fate of the difluoroethane moiety, the extracts obtained in the cotton metabolism study with pyridinylmethyl-labelled flupyradifurone were additionally analysed for non-radiolabelled difluoroacetic acid by LC-MS/MS according to residue method 01304 (see study 12).

As expected, the residues in the double spray application experiments were dominated by parent compound (at least 25% of TRR). However, even in the single spray applications, parent compound was the main residue (at least 23%) in all cotton matrices analysed, except for seeds (edible commodity). In seeds, 6-CNA (M27)was identified as the only prominent compound with pyridinylmethyl-labelled flupyradifurone; in furone-labelled flupyradifurone, residues in seeds were too low (<0.02 mg/kg) to analyse in both single and double treated cotton plants. Besides parent compound, BYI 02960-acetic acid (M15), BYI 02960-OH-glyc (M8), 6-CNA (M27) and BYI 02960-OH (M3, only gin trash and intermediate) were major metabolites detected in the different matrices. All other metabolites represented less than 10% of the TRR in all matrices.

Analysis of cotton seed and gin trash extracts on the non-radiolabelled metabolite difluoroacetic acid revealed that this metabolite represents a significant proportion of the residues in the single and double application experiments. Difluoroacetic acid accounted for 0.09 mg a.s. equiv./kg (0.03 mg/kg DFA) and 0.06 mg a.s. equiv./kg (0.02 mg/kg DFA) in cotton seeds in the single and the double application experiment and thus represents by far the main proportion of the residues. These findings support the assumption that difluoroacetic acid has a pronounced phloem mobility and is therefore transported selectively into the seeds as a phloem sink. In gin trash, difluoroacetic acid accounted for 0.12 mg a.s. equiv./kg (0.04 mg/kg DFA) in the single application experiment and exceeded the concentration of parent compound. In the double application experiment, parent compound and several metabolites showed higher concentrations than difluoroacetic acid due to the short PHI of the last application.

When considering the results from both metabolism studies conducted on cotton, it can be concluded that flupyradifurone is rather extensively metabolised in this crop. A total of 4 major and approx. 15 minor metabolites were found, and all major and 3 minor have been identified. The edible commodity cotton seed showed only very low radioactive residues and analysis of the extracts was only feasible in the study conducted with the pyridinylmethyl-label. The distribution of parent compound and metabolites in the edible commodity seeds is shown in Table 7.1.1-17; the distribution in the feed commodity gin trash is summarised in Table 7.1.1-18.

Remark:

The metabolite profile of cotton seeds from the double application experiment shows most probably an interference from the lint profile since undelinted seeds were analysed.

On basis of the metabolites identified, biotransformation of flupyradifurone in cotton proceeds by the following pathways:

- oxidative cleavage of the difluoroethylamine bond and formation of difluoroacetic acid
- oxidative degradation of the furanone moiety to an acetic acid group followed either by conjugation with a carbohydrate or by further oxidation to BYI 02960-glyoxylic acid
- oxidative cleavage of the pyridinylmethylamine bond and formation of 6-CNA
- hydroxylation of the furanone moiety followed by conjugation with glucose
- halogenation (bromination and most probably chlorination, as well) of the furanone moiety

Halogenation of the furanone moiety of the active substance probably occurred in the soil which is supported by the fact that small amounts of halogenated parent compound were identified in the aerobic soil degradation studies. Due to the early timing of the first application, a significant portion of the parent compound could have reached the soil and been subjected to soil metabolism processes.

The positions involved in the metabolic degradation are summarised in Figure 7.1.1-10.

Figure 7.1.1-10: Positions involved in metabolic degradation of flupyradifurone in cotton matrices

Study design

The metabolism of flupyradifurone was investigated in paddy rice (*Oryza sativa L.* variety: Nihonbare) according to the maximum envisaged use pattern according to the notifier. Two different methods of application were covered in this study. One experiment was a granule treatment (GR) with [furanone-4-^{14}C]BYI 02960 (specific radioactivity: 106 µCi/mg; radiochemical purity >99%) applied during the transplanting of the rice seedlings at an application rate of 409 g a.s./ha. The granules were distributed equally in the planting holes directly before the seedlings (BBCH 13-15) were transplanted into the holes. Then the planting container was flooded with water. In the second experiment, the furanone-labelled flupyradifurone was formulated as an SL 200 and applied twice as spray treatment (SP) equally onto plants as well as the water surface; the first spray application took place directly after transplanting of the rice seedlings at a rate of 175 g a.s./ha and the second 29 days before harvest at a rate of 240 g a.s./ha.

The rice plants were cultivated in sandy loam soil with a pH of 6.8, in a planting container with a surface area of 0.5 m^2. The plants were cultivated in a climate chamber in a greenhouse. Rice was harvested at maturity (BBCH 89-92) and plantparts devided in kernels (31and 85 g), husks (21and 46 g) and straw (328 and 360 g, GR and SP respectively). All plant parts were dried at room temperature for five days. The homogenized samples of kernels, husks and straw were stored in a freezer (≤ -18°C) until analysis.

The radioactive residues were extracted three times with acetonitrile/water mixtures (8:2). The post-extraction solids (PES) of kernels and straw were subjected to an exhaustive extraction procedure. The solids were extracted with acetonitrile/water mixtures (8:2 and 1:1) at 120 °C for 15 min. under microwave assistance. Remaining solids of rice kernels were subjected to an additional third microwave extraction step with sodium chloride/water (1:99; w/v); kernels from the spray treatment were further subjected to a diastase treatment (pH 5, 26 °C, 20 h) The radioactivity in the extracts was determined by LSC and in the solids by combustion followed by LSC. The extracts of the sample materials husks and straw were subjected to a clean-up step using a pre-conditioned SPE RP 18 cartridge, whereas the kernel extracts were directly analyses by reversed phase HPLC, coupled to a

radioactivity detector with a glass scintillator cell.The profiles of the extracts comprising a reasonable amount of radioactivity were recorded by HPLC and all major and several minor components were identified. Identification of parent compound and metabolites common to both radiolabels was based on the metabolite profiles obtained in the rice metabolism study with [pyridinylmethyl-^{14}C]flupyra-difurone. In this study parent compound and all metabolites common to both radiolabels were identified by LC-MS/MS after semi-preparative isolation of the compounds or by HPLC co-chromatography with authentic reference compounds. Thus assignment of compounds in the present study was possible by comparing the metabolite profiles. Some of the assignments were confirmed by HPLC co-chromatography using authentic reference compounds. The only label-specific metabolite detected was identified by TLC co-chromatography with the polar fraction isolated and identified in the tomato metabolism study. Additionally, two non-polar metabolites were identified by LC-MS/MS after isolation of the compounds.

Results

The TRR levels were 0.14 and 0.66 mg/kg in kernels, 1.4 and 24 mg/kg in husks, and 2.9 and 20 mg/kg in straw, in single and double application experiment respectively. Extraction efficiencies ranged from 69% of the TRR for kernels (GR) to 94% for straw (SP) after exhaustive extraction. In total, 50 to 86% of the TRR in the matrices could be identified. Parent compound was the most prominent component, even in the single application experiment, and represented 23-75% of the TRR in all matrices. Glucose/carbohydrates (M45) was also detected as major metabolite in kernels (GR) and represented 27% of the TRR. Metabolite BYI 02960-chloro/bromo was detected as a major metabolite in straw after granular (GR) and spray treatment (SP) and accounted for approx. 11% of the TRR. Halogenation of the furanone moiety of the active substance probably occurred in the paddy soil. Soil contact with parent compound resulted in both experiments. All other detected metabolites were minor or trace components, including BYI 02960-acetic acid (M15), BYI 02960-glyoxylic acid (M17), and BYI 02960-OH (M3).

The TRR values of all plant matrices determined are shown in Table 7.1.1-19 and 7.1.1-20.

Conclusion

[Furanone-4-^{14}C]flupyradifurone was metabolised moderately in paddy rice. Parent compound was the most prominent component and represented approx. 23 – 75% of the TRR in all matrices.

The following metabolic routes of [Furanone-4-^{14}C]flupyradifurone were observed in paddy rice:

- halogenation (mostly bromination, to a minor extent chlorination) of the furanone moiety,
- hydroxylation of the methylene group of the furanone moiety,

- oxidative opening of the furanone moiety to an acetic acid group followed by further oxidation or conjugation with a carbohydrate (i.e. glycosylation), and
- complete degradation of the furanone moiety and incorporation of the carbon atoms into the natural compound pool, i.e. into glucose/carbohydrates

On the basis of the results of this study it is concluded that the metabolism of furanone-labelled flupyradifurone in rice is well understood and the following metabolic pathway is proposed.

Figure 7.1.1.-11 Proposed metabolic pathway of [furanone-4-^{14}C]flupyradifurone in rice

Study design

The study design is the same as described in study 10 (Schmeling, S. 2011c), with the following changes:

- The radiolabel used is: [pyridinylmethyl-^{14}C]flupyradifurone, with a specific radioactivity of 118 µCi/mg and radiochemical purity >98%.
- Application rates were slightly different, i.e. in stead of 409 g a.s./ha the application rate was 434 g a.s./ha at the granular treatment), and 178 and 236 g a.s./ha in the second treatment (double application experiment only).

Identification and characterisation

Identification of parent compound, the only major metabolite, and the next most prominent metabolite was performed by mass spectrometry after isolation of the compounds from the rice straw extract after spray application. Assignment of the compounds in other matrices was performed by HPLC co-chromatography or by comparison of the HPLC profiles. Additionally, four minor metabolites were identified in rice straw by HPLC co-chromatography using authentic reference compounds.

Results

Sample weight were 71 and 89 g for kernels, 41 and 43 g for husks and 386 and 344 g for straw, in single and double application experiment, respectively; TRR levels were 0.050 and 0.62 mg/kg in kernels, 1.6 and 24 mg/kg in husks, and 3.3 and 25 mg/kg in straw, respectively. Extraction efficiencies ranged from 74 to 97% after exhaustive extraction. In total, 74 to 89% of the TRR in the matrices could be identified. Parent compound was the most prominent component, even in the single application experiment, and represented 60-78% of the TRR in all matrices. One major metabolite (>10% of the TRR) was detected only in rice straw from the granular experiment. The metabolite was identified as BYI-bromo by LC-MS/MS. No other major metabolites were detected. MInor or trace components detected included BYI 02960-acetic acid (M15), 6-CNA (M27), BYI 02960-glyoxylic acid (M17), BYI 02960-acetic acid-glyc (M16), and BYI 02960-OH (M3). The TRR values of all plant matrices determined are shown in Table 7.1.1-21 and 7.1.1-22.

Conclusions

[Pyridinylmethyl-^{14}C]BYI 02960 is metabolised moderately in rice. Residues were dominated by parent compound in the foliar application experiment, and parent compound was also the main compound in all matrices of rice after granule application. In total, seven different metabolites were identified in rice straw, which shows the most pronounced metabolite pattern. Only one of these metabolites, the halogenated parent compound, represented more than 10% of the TRR (approx. 12%).

Generally, four major metabolic routes of pyridinylmethyl-labelled flupyradifurone were observed in rice:

- hydroxylation of the methylene group of the furanone moiety,
- cleavage of the pyridinylmethylamine bond followed by oxidation of the methylene group to 6-CNA,
- oxidative degradation of the furanone moiety to an acetic acid group followed by either conjugation with a carbohydrate or further oxidation, and
- halogenation (mostly bromination, to a minor extent chlorination) of the furanone moiety,

It is considered likely that halogenation of the furanone moiety of the active substance occurred in the paddy soil/sediment. On the basis of the results of this study it is concluded that the metabolism of pyridinylmethyl-labelled flupyradifurone in rice is well understood and the following metabolic pathway is proposed.

Figure 7.1.1-12: Proposed metabolic pathway of [pyridinylmethyl-^{14}C]BYI 02960 in rice

Guidelines & Limitations

The level of extraction, identification and characterisation of radioactivity in paddy rice is sufficient. The study results are acceptable.

Overall Conclusions Rice (foliar and granule application)

The metabolism of the flupyradifurone was investigated in rice kernels, straw and husks following two different application scenarios of furanone- or pyridinylmethyl-labelled flupyradifurone. In a granule application experiment, rice was treated once at transplanting of the plants (BBCH 13-15), and in a spray application experiment, the plants were treated at transplanting and additionally 30 days before harvest. The total target application rate in both experiments was 400 g a.s./ha. Regardless of the application rate, the TRR values in all rice matrices were significant lower after the granule application compared to the foliar application. As expected, the residues in the spray application experiments were dominated by parent compound in both studies. But, even after the early granule application, parent compound was the main residue in rice husks and straw and, if not the main, a prominent residue in kernels.
Subsequent analysis of the extracts on the non-radiolabelled metabolite difluoroacetic acid – which cannot be detected with the radiolabels used – confirmed that parent compound represented always the highest proportion of the residue, except for rice kernels after granular application, where difluoroacetic acid was the main constituent (see study 12).

The lowest residue levels were detected in rice kernels, irrespective from the application scenario. After granule application in the furanone-label experiment, the main residue in rice kernels was represented by a natural compound (glucose/carbohydrates), indicating a quite intense degradation of the furanone moiety, whereas parent compound was the main compound after spray application, and in both experiments with the pyridinylmethyl-label.

The residue levels in straw and husks were significantly higher (by a factor of 10 to 66), but the metabolite patterns were very comparable for all matrices in both experiments. Besides parent compound or glucose, an additional major metabolite (>10% of the TRR) was detected with both labels but only in rice straw: BYI 02960-bromo, co-eluting with small amounts of BYI 02960-chloro. These halogenated metabolites were most likely not formed in the plants, but in the paddy soil/sediment and taken up by the plants.
In total, four additional minor metabolites were identified, but none of them exceeded 8% of the TRR. Overall, five major metabolic routes were detected: (1) Oxidative degradation of the furanone moiety to an acetic acid group followed by further oxidation or conjugation with a carbohydrate, (2) complete degradation of the furanone moiety and incorporation of carbon atoms into the natural compound pool, i.e. into glucose/carbohydrates; (3) cleavage of the pyridinylmethylamine bond followed by oxidation of the methylene group to 6-CNA; (4) hydroxylation of the furanone moiety of the parent compound and (5) halogenation (bromination, to a minor extent chlorination) of the furanone moiety, which probably occurred in the paddy soil/sediment. Only the second (only determined with furanone-label) and third route (only determined with pyridinylmethyl-label) led to a label-specific metabolite, which were each others counterpart. The concentrations of the metabolites common to both radiolabels tested

correspond very well when comparing the two metabolism studies conducted in rice.

When considering the results from both metabolism studies conducted in rice, it can be concluded that flupyradifurone is rather extensively metabolised in this crop. A total of 3 major and approx. 25 minor metabolites were found, and all major and 5 minor have been identified. The edible commodity rice kernel showed low radioactive residues, especially after granule application. The distribution of parent compound and metabolites in the edible commodity rice kernels is shown in Table 7.1.1-23.

Analysis of the extracts of rice kernels and the feed items husk and straw on the non-radiolabelled metabolite difluoroacetic acid revealed that this metabolite represents a significant proportion of the residues in rice kernels after granule and spray application and in husks and straw after granule application (see study 12). It is also detected in rice husks and straw after spray application, but only as minor metabolite. Difluoroacetic acid accounted for 0.06 and 0.24 mg a.s. equiv./kg in rice kernel after granule application and after spray application, respectively. These findings support the assumption that difluoroacetic acid has a pronounced phloem mobility and is therefore transported selectively into the seeds as a phloem sink. In rice straw and husks, the difluoroacetic acid concentrations ranged between 0.36 mg/kg and 1.4 mg/kg. Generally, higher concentrations of difluoroacetic acid were detected after spray application.

On basis of the metabolites identified, biotransformation of flupyradifurone in rice proceeds by the following pathways:

- oxidative cleavage of the difluoroethylamine bond and formation of difluoroacetic acid
- oxidative degradation of the furanone moiety to an acetic acid group followed either by conjugation with a carbohydrate or by further oxidation to BYI 02960-glyoxylic acid
- complete degradation of the furanone moiety and incorporation of carbon atoms into the natural compound pool, e.g. into glucose/carbohydrates
- oxidative cleavage of the pyridinylmethylamine bond and formation of 6-chloronicotinic acid (6-CNA)
- hydroxylation of the furanone moiety
- halogenation (bromination and most probably chlorination, as well) of the furanone moiety

It is considered likely that halogenation of the furanone moiety of the active substance occurred in the paddy soil/sediment. Uptake of the soil metabolite results in plant residues. The positions involved in the metabolic degradation are summarised in the following figure.

Figure 7.1.1-13: Positions involved in metabolic degradation of flupyradifurone in rice matrices

Study design

Residues of non-radiolabelled difluoroacetic acid, the most plausible metabolite that can be formed from the difluoroethane moiety due to cleavage of BYI 02960, were determined in extracts of samples of apples, potatoes, cotton, rice, wheat, Swiss chard and turnips originating from plant metabolism and confined rotational crops studies after application of [pyridinylmethyl-^{14}C]BYI 02960 or [furanone-4-^{14}C]BYI 02960. To estimate the residue levels of difluoroacetic acid in these crop samples, non-radiolabelled difluoroacetic acid was analyzed according to the provisions of residue analytical method 01304.

Results

The residue levels determined in the samples from the different metabolism studies are summarized in the following tables. The residues are expressed as difluoroacetic acid equivalents.

Table 7.1.1-24: Summary of difluoroacetic acid residues in crop matrices after spray application of flupyradifurone

Conclusions

Significant levels of difluoroacetic acid (DFA) were detected in most of the primary and confined rotational crops under investigation irrespective of the application technique. High difluoroacetic acid concentrations after foliar spray application indicate that this metabolite is also formed in plants and not only in soil.

Guidelines & Limitations

The study is acceptable to address the residue levels of difluoroacetic acid in primary and rotational crops.

Study 13

Reference	:	Thielert, Schoening, 2012; KIIA 6.10/01	Application rate	:	-
Type of study	:	-	Total rate	:	-
Year of execution	:	2012	Area	:	-
Test substance	:	Flupyradifurone	Plant	:	Tomato, melon, cucumber
GLP statement	:	Yes	Sampling	:	-
Guideline	:	none	Acceptability	:	acceptable

Study design

Translocation experiments were performed by applying flupyradifurone parent labelled at the [pyridinylmethyl-^{14}C] and [ethyl-1-^{14}C] moiety of the molecule to fruiting vegetables grown in greenhouses. Plant parts were dried and analysed by a Fuji-Fujix BAS Cassette 2040 phosphor imager.

Application of [pyridinylmethyl-^{14}C]flupyradifurone to soil of tomato and melon plants

[pyridinylmethyl-^{14}C]flupyradifurone SL 200 was applied by droplet application on midribs of pinnate leaves, leaf lamina of 2 centre pinnate leaves and main stem above leaf 8 on tomato plants (variety Rentita).

Plant Samples were taken 1DAT and 4 DAT. Results are summarised in Table C7.1.1-25. An example autoradiograph is given in figure 7.1.1-14

Table 7.1.1-25: Results of the translocation experiments with [pyridinylmethyl-^{14}C]flupyradifurone in tomato plants

Dose	Location of application Spot	Translocation to	
		1DAT	4DAT
10 µl (0.33mg, 25kBq)	On Center midrib of leaf 7	Pinnate leaf adjacent to drop	Pinnate leaves adjacent and above drop
2x 5µl (0.16mg, x 1 kBq)	On either sides of midrib of pinnate leave of leaf 8	Pinnate leaf adjacent to drop	-
10 µl (0.33g, 25kBq)	On stem above leaf 8	In leaves 9 and 10	In leave 9 and 10 but not in newly formed top leaf 11
Conclusion from autoradiographs:	Flupyradifurone residues are found 'upstream' of the application spots and it is conclude that it is transported by xylem.		

Figure 7.1.1-14: **autoradiograph of potato plant 4 days after application of 0.33 mg (25kBq) [pyridinylmethyl-^{14}C]flupyradifurone above leave 8. After 4 days, radioactive residues were found in the upstream leaves present at the time of application but not in the newly formed top leaves.**

Application of [pyridinylmethyl-^{14}C]flupyradifurone to soil of tomato plants

Plants were drenched with 50 mL containing 24 mg flupyradifurone per plant labelled with 312kBq [pyridinylmethyl-^{14}C]flupyradifurone.

Figure 7.1.1-15: **Autoradiograph of tomato shoots 1, 3, 7, 14 and 24 days after application of 0.24 mg (312kBq) [pyridinylmethyl-^{14}C]-flupyradifurone per plant to the soil.**

Residues of flupyradifurone were rapidly taken up via the root system into tomato plants and translocated within 1-24 days after treatment in the direction of the transpiration stream into the shoot followed by a translaminar distribution into the leaves. Over time, radiolabelled compounds accumulated at the leaf margins while leaf laminae were gradually depleted. It is concluded that flupyradifurone and its metabolites are transported by xylem very well (Figure 7.1.1-15).

Application of [pyridinylmethyl-^{14}C]flupyradifurone to soil of melon plants

Plants were drenched with 50 mL containing 36 mg flupyradifurone per plant labelled with 322kBq [pyridinylmethyl-^{14}C]flupyradifurone.

Figure 7.1.1-16: **Autoradiograph of melon shoots 31 days after application of 0.36 mg (322kBq) [pyridinylmethyl-14C]flupyradifurone to the soil.**

White arrows: location of flowers

Radiolabelled flupyradifurone and its metabolites were taken up via the root system into cantaloupe plants and were translocated via the xylem in the direction of the transpiration stream into the shoot followed by a translaminar distribution into leaves and flowers. Over time (31DAT), radiolabelled compounds accumulated at the leaf margins while leaf laminae were gradually depleted (Figure 7.1.1-16).

Application of [ethyl-1-^{14}C]flupyradifurone to cucumber shoots

Radioactive residues of flupyradifurone (and metabolites) showed a rapid acropetal uptake of radiolabelled compounds into the plant and translocation within 1-14 days after treatment mainly via the xylem in direction of the transpiration stream and a translaminar distribution into adjacent plant cells, irrespective of the application point. Radioactivity accumulated at the leaf margins over time. Autoradiographs indicated also a translocation of radioactive compounds from treatment points on leaf 4 and leaf axil 4 via the phloem into plant parts below and above the application points, i.e. leaves, stems, petioles, tendrils, flowers and fruitlets.

Table 7.1.1-26: Results of the translocation experiments with [ethyl-1-^{14}C]flupyradifurone in cucumber plants.

Dose	Location of application Spot	1DAT	7DAT	14DAT
1 x 25kBq/6mg	Leaf axil of leaf 4	Main transport into leaf lamina 4. Limited transport to leaf 3 and leaf 5, 6.	Limited transport to leaf 3, 5-10. Transport into leaf lamina 4.	Limited transport to leaf 3, 7, especially the leaf margins. Moderate transport to leaf 5 including side shoot, flowers and fruits. Moderate transport to shoots of leaf 3 High transport from leaf lamina 4 to the leaf margins
2 x 25kBq/6mg	On either sides of midrib of pinnate leave of leave 4	Main transport into laminae of leaf 4. Limited transport to leaf 5,6,7,8	Main transport into margins of laminae of leaf 4. Limited transport to axil of leaf 4 and underlying leaf 3 and leaves 5, 6, 7, 8	Transport into leaf veins, margins of lamina and petiole of leaf 4. Limited transport to leaf 3, 5, 6, 7, 8, 9, 10, 11.
Conclusion from autoradiographs:		Flupyradifurone and/or metabolites are directly transported 'upstream' of the application spots and it is conclude that it is transported by xylem. Later on, flupyradifurone and/or metabolites are also found to be transported in leaves below the application spot and it is concluded that it can be transported by phloem as well.		

Determination of BYI02960, DFEAF, DFA and nictotinoic acid in cucumber shoots

Unlabelled flupuradifurone was applied to cucumber plants 2 times in a dose of 7.8 mg per plant per meter canopy height. Plants were divided in levels (from top to root, see figure at right):

- Leaf level 6-10 (untreated leaves 6-10)
- Leaf level 1-5 (treated leaves 1-5)
- Leaf level 0 (untreated leaves).

Application interval was 10 days, with the last application 3, 7, 14 and 28 days before harvest.

Residues of flupyradifurone parent (BYI 02960) and its metabolites difluoroacetic acid (DFA), BYI 02960-difluoroethyl-amino-furanone (DFEAF) and 6-chloronicotinic acid (6-CNA), each analyte expressed as parent, were determined by LC-MS/MS according to method 01304.

Residues have been determined in treated leaves (level 1-5), untreated leaves below (level 0) and untreated leaves and fruit above the application zone (level 6-10). Results are tabulated in Tables 7.1.1-27 to 7.1.1-33. Positive residues are marked in bold.

1. Flupyradifurone could almost not be found translocated out of treated leaves containing between 8.8-42 mg flupyradifurone/kg into untreated cucumbers within 3-28 days after application. Only in 3 out of 54 analyzed cucumbers from different plants minute amounts of flupyradifurone ranging between 0.01-0.04 mg/kg cucumber fresh weight were detected 3-28 days after application. Peak concentrations were measured in treated leaves 3 days after application. The low percentage of cucumbers (5.6% out of 54 cucumbers) containing amounts of parent compound close to the LOQ presumably due to a contamination during the application.
2. DFEAF could not be detected in any of the cucumbers analyzed although it was detected in treated leaves at concentrations ranging between 0.08-0.31 mg DFEAF/kg leaf fresh weight. Peak concentrations in treated leaves were detected 7 days after application.
3. DFA was formed in treated leaves at concentrations between 2.1-11 mg per kg leaf fresh weight and translocated via the phloem into cucumbers growing in adjacent leaf axils of treated leaves at a range of 0.06-0.80 mg DFA/kg cucumber fresh weight. Even in cucumbers growing in leaf axils of untreated leaf zones between 0.03-0.54 mg DFA/kg cucumber fresh weight were found. Peak concentrations were reached 21 and 28 days after application, respectively.
4. 6-CNA was found only in 4 out of 54 cucumbers in low amounts (0.02 mg/kg fresh weight) 14 days after application close to the LOQ (0.01 mg/kg fresh weight). In treated leaves, however, 6-CNA reached concentrations between 0.33-2.4 mg/kg leaf fresh weight, peaking 7 days after application.

Conclusions on systemicity

The authors refer to Bromilow et al. (1991) and Rocher et al. (2006) who described a model for xylem and phloem transport based on the physico-chemical properties (water solubility and ionization state of acids, pKa and fat solubility, log Kow) of substances. The systemic behaviour of [pyridinylmethyl-^{14}C]flupyradifurone, [ethyl-1-^{14}C]flupyradifurone and non-labelled flupyradifurone, DFA, DFEAF and 6-CNA after foliar and soil drench application in tomato, melon and cucumber plants correspond well with this model.

	Flupyradifurone ★	6-CNA ★	DFA ★	DFEAF ★
pKa	neutral at 2-12	3.24	1.1	neutral at 2-12
log Kow	1.2	1.15	-3.1/-3.5	-0.2

Flupyradifurone (neutral, log Kow = 1.2) was mainly translocated via the xylem apart from a few cucumbers where minute concentrations slightly above the LOQ were detected.

DFA (pKa = 1.1, Log Kow ~ -3.5) and 6-CNA (pKa = 3.24 and Log Kow = 1.15) can be retained in the phloem and translocated into basipetal and acropteal directions within a plant from a treated source to a growing sink.
Data suggest a distinct phloem transport of DFA which can lead to increasing concentrations into growing cucumbers and leaves. Theoretically, a higher proportion of 6-CNA was expected to be translocated via the phloem due to its more favourable physico-chemical properties regarding the model.

DFEAF (neutral, log Kow = -0.2) was translocated via the xylem only.

Guidelines & Limitations

The specially designed residue study to confirm the model predictions of Bromilow et al. on the basis of the physicochemical properties (log Kow and pKa confirmed the translocation behaviour and the systemicity) of the parent compound and its major metabolites.

B.7.1.2 Succeeding and rotational crops (IIA 6.6.2)

STUDY 1
Characteristics

Reference	:	Klempner, A.; 2011 KIIA 6.6.2/01	Application rate	:	436 g a.s./ha (1.75N)
Type of study	:	Metabolism in Rotational Crops	Area	:	planting container with a surface area of 1 m^2
Year of execution	:	2008-2011	Plant	:	wheat (cereal), Swiss chard (leafy vegetable) and turnips (root vegetable)
Test substance	:	[furanone-4-^{14}C] Flupyradifurone ; sample ID: KATH 6104; ; purity >99% w/w; batch code BYI 02960-PU-01; purity 99.9% w/w	Plant back intervals	:	29, 135 and 296 days
GLP statement	:	Yes	Acceptability	:	Acceptable

Description

Test material

Chemical structure	* position of the radiolabel
Radiolabelled test material	[furanone-4-^{14}C]BYI 02960
Specific radioactivity	3.97 MBq/mg (106.46 µCi/mg)
Chemical Purity	> 99% (HPLC)
Radiochemical purity	> 99% (HPLC and TLC)

Experimental conditions

The metabolism of flupyradifurone was investigated in the representative rotational crops wheat (cereal), Swiss chard (leafy vegetable) and turnips (root vegetable) from three consecutive rotations. [Furanone-4-^{14}C]BYI 02960 was formulated as an SL 300 and sprayed onto the bare soil of a planting container (approx. 1 m^2). The actual application rate corresponded to 436 g a.s./ha, above the anticipated maximum seasonal field rate of 250 g a.s./ha for EU uses (1.75N). The crops were each sown at 29, 135 and 296 days after the soil application, representing the first, second and third rotation.

Sampling

Intermediate raw agricultural commodities (RACs) investigated were Swiss chard immature (BBCH 44-46), wheat forage (at BBCH growth stage 29-31) and wheat hay (sampled at BBCH 79-83 and dried for five days). All other RACs (wheat straw, wheat grain, Swiss chard, turnip leaves and turnip roots) were harvested at maturity.

Extraction and quantification

An aliquot of each homogenized RAC was extracted conventionally three to four times with ACN/water (8:2, v/v). The extracts were combined, purified using a pre-conditioned SPE RP 18 cartridge, concentrated and analysed by HPLC. The radioactivity in the extracts was determined by LSC, in the solids by combustion followed by LSC. The actual TRR values of the samples were determined by summing up the radioactivity measured in the extracts and in the remaining solids.

Post-extraction solids of wheat straw from the 1st and 2nd rotation were subjected to a sequential extraction procedure after one exhaustive extraction step with ACN/water (8:2, v/v) at increased temperature (60 °C) under microwave conditions. The solids of the microwave extraction step were subjected to a treatment with sodium chloride solution (2 h at 100 °C under microwave assistance), a diastase incubation (approx. 20 h at 26 °C), a treatment with EDTA solution (3 h at 100 °C under microwave assistance) and a cellulase treatment (approx. 20 h at 40 °C) at adjusted temperatures to break down the plant cell walls and liberate residues bound to cell walls or in the cells. The remaining solids of the sequential extraction were extracted finally in two steps with a 5N HCl and a 5N NaOH solution (each 2 h at 100 °C). Extracts of the first three exhaustive extraction steps were concentrated and analysed separately by HPLC. Extracts of the EDTA, the cellulase and the HCl treatment were combined and adjusted to pH 7. The combined extract was concentrated, centrifuged and analysed by HPLC. The NaOH extract was not submitted to HPLC due to its high viscosity.

Post-extraction solids of grains from the 1st and the 2nd rotation were subjected to three subsequent exhaustive extraction steps: Microwave extraction with ACN/water at 100 °C followed by a digestion step with diastase (20 h at 26 °C) and subsequent microwave extraction with a sodium chloride solution (2 h at 100 °C). Only the first exhaustive extract was analysed by HPLC, the two following extracts were highly viscous due to a high matrix load and could not injected in the HPLC system. Therefore a further aliquot of the post extraction solids of grains from the 1st rotation was subjected to digestion with diastase over 14 days at ambient temperature. The residues in the diastase digestion solution were further characterized by partitioning against dichloromethane.

Identification and characterisation

Identification was achieved by spectroscopic evidence (LC-MS/MS) after isolation and purification of the respective compounds from the conventional extracts of wheat straw or Swiss chard of the 1st rotation. HPLC co-chromatography with the isolated and identified radiolabelled metabolites allowed

the assignment of the compounds in other extracts. The polar fraction detected in wheat grains was identified by TLC co-chromatography using the natural compound (glucose/carbohydrates) identified in the tomato metabolism study conducted with [furanone-4-^{14}C]BYI 02960, as reference compound. Other polar metabolites/fractions were also analysed by normal phase TLC.

Storage stability

All samples were conventionally extracted and analysed by HPLC within a few days after sampling. Quantitative ^{14}C-HPLC analysis of the extracts was performed with the profiling method BYI02960_NEUTR within one week after harvest. Only for wheat forage and hay, Swiss chard and turnips from the 1st rotation, the metabolic profile was measured with the preliminary profiling method BYI02960_CRC directly after extraction. For better comparison of metabolic pattern over all RACs of all rotations, the profiles of wheat forage and hay, Swiss chard and turnips of the 1st rotation were re-analysed with method BYI02960_NEUTR about 1 – 2 months after extract preparation. These new metabolic profiles were then considered as basis for quantification. Extract stability has been demonstrated for this time period.

Exhaustive extractions were started for wheat straw and wheat grain within approx. two to seven months after harvest. Since the compounds identified in the exhaustive extracts were comparable with the compounds of the conventional extracts, it was concluded that the residues in the solids were stable and reflected the released residues at the time of exhaustive extraction.

Thus it can be concluded that the residues in all matrices were sufficiently stable during the experimental period of the study and that the first quantified profiles represented the metabolic pattern in the samples at harvest. Nevertheless, storage stability of BYI 02960 residues in frozen sample material was additionally demonstrated in wheat straw (1st and 2nd rotation) and in Swiss chard (1st rotation) for a storage period of about 18 to 24 months by qualitatively and quantitatively comparing raw chromatography data . The stored sample material was subjected to a second extraction. Analysis of the new extracts showed the same metabolite patterns as the first extracts and confirmed the storage stability of the residues in the stored RACs.

Extract stability has been demonstrated for the time of the sample preparation and the identification process of metabolites, as well: The metabolite patterns of stored extracts remained stable when re-analysing extracts, e.g. for isolation of metabolites or identification purposes. Neither significant degradation nor transformation of metabolites in extracts was observed.

Hence, it was concluded that the results of the present study were not impacted by the storage of the samples and that no further storage stability investigations are required.

Results

The TRR values of all RACs declined significantly (by a factor of 5 to 13) from the first to the third rotation. Highest residues were detected in the non-edible commodities wheat straw and wheat hay, as shown in Table 7.1.2-1.

Table 7.1.2-1 TRR values in the different RACs of the three rotations after soil application of [furanone-4-^{14}C]BYI 02960 (Plant Back intervals of 29, 135 and 296 days)

TRR [mg/kg]	Wheat				Swiss chard		Turnips	
	forage	hay	straw	grain	imm.	mature	leaves	roots
1st rotation	0.78	2.0	6.3	0.48	0.85	0.87	0.68	0.074
2nd rotation	0.19	1.1	1.5	0.10	0.31	0.26	0.16	0.014
3rd rotation	0.11	0.25	0.46	0.047	0.18	0.15	0.090	0.008

Except for wheat grain, extraction efficiencies ranged from 70% to 97% for all commodities of all rotations after conventional extraction. Subsequent exhaustive extraction steps (microwave and/or digestive extraction steps), applied to the post extraction solids in wheat grain and wheat straw, increased the extraction efficiencies to a range of 83% to 98% of the TRR.

Parent compound BYI 02960 and about 30 metabolites were detected in the conventional and exhaustive extracts of the various samples of the three rotations. Of these the active substance and 14 metabolites were identified by LC-MS/MS. The other metabolites, none of them exceeding 5% of the TRR or 0.05 mg/kg, were characterised by their extraction behaviour and their retention in radio-HPLC or TLC. The amounts of active substance and metabolites in all RACs are summarized in Table 7.1.2-2 to Table 7.1.2-9 for the three rotations.

Parent compound was by far the main component detected in all matrices of all rotations, except for wheat grain. Parent accounted for 34% to 64% of the TRR in the commodities of the 1st rotation, for 28% to 68% in the 2nd rotation and covered 18% to 72% in the 3rd rotation, not considering grains. In wheat grains, only trace amounts of parent compound were detected (<1% and 2% of the TRR). The highest proportion of parent compound was always detected in turnip leaves.

Six of the identified metabolites were specific to the radiolabel used: BYI 02960-difluoroethyl-amino-furanone, its conjugate BYI 02960-mercapto-lactic acid, BYI 02960-difluoroethyl-amino-furanone-OH-glyc, BYI 02960-amino-furanone, BYI 02960-bromo-amino-furanone, and the natural compound glucose (or probably an isomeric carbohydrate). The natural compound was identified as the main component in wheat grain after subjecting the post extraction solids of the conventional extraction (1st rotation) to a diastase digestion step. The released radioactivity in the aqueous digestion solution was partitioned against dichloromethane. The majority of the radioactivity remained in the aqueous phase indicating that the metabolite was probably a polar natural compound. Isolation of the polar fraction by semi-preparative HPLC and following analysis by normal phase TLC showed one spot indicating that the fraction is represented most probably by one compound. TLC co-chromatography with the natural

compound isolated and identified in the tomato metabolism study with [furanone-4-^{14}C]BYI 02960 confirmed the correspondance of the metabolites. TLC analysis of the isolated polar fractions detected in the conventional and exhaustive extracts of wheat straw and in the conventional extracts of Swiss chard and turnip roots revealed that these fractions were represented by several compound (up to eight). Only minor percentages of the fractions appear identical with glucose. Based upon TLC, for turnip roots, a trace amount was assigned to the natural compound.

Label unspecific metabolites (= metabolites common to both radiolabels tested) were BYI 02960-OH and its conjugates, BYI 02960-acetic acid, its conjugate BYI 02960-acetic acid-glyc and its successor molecule BYI 02960-glyoxylic acid and the chlorinated/brominated parent compound. These metabolites were also detected in the CRC study conducted with [pyridinylmethyl-^{14}C]BYI 02960. The metabolites BYI 02960-acetic acid and BYI 02960-OH-glyc were not separated by the HPLC profiling method and co-eluted in one peak or one peak zone. Separation and sub-quantification of the metabolites was shown for wheat straw (1st rotation), Swiss chard (1st rotation) and turnip leaves (1st rotation) as representative crops. Therefore the corresponding peak zones were isolated by semi-preparative HPLC, concentrated and re-analysed with an acidic HPLC method which separated the two metabolites. The ratios of BYI 02960-acetic acid and BYI 02960-OH-glyc obtained for wheat straw were assigned to all wheat samples, the ratio of Swiss chard to immature and mature Swiss chard, and the ratio of turnip leaves to turnip roots of all rotations. BYI 02960-OH-glyc was the prominent compound in all samples of all rotations.

Overall, identification rates were high for all samples of all rotations. For some RACs (e.g., wheat straw and wheat grain), high identification rates were only shown for the 1st and 2nd rotation (or in the case of grains for the 1st rotation only) since exhaustive extraction and following analysis of the exhaustive extracts was only conducted exemplarily for these samples. Thus, lower identification rates in this study were generally linked to higher bound residues (wheat matrices) and no subsequent exhaustive extraction step. In the case of turnip roots of the 2nd rotation, the identification rate was also quite low (53%) since one unknown compound represented a high percentage of the TRR, but at a very low residue level (0.004 mg/kg).

* post extraction solids
[1] polar unkown peak 1a in Swiss chard of 1st rotation consisted of 8 different metabolites, all of them were minor according to TLC subquantification

Conclusions

Parent compound was the most prominent compound in all RACs of all rotations, except in wheat grains, where it was detected as a minor compound only. The main compound detected in grains accounted for approx. 70% of the TRR in the sample of the 1st rotation and was identified as a natural compound (glucose/carbohydrates). Major metabolites in other wheat RACs, Swiss chard and turnips were BYI 02960-OH-glyc, -glyoxylic acid, -difluoroethyl-amino-furanone, -difluorethyl-amino-furanone-OH-glyc and BYI 02960-bromo-amino-furanone which were detected in a range of approx. 10% - 22% of the TRR in numerous samples. All other identified metabolites were detected at minor or trace levels. In total, fourteen metabolites were identified; six of them were specific to the radiolabel tested.

[Furanone-4-^{14}C]BYI 02960 was rather extensively metabolised in confined rotational crops. The following metabolic routes were observed:

- cleavage of the pyridinylmethylamine bond and formation of metabolites based on difluoroethyl-amino-furanone and amino-furanone structures,
- BYI 02960-difluorethyl-amino-furanone conjugation with either mercapto-lactic acid or conjugation with carbohydrates after hydroxylation,
- hydroxylation of the methylene group of the furanone moiety followed by conjugation with carbohydrates and sulphate,
- oxidative degradation of the furanone moiety to BYI 02960-acetic acid, which was either subjected to conjugation with glucose or to a further oxidation step
- complete degradation of the furanone moiety and incorporation of carbon atoms into the natural compound pool, i.e. into glucose/carbohydrates, and
- halogenation of the furanone ring with bromine or chlorine.

Halogenation of the furanone moiety of the active substance probably occurred in the soil which is supported by the fact that small amounts of halogenated parent compound have been identified in the aerobic soil degradation studies. Metabolite BYI 02960-glyoxylic acid, the oxidation product of BYI 02960-acetic acid, was probably a transient soil metabolite that was taken up by the plants, since it was only prominent in the samples of the 1st rotation.

On the basis of the results of this study it is concluded that the metabolism of [furanone-4-^{14}C]BYI 02960 in confined rotational crops is well understood and the following metabolic pathway is proposed:

Figure 7.1.2-1 Proposed metabolic pathway of [furanone-4-^{14}C]BYI 02960 in confined rotational crops

Study 2

Characteristics

Reference	:	Breuer-Rehm, M.; 2011 KIIA 6.6.2/02	Application rate	:	433 g a.s./ha (1.75N)
Type of study	:	Metabolism in Rotational Crops	Area	:	planting container with a surface area of 1 m^2
Year of execution	:	2008-2011	Plant	:	wheat (cereal), Swiss chard (leafy vegetable) and turnips (root vegetable)
Test substance	:	[pyridinylmethyl-^{14}C] Flupyradifurone ; sample ID: KATH 6105; ; purity >99% w/w; batch ID 2008-0.02556	Plant back intervals	:	29, 135 and 296 days
GLP statement	:	Yes	Acceptability	:	Acceptable

Description

Test material

Chemical structure	* position of the radiolabel
Radiolabelled test material	[pyridinylmethyl-^{14}C]BYI 02960
Specific radioactivity (before radiodilution)	4.37 MBq/mg (118.08 µCi/mg)
Chemical Purity	> 99% (HPLC)
Radiochemical purity	> 99% (HPLC and TLC)

Experimental conditions

The metabolism of flupyradifurone was investigated in the representative rotational crops wheat (cereal), Swiss chard (leafy vegetable) and turnips (root vegetable) from three consecutive rotations. [Pyridinylmethyl-^{14}C]BYI 02960 was formulated as an SL 300 and used for one spray application onto the soil of a planting container (approx. 1 m^2). The actual application rate corresponded to 433 g a.s./ha, above the anticipated maximum seasonal field rate of 250 g a.s./ha (1.75N) for EU uses and 400 g a.s./ha for US uses. The crops were each sown at 29, 135 and 296 days after the soil application, representing the first, second and third rotation.

Sampling

Intermediate raw agricultural commodities (RACs) investigated were Swiss chard immature (BBCH 44-46), wheat forage (at BBCH growth stage 29-31) and wheat hay (sampled at BBCH 79-83 and dried

for five days). All other RACs (wheat straw, wheat grain, Swiss chard, turnip leaves and turnip roots) were harvested at maturity.

Extraction and quantification

An aliquot of each homogenized RAC was extracted conventionally three to four times with ACN/water (8:2, v/v). The extracts were combined, purified using a pre-conditioned SPE RP 18 cartridge, concentrated and analysed by HPLC. The radioactivity in the extracts was determined by LSC, in the solids by combustion followed by LSC. The actual TRR values of the samples were determined by summing up the radioactivity measured in the extracts and in the remaining solids.

Post-extraction solids of forage and hay (1st rotation) were extracted two times with an ACN/water mixture under microwave assistance at increased temperature.

Post-extraction solids of wheat straw (1st rotation) were subjected to a sequential extraction procedure after one exhaustive extraction step with ACN/water (8:2, v/v) at increased temperature (60 °C) under microwave conditions. The solids of the microwave extraction step were subjected to a treatment with sodium chloride solution (2 h at 100 °C under microwave assistance), a diastase incubation (approx. 6 h at 26°C), a treatment with EDTA solution (1 h at 100 °C under microwave assistance) and a cellulase treatment (approx. 12 h at 40 °C) at adjusted temperatures to break down the plant cell walls and liberate residues bound to cell walls or in the cells. The remaining solids of the sequential extraction were extracted finally in two steps with a 5N HCl and a 0.1N NaOH solution. Extracts of the EDTA, the cellulase and the HCl treatment were combined and adjusted to pH 7. The extract was concentrated, centrifuged and analysed by HPLC. The NaOH extract was not submitted to HPLC due to its high viscosity.

Post-extraction solids of grains (1st rotation) were subjected to four subsequent exhaustive extraction steps under microwave conditions at increased temperature. Extraction was performed with ACN/water mixtures, 0.1N HCL and 0.1N NaOH.The ACN/water extracts were combined, concentrated and analysed by HPLC. The post-extraction solids of grains of the 2nd rotation were subjected to one exhaustive extraction step with ACN/water (8:2, v/v) at increased temperature under microwave assistance, followed by a diastase digestion (20 h at 26 °C) and a treatment with sodium chloride solution at 100 °C. HPLC analysis of the extracts was not performed due to the low radioactivity levels in the extracts.

Identification an characterisation

Identification was achieved by spectroscopic evidence (LC-MS/MS) after isolation and purification of the respective compounds from the conventional extracts of wheat straw or Swiss chard of the 1st rotation. HPLC co-chromatography with the isolated and identified radiolabelled metabolites and HPLC comparison of metabolic profiles of the different extracts allowed the assignment of the

compounds in all other extracts.

Storage stability

All conventional extraction experiments and the first HPLC analyses were performed within 9 days after harvest of the plants, with the exception for wheat grain of the second rotation which was extracted within 7 days after harvest, but analysed only 154 days after harvest. Therefore, the extract stability was investigated by re-analysing the grain extract after a storage time of more than 21 months in the freezer at ≤ -18 °C. No change in the metabolite pattern was detected indicating that the residues in the extracts are stability for at least 21 months.

Quantitative ^{14}C-HPLC analysis of the extracts was performed with the profiling method BYI02960_NEUTR. Only for wheat forage and hay, Swiss chard and turnips from the 1st rotation, the metabolic profile was measured with the preliminary profiling method BYI02960_CRC directly after extraction. The preliminary method was based on the same type of column and the same eluents but had a slightly shorter gradient. The metabolite profiles obtained from the two methods were comparable, however profiling method BYI02960_NEUTR showed an improved separation for some metabolites. For better comparison of metabolic pattern over all RACs of all rotations, the profiles of wheat forage and hay, Swiss chard and turnips of the 1st rotation were re-analysed with method BYI02960_NEUTR about 1 – 2 months after extract preparation. These new metabolic profiles were then considered as basis for quantification. Extract stability has been demonstrated for this time period.

Exhaustive extractions were started within approx. four to seven months after harvest. Since the compounds identified in the exhaustive extracts were identical with the compounds of the conventional extracts, it was concluded that the residues in the solids were stable and reflected the released residues at the time of exhaustive extraction.

Thus it can be concluded that the residues in all matrices were sufficiently stable during the experimental period of the study and that the first quantified profiles represented the metabolic pattern in the samples at harvest. Nevertheless, storage stability of BYI 02960 residues in frozen sample material was additionally demonstrated for Swiss chard and wheat straw for at least 20 or 18 months, respectively. Swiss chard and wheat straw samples were extracted and analysed for a second time after storage of the samples at ≤ -18 °C for at least 18 months. Comparison of the HPLC profiles showed no changes in the metabolite patterns.

As well, extract stability was proven for selected matrices (wheat forage, wheat grain, Swiss chard, turnip leaves and turnip roots) by re-analysis of stored extracts. All extracts were stable for at least 4 months (period tested for turnip roots). For wheat grain an extract stability of at least 21 months was demonstrated, as mentioned above.

Results

The TRR values of all RACs declined significantly (by a factor of 7 to 18) from the first to the third rotation. Highest residues were detected in the non-edible commodities of wheat and in the edible commodities of Swiss chard, as shown in Table 7.1.2-10.

Table 7.1.2-10 TRR values in the different RACs of the three rotations after soil application of [pyridinylmethyl-^{14}C]BYI 02960 (Plant Back intervals of 29, 135 and 296 days)

TRR [mg/kg]	Wheat				Swiss chard		Turnips	
	forage	hay	straw	grain	imm.	mature	leaves	roots
1st rotation	1.4	2.4	9.0	0.18	1.4	1.5	0.82	0.072
2nd rotation	0.301	1.0	2.1	0.057	0.33	0.44	0.23	0.022
3rd rotation	0.12	0.32	0.49	0.017	0.14	0.13	0.083	0.008

The radioactive residues were efficiently extracted from all commodities of all rotations with acetonitrile/water mixtures, except for wheat grain where only 35.4% to 52.2% of the TRR was detected after conventional extraction. For all wheat matrices additional exhaustive extraction steps were applied to the solids after conventional extraction. Exhaustive extraction comprised one to two extraction steps with acetonitrile/water mixtures at increased temperature (60 °C) under microwave assistance and in the case of wheat straw (1st and 2nd rotation) and wheat grain (2nd rotation) additional sequential extraction steps including enzymatic digestion steps. For wheat grain, exhaustive extraction released additional high amounts of radioactivity from the post-extraction solids. The extracted portions increased from 52.2% to 83.8% of the TRR (1st rotation) and from 35.4% to 89.4% of the TRR (2nd rotation). For the other wheat matrices, the additionally extracted portions ranged between 3.5% and 20.5% of the TRR depending on the exhaustive extraction steps applied. Thus, extraction efficiencies were increased significantly by exhaustive extraction steps, if applied – and extraction efficiencies above 80% resulted, even for wheat grain.

Parent compound BYI 02960 and about 50 metabolites were detected in the conventional and exhaustive extracts of the various samples of the three rotations. Of these the active substance and 17 metabolites were identified by LC-MS/MS. The other metabolites, none exceeding 5% of the TRR or 0.05 mg/kg, were characterised by their extraction behaviour and their retention time in radio-HPLC. The amounts of active substance and metabolites in all RACs are summarized in Table 7.1.2-11 to Table 7.1.2-18 for the three rotations.

Except in wheat grain, parent compound was by far the main component detected in all matrices of all rotations, accounting for 8% to 62% of the TRR in the commodities of the 1st rotation, 1% to 67% in the 2nd rotation and 14% to 69% in the 3rd rotation. The lowest percentage was always detected in wheat grain and the highest in turnip leaves.

Eight of the identified metabolites were specific to the radiolabel used: BYI 02960-CHMP, three

different conjugates of this metabolite, the corresponding oxidation product 6-CNA and its glycerol-glucuronic acid conjugates (3 isomers) and two oxidation products of the postulated cleavage product BYI 02960-AMCP-difluoroethanamine. The isomers of 6-CNA-glycerol-gluA were detected as major metabolites in all matrices of wheat. In wheat grains they represented the highest proportion of the TRR. It is probable that the weak acid 6-CNA with its pronounced phloem mobility was transported into the seeds as a phloem sink, with conjugation occurring after transport. The 6-CNA conjugates were not identified in the matrices of Swiss chard or turnips.

Identified metabolites common to both radiolabels were BYI 02960-OH and its conjugates, BYI 02960-acetic acid, its conjugates and its successor molecule BYI 02960-glyoxylic acid and the chlorinated/brominated parent compound.

Overall, identification rates were high and ranged from 68% - 87% of the TRR in all RACs apart from wheat grains. In grains the identification rate was lower (29% - 58% of the TRR), but at least additional significant portions of the TRR were characterized by the extraction behaviour of the residues. The solids remaining after the conventional extraction of the grains of the 2nd rotation were subjected in a first step to microwave extraction with ACN/water (8:2, v/v) at increased temperature (15 min at 100 °C). An additional portion of approx. 5% of the TRR was released. Analysis of this extract showed the known major compounds of the conventional extract besides a high amount of a polar unknown compound. Enzymatic treatment of the post-extraction solids of the microwave extraction with diastase (approx. 20 h at 26 °C) solubilised a significant higher portion of the TRR (approx. 21% of the TRR), indicating that a quite polar residue was released. Subsequent extraction of the remaining solids with a sodium chloride solution (2 h at 100 °C) released another significant portion of the TRR (approx. 28% of the TRR). These extraction steps indicate that a major part of the residues in grain is of polar nature – and can be most probably assigned to natural compounds.

Conclusions

[Pyridinylmethyl-^{14}C]BYI 02960 was rather extensively metabolised in confined rotational crops. However, parent compound was detected as main component in all RACs of all rotations, except in wheat grain of the first and the second rotation. Considering all samples, BYI 02960-6-CNA-glycerol-gluA (a mixture of two isomers) was the main metabolite in the wheat matrices and BYI 02960-OH-glyc was the main metabolite detected in Swiss chard and turnips. The following main metabolic routes were observed:

- cleavage of the pyridinylmethylamine bond followed by conjugation with carbohydrates and sulphate or by oxidation of the methylene group to a carboxylic group,
- hydroxylation of the methylene group of the furanone moiety followed by conjugation with carbohydrates and sulphate,
- cleavage or complete degradation of the furanone moiety followed by several oxidation and conjugation reactions, and
- halogenation of the furanone moiety with bromine or chlorine.

Halogenation of the furanone moiety of the active substance probably occurred in the soil which is supported by the fact that small amounts of halogenated parent compound were identified in the aerobic soil degradation studies.

On the basis of the results of this study it is concluded that the metabolism of [pyridinylmethyl-^{14}C]BYI 02960 in confined rotational crops is well understood and the following metabolic pathway is proposed:

Guidelines & Limitations

The level of extraction, identification and characterisation in plant samples is sufficient. The study results are reliable and acceptable.

Figure 7.1.2-2 Proposed metabolic pathway of [pyridinylmethyl-^{14}C]BYI 02960 in confined rotational crops

Overall conclusion for confined rotational crops

The metabolism of the insecticide BYI 02960 was investigated in the rotational crops wheat, Swiss chard and turnips from three consecutive rotations in two separate experiments with (1) [furanone-4-^{14}C]BYI 02960 or (2) [pyridinylmethyl-^{14}C]BYI 02960. In each study, parent compound was applied to the bare soil 29 days before sowing of the crops of the first rotation. The plant back intervals were 29, 135 and 296 days after the soil application, representing the first, second and third rotation. Sample materials under investigation were the immature raw agricultural commodities wheat forage, wheat hay and Swiss chard at an intermediate growth stage and the mature raw agricultural commodities wheat straw and wheat grain, Swiss chard and turnip leaves and roots.

(1) Label 1: [furanone-4-^{14}C]BYI 02960

The total radioactive residues (TRR) in all RACs declined significantly from the first to the third rotation. Parent compound was the main component detected in all RACs in all rotations (except for wheat grain), indicating that no major metabolites were formed in the soil and taken up by the plants. These results are in line with the aerobic soil degradation studies which show a quite high mineralization rate of BYI 02960, with only two major soil metabolites detected, both of them being label-specific and not possible to detect in the present study. The formation of BYI 02960-chloro and BYI 02960-bromo in soil was detected to a minor extent. Subsequent uptake of these soil metabolites is most probably the explanation for the trace levels detected in the different RACs. Further degradation of these halogenated compounds in the plant was probably the cause of metabolites such as BYI 02960-bromo-amino-furanone.

The main metabolite in wheat grains was assigned to a natural compound. Diastase digestion of the post extraction solids of the conventional extraction led to one polar metabolite which was identified as glucose by TLC co-chromatography. Radiolabelled glucose was also found in trace levels in turnip roots. Other label-specific metabolites identified were BYI 02960-difluoroethyl-amino-furanone, its conjugates BYI 02960-mercapto-lactic acid and BYI 02960-difluoroethyl-amino-furanone-OH-glyc, as well as the metabolites BYI 02960-amino-furanone and BYI 02960-bromo-amino-furanone. All other identified metabolites were not label specific and were detected at comparable residue levels in the CRC study performed with [pyridinylmethyl-^{14}C]BYI 02960.

On basis of the metabolites identified, the metabolic pathway was deduced. One major metabolic route was the cleavage of the pyridinylmethylamine bond and the formation of BYI 02960-difluoroethylamino-furanone and BYI 02960-amino-furanone after loss of the difluoroethyl moiety. The cleavage of the molecule was also detected in the CRC study conducted with [pyridinylmethyl-^{14}C]BYI 02960. BYI 02960-CHMP, 6-CNA and conjugates of these metabolites were identified as the corresponding counterparts. Oxidative degradation of the furanone moiety was also an important degradation path resulting in the metabolites BYI 02960-acetic acid, BYI 02960-glyoxylic and

corresponding conjugates. Hydroxylation of the furanone moiety and subsequent conjugation with carbohydrates was an additional metabolic route resulting in metabolites common to both radiolabels tested. Complete degradation of the furanone moiety and incorporation of the carbon atoms into the natural compound pool, i.e. most probably into glucose was also observed. Halogenation of the furanone moiety of the active substance was most probably a process which occurred in the soil.

The results of the present metabolism study in confined rotation crops are in good conformity with the results of the corresponding study performed with [pyridinylmethyl-^{14}C]BYI 02960.

(2) Label 2: [pyridinylmethyl-^{14}C]BYI 02960

The total radioactive residues (TRR) in all RACs declined significantly from the first to the third rotation. Parent compound was the main component detected in most of the RACs in all rotation (not in wheat grain of the 1st rotation, not in wheat grain and mature Swiss chard in the 2nd rotation, and not in wheat hay, wheat straw and mature Swiss chard of the 3rd rotation). Other major metabolites were the glucuronic acid conjugates of 6-CNA-glycerol (which were detected in quite high amounts in all wheat matrices) and BYI 02960-OH-glyc (which were detected in significant amounts in Swiss chard). These results are in line with the aerobic soil degradation studies which show a quite high mineralization rate of BYI 02960, with only two major soil metabolites detected, one of them being label-specific and not possible to detect in the present study, and the other 6-CNA, which would be expected to be taken up by the plants and further metabolized (conjugated). The formation of 6-CNA is expected to also occur in the plant, supported by the fact that the preceding metabolite BYI 02960-CHMP - or conjugates of it - were also identified in several plant matrices. Metabolite 6-CNA and its preciding metabolite BYI 02960-CHMP, as well as their corresponding conjugates were the only label specific metabolites detected. All other metabolites identified were not label specific and were detected at comparable residue levels in the CRC study performed with [furanone-4-^{14}C]BYI 02960.

On basis of the metabolites identified, the metabolic pathway was deduced. Overall, three major metabolic routes were detected: (1) Cleavage of the pyridinylmethylamine bond followed by conjugation with carbohydrates and sulphate or by oxidation of the methylene group to a carboxylic group and further conjugation, (2) hydroxylation of the methylene group of the furanone moiety followed by conjugation with carbohydrates and sulphate, and (3) cleavage or complete degradation of the furanone moiety followed by several oxidation and conjugation reactions. Halogenation of the furanone moiety of the active substance was most probably a process which occurred in the soil. Most probably the metabolites were taken up by the roots and were not formed in the plants. This is in line with the finding of the aerobic soil degradation studies summarized in KAII 7.1.

The cleavage of the molecule was also detected in the CRC study conducted with [furanone-4-^{14}C]BYI 02960. BYI 02960-difluoroethyl-amino-furanone and BYI 02960-amino-furanone and conjugates of these metabolites were identified as the corresponding counterparts to BYI 02960-

CHMP and 6-CNA or their conjugates. Thus, the results of the present metabolism study in confined rotation crops are in good conformity with the results of the corresponding study performed with [furanone-4-^{14}C]BYI 02960.

When considering the results from both confined rotational crop studies conducted, it can be concluded that BYI02960 is rather extensively metabolised in rotational crops. A total of 6 major and approx. 40 minor metabolites were found, and all major and 14 minor have been identified. The distribution of parent compound and metabolites in the edible matrices of confined rotational crops are shown in Table 7.1.2-19 to Table 7.1.2-25.

In order to gain information on the fate of the difluoroethane moiety of BYI 02960, the extracts obtained in the CRC study with [furanone-4-^{14}C]BYI 02960 were additionally analysed for non-radiolabelled difluoroacetic acid by LC-MS/MS according to residue method 01304. Significant levels of difluoroacetic acid were detected in all plant matrices of the first and second rotation. DFA represented the main proportion of the residues in the edible crops wheat grain, Swiss chard and turnip roots and as well as in the feed item wheat hay. In wheat forage and straw and turnip leaves, DFA was less prominent than parent, but it was still a major compound.

In corresponding crop samples from different plant back intervals, the DFA levels generally decreased significantly from the first to the third rotation, showing DFA levels slightly above or below the limit of quantification in all crops of the third rotation. The highest DFA concentrations were detected in wheat grains ranging from 4.45 mg a.s. equiv./kg in the first rotation to 0.15 mg a.s. equiv./kg in the third rotation.

On basis of the metabolites identified, biotransformation of BYI 02960 in confined rotational crops proceeds by the following main pathways:

- oxidative cleavage of the difluoroethylamine bond and formation of difluoroacetic acid
- cleavage of the pyridinylmethylamine bond and formation of BYI 02960-difluoroethyl-amino-furanone and the corresponding counterparts BYI 02960-CHMP and 6-CNA followed by several conjugation reactions
- cleavage of the furanone moiety followed by several oxidation and conjugation reactions
- complete degradation of the furanone moiety and incorporation of carbon atoms into the natural compound pool, e.g. into glucose/carbohydrates
- hydroxylation of the methylene group of the furanone moiety followed by conjugation with carbohydrates and sulphate
- halogenation (bromination and most probably chlorination, as well) of the furanone moiety

Halogenation of the furanone moiety of the active substance probably occurred in the soil which is supported by the fact that small amounts of halogenated parent compound were identified in the aerobic soil degradation studies.

The positions involved in the metabolic degradation are summarised in the following figure.

B.7.2 Metabolism, distribution and expression of residues in livestock (IIA 6.2.2, IIA 6.2.3, IIA 6.2.4 and IIIA 8.2)

Both crops, i.e. lettuce and hops, in the intended use for the European evaluation of flupyradifurone are not used as livestock feed. Nevertheless, the applicant submitted livestock metabolism and livestock feeding studies, anticipating future uses on feeding crops in EU and with regard to residues that can occur in crops grown in rotation (see B.7.9). ~~Furthermore, use on several crops that can be used as livestock feed is authorised in Australia, Brazil, Canada, Mexico and US (Partners in the Joint Global Review), i.e. potatoes and other root and tuber vegeatbles, kale, beans, pome fruits, cereal grains and corn, clover seed forage, soy bean and cotton seed. An MRL dossier was already received by the RMS and has been evaluated. However, it is assumed that imported crops are generally not used as livestock feed.~~

Livestock diet calculations were conducted using the results from the rotational crops and EU uses on feeding crops supported in the MRL dossier.

For the dietary burden calculator, the ~~separate~~ total residues of flupyradifurone and DFA were used as input, since residue levels of flupyradifurone are at or below LOQ in rotational crops and DFA is the major contributor to the total residue level (levels of DFEAF at or below LOQ). The metabolism and feeding studies were carried out with flupyradifurone only. The residues are separated into BYI 02960 and DFA residues in the worst-case diet to estimate the expected worst-case residue levels in products of anilmal origin of the two compounds in animal matrices on the basis of the different transfer factors determined in the feeding studies (See B.7.8 and B.7.12).

The input values for the dietary burden calculator are:

~~* Based on STMR (0.02 mg/kg) and HR (0.069 mg/kg) from the supervised residue trials (dataset NEU and SEU together) and a mean P-factor of 0.75 for DFA.~~

The results in Table 7.2-3 show that the theoretical intake of ~~total~~ flupyradifurone ~~(~~parent and DFA~~)~~, separately, residues from rotational crops and pome fruit is more than 0.1 mg/kg diet (DM) for cattle, poultry and pigs. Therefore, metabolism studies in these species are required. The N rate in the studies was not calculated ~~for the total flupyradifurone residues~~, since ~~whilst~~ the animals were dosed with parent only. ~~Hence, the N rate is provisional.~~

Calculation of dietary burden

The estimated dietary burden of ~~total~~ BYI 02960 and DFA residues in livestock commodities, based on EU crop residue data and the European dietary burden calculator, are presented for poultry, cattle and pigs below in table 7.2-3.

B.7.2.1 Summary of studies in ruminants and poultry

Poultry

STUDY 1

Characteristics

Reference	:	[redacted] 2012a KIIA 6.2.2/01	GLP statement	:	Yes
Type of study	:	Metabolism in laying hen	Guideline	:	OECD-Guideline for the Testing of Chemicals No. 503: Metabolism in Livestock US-EPA, Residue Chemistry OPPTS 860.1300;
Year of execution	:	2010-2011	Dose	:	14 consecutive days with a 1.02 mg/kg body weight
Test substance	:	(1) [Pyridinyl,ethyl-^{14}C]BYI02960, radiochemical purity > 99 % by radio-HPLC and > 98 % by radio-TLC (2) Nonlabeled testsubstance Batch BYI 02960-PU-02, chemical purity 99,4%	Vehicle	:	0.5 % aqueous Tragacanth® suspension
			Concentration in feed	:	16.18 mg a.s. /kg dry feed/day 1.02 mg/kg bw/d
			Sampling	:	Eggs, excreta, liver, gall bladder, kidneys, leg and breast muscle, skin without subcutaneous fat, subcutaneous fat and eggs from the ovary and oviduct
Animal	:	Laying hen (*Gallus gallus domesticus*) White Leghorn	Acceptability	:	acceptable

Study design

The metabolism and excretion of [pyridinylmethyl-^{14}C]BYI 02960 (common name: flupyradifurone) were investigated in laying hens (White Leghorn). Six hens (mean body weight 1.64 kg) were orally dosed once daily in the morning for 14 consecutive days with an aqueous 0.5% Tragacanth® suspension of 1.02 mg/kg body weight (3.50 MBq/mg after radiodilution) which corresponded to 16.18 mg a.s./kg dry feed/day ~~(12N–11N)~~. The animals were sacrificed six hours after the last administration. Total radioactive residues (TRR) were determined daily in the eggs and excreta, and at sacrifice in the dissected organs and tissues (muscle, fat, liver, kidney, skin and eggs from ovary/oviduct). Eggs, muscle, fat, liver and excreta were extracted and analysed for parent compound and metabolites.

Results

For analysis of parent compound and metabolites, eggs, muscle, fat, liver and excreta from day 13 were pooled from all six animals. Eggs, muscle and liver as well as excreta were conventionally extracted with mixtures of acetonitrile/water and pure acetonitrile. Fat was extracted with acetonitrile and n-heptane followed by a partition procedure yielding an acetonitrile and n-heptane phase. Post-extraction solids of liver were exhaustively extracted using microwave assistance. The resulting extracts of eggs, muscle and liver represented over 92% of the total radioactive residue (TRR). Approx. 80% of the TRR was extractable in fat. Residues in solids of fat were very low and amounted to 0.004 mg/kg, only.

After purification and concentration, the extracts were analysed using HPLC with radiometric detection. The HPLC profiling method was based on the use of a reversed phase column and a neutral water/acetonitrile gradient.

The metabolite pattern of the extracts of the current hen study and the hen study with the ^{14}C-label in the furanone ring of the molecule were comparable, except the label specific metabolites (see study 2 below).

The metabolic profile of excreta was similar to profiles from eggs, organs and tissues.

Therefore parent compound and metabolites were isolated from excreta and identified by LC-MS/MS or NMR. The identied metabolites were used as reference compounds for the assignment in extracts of eggs, muscle, fat and liver by HPLC cochromatography.

The overall recovery rate was 96.11% of the total dose. The remaining radioactivity was expected to still be present in the gastro-intestinal tract at sacrifice, due to the short period between the last administration and sacrifice. On average, only 0.24% of the total dose was measured in the eggs. At sacrifice, the radioactive residues in the organs and tissues were calculated or estimated to be about 0.37% of the total dose, half of which was detected in the skeletal muscle (0.19%). Until sacrifice, the excretion of radioactivity accounted for 95.51% of the total dose.

The concentration of radioactivity in eggs ranged from 0.016 mg/kg at day one to 0.119 mg/kg at sacrifice. Following a rather linear increase, a plateau level of approx. 0.08 mg/kg was reached six days after the first administration.

In the organs and tissues, the highest radioactivity concentrations were determined in kidney (1.073 mg/kg) and liver (0.435 mg/kg) indicating the significance of these organs for excretion and metabolism. These values corresponded to 0.05% and 0.08% of the total dose, respectively. The residue level of the eggs collected from the ovary and oviduct at sacrifice (0.147 mg/kg) was insignificantly higher than the levels of the laid eggs collected at sacrifice (0.119 mg/kg). This indicated that the egg yolk was not a preferential site for secretion. The residue levels of liver and kidney were followed in decreasing order by those found in the skin (0.094 mg/kg), muscle (0.070 mg/kg) and subcutaneous fat (0.021 mg/kg). The residue level of the total muscle corresponded to about 0.19% of the total dose assuming a value of 40% of the body weight for this tissue. Assuming values of 12% and 4% of the body weight for fat and skin, the residues in both tissues accounted for about 0.04% of the total dose.

Approx. 86% of TRR for eggs, 84% of TRR for muscle, 78% of TRR for fat and 59 % of TRR for liver were identified. All other residues were characterised by extraction and chromatographic behaviour. Generally, the amounts of parent compound and metabolites were very low.

The parent compound was the major compound in eggs, muscle and fat (approx. 10 to 20% of TRR) and amounted on a low level of ≤0.017 mg/kg, only. Major metabolites were BYI 02960-acetyl-AMCP in eggs, muscle and fat and BYI 02960-OH-SA in fat and liver. Other prominent metabolites were BYI 02960-lactato-mercaptyl-nicotinic acid, BYI 02960-6-CNA, BYI 02960-des-difluoroethyl and BYI 02960-OH. Minor residues were identified as BYI 02960-acetyl-cysteinyl-nicotinic acid, BYI 02960-des-difluoroethyl-OHSA and BYI 02960-AMCP-difluoroethanamine-SA. In addition, BYI 02960-acetic acid was detected in excreta. The results are shown in the Tables below.

Table 7.2.1-01 Distribution of residues in eggs, muscle, fat, liver and kidney of laying hens following oral administration of 14 daily doses of [pyridinylmethyl-^{14}C] BYI02960 at a dose rate of 1.02 mg/kg (mean of six hens)

The main metabolic reactions of [pyridinylmethyl-14C-]BYI 02960 in the laying hen were:

- hydroxylation in position 5 of the furanone ring forming BYI 02960-hydroxy followed by conjugation with sulfuric acid to BYI 02960-OH-SA
- oxidative cleavage of the pyridinylmethyl moiety forming BYI 02960-6-CNA
- substitution of the chloro group of BYI 02960-6-CNA with glutathione followed by degradation resulting into two conjugates BYI 02960-acetyl-cysteinyl-nicotinic acid and BYI 02960-lactato-mercaptyl-nicotinic acid
- cleavage of the difluoroethyl group forming BYI 02960-des-difluoroethyl followed by hydroxylation and conjugation with sulfuric acid to BYI 02960-des-difluoroethyl- OH-SA
- cleavage of the furanone ring and conjugation with sulfonic acid forming BYI 02960-AMCP-difluoroethanamine-SA
- oxidative degradation of the furanone ring forming BYI 02960-acetic acid
- cleavage of the pyridinylmethyl moiety forming an alcohol conjugated with serine (BYI 02960-CHMP-serinate)
- cleavage of the furanone ring and the difluoroethyl group forming an amine followed by acetylation (BYI 02960-acetyl-AMCP)

Conclusions

Metabolites in Eggs

Besides the parent compound (0.017 mg/kg; 19.8%), major metabolites in eggs were BYI 02960-acetyl-AMCP (0.019 mg/kg; 23.1%) and BYI 02960-OH (0.015 mg/kg, 18.0%). Further metabolites were BYI 02960-lactato-mercaptyl-nicotinic acid, BYI 02960-6-CNA, BYI 02960-des-difluoroethyl, BYI 02960-OH-SA and two unknown metabolites. They were detected in low amounts ≤0.007 mg/kg (≤ 8.5%TRR).

Metabolites in Muscle

The main metabolite in muscle was BYI 02960-acetyl-AMCP, which amounted to 0.028 mg/kg (40.2%). Parent compound, BYI 02960-6-CNA, BYI 02960-des-difluoroethyl and BYI 02960-OH were quantified in amounts between 0.006 to 0.007 mg/kg (approx. 9%). Minor identified metabolites were BYI 02960-lactato-mercaptyl-nicotinic acid, BYI 02960-des-difluoroethyl-OH-SA and BYI 02960-OH-SA (each ≤0.002 mg/kg). Two unknown metabolites were identified, which were detected in low amounts ≤0.007 mg/kg (≤ 8.5%TRR).

Metabolites in Fat

No residues were detected in the n-heptane phase. The main metabolites in the polar phase of fat were parent compound (0.003 mg/kg, 15.3%), BYI 02960-acetyl-AMCP (0.006 mg/kg, 28.5%) and BYI02960-OH-SA (0.003 mg/kg, 16.2%). All other metabolites were detected in amounts ≤0.001 mg/kg, including one unknown identified metabolite.

Metabolites in Liver

The majority of the radioactive residue (approx. 75%) was extracted with acetonitrile/water. The main metabolites in this extract were BYI 02960-OH-SA (0.098 mg/kg, 22.5%), BYI 02960-lactato-mercaptyl-nicotinic acid (0.068 mg/kg, 15.5%), BYI 02960-6-CNA (0.028 mg/kg, 6.4%) and BYI 02960-acetyl-AMCP (0.027 mg/kg, 6.3%). The parent compound was only detected in negligible amounts of 0.004 mg/kg. All other metabolites amounted to ≤0.014 mg/kg, except one unknown metabolite (0.027 mg/kg, 6.3%). A total of ten unknown metabolites were identified.

Guidelines & Limitations

The study results are reliable and acceptable.

STUDY 2

Study design

The metabolism and excretion of [furanone-4-^{14}C]BYI 02960 (common name: flupyradifurone) were investigated in laying hens (White leghorn). Six hens (mean bodyweight 1.56 kg) were orally dosed once daily in the morning for 14 consecutive days with an aqueous 0.5% Tragacanth® suspension of 1.05 mg of the active substance per kg body weight (3.50 MBq/mg after radiodilution) which corresponded to 17.13 mg a.s./kg dry feed/day ~~(13N–11N)~~. The animals were sacrificed six hours after the last administration. Total radioactive residues were determined daily in the eggs and excreta, and at sacrifice in the dissected organs and tissues (muscle, fat, liver, kidney, skin and eggs from ovary/oviduct). Eggs, muscle, fat, liver and excreta were extracted and analysed for parent compound and metabolites.

Results

For metabolism investigations, eggs of day 2 to 7 and 8 to 13.25, muscle, fat, liver and excreta from day 13 were pooled from all six animals. Eggs, muscle, fat and liver were conventionally extracted with acetonitrile and n-heptane followed by a partition procedure. In case of eggs, muscle and liver the extraction procedure was continued with a mixture of acetonitrile/water. Excreta were conventionally extracted with acetonitrile/water followed by pure acetonitrile.

Post-extraction solids of eggs, muscle and liver were exhaustively extracted with mixtures of acetonitrile/water followed by acetonitrile/water/formic acid using microwave assistance. The extraction efficiencies amounted to greater than 81% of TRR in all samples. Residues in the remaining solids were low and amounted between 0.006 (eggs day 2 to 7) and 0.036 mg/kg (liver).

The overall recovery rate was 82.16% of the total dose. A part of the remaining radioactivity was expected to still be present in the gastro-intestinal tract at sacrifice, due to the short period between

the last administration and sacrifice. Another part is probably exhaled as $^{14}CO^{2}$. The formation of carbon dioxide was also shown in a rat quantitative whole-body autoradiography study using the test compound with the same labelling position (B.6.1, study 4). An average amount of 2.35% of the total dose was determined in the eggs. At sacrifice, the residues in the organs and tissues were calculated or estimated to be about 1.8% of the total dose from which about 28% was detected in the skeletal muscle (0.5%). Until sacrifice, the excretion products accounted for 78.01% of the total dose.
The concentration of radioactivity in eggs ranged from 0.024 mg/kg at day one to 1.198 mg/kg at sacrifice. Following a linear increase a plateau level of 1.035 mg/kg was reached nine days after the first administration.

In the organs and tissues, the highest radioactivity concentrations were determined in liver (2.178 mg/kg) and kidney (1.083 mg/kg) indicating the significance of these organs for metabolism and excretion. These values corresponded to 0.37% and 0.05% of the total dose, respectively. The residue level of the eggs collected from the ovary and oviduct at sacrifice (2.774 mg/kg) was by a factor of 2.3 higher than the levels of the laid eggs collected at sacrifice (1.198 mg/kg). This indicated that the egg yolk was a preferential site for secretion of the radioactivity. The residue levels of liver and kidney were followed in decreasing order by those found in the subcutaneous fat (0.427 mg/kg), skin (0.257 mg/kg) and muscle (0.183 mg/kg). The residue level of the total muscle corresponded to about 0.50% of the total dose assuming a value of 40% of the body weight for this tissue. Assuming values of 12% and 4% of the body weight for fat and skin, the residues in both tissues accounted for about 0.41% of the total dose.
The major part of residues was detected in the n-heptane phases of eggs (days 2 to 7: approx. 52% of TRR and days 8 to 13.25: approx. 58% of TRR), fat (approx. 96% of TRR) and liver (approx. 52% of TRR). The residues in the n-heptane phase of muscle amounted to approx. 8% of TRR, only.
Residues in the conventional acetonitrile/water extract of eggs, muscle, fat and liver were detected in approx. the same residue level as analysed in the laying hen study with the pyridinylmethyl label. The residues amounted between approx. 0.011 mg/kg (2.6% of TRR) for fat and 0.450 mg/kg (20.7% of TRR) for liver.
A significant part of residues was exhaustively extracted using microwave assistance. Between approx. 4 and 10% of TRR were detected in the neutral exhaustive extracts and between 8 and 40% of TRR in the acidic exhaustive extracts of eggs, muscle and liver.
Losses of radioactivity during the extraction procedure of eggs, muscle and liver amounted between 5 and 18% of TRR. No significant radioactivity was detected in distillates. The radioactive residues in the n-heptane phases of eggs, muscle, fat and liver showed the same chromatographic behaviour (TLC) and were identified as fatty acids after saponification. These residues in the n-heptane phases were specific for the furanone label and were caused by the cleavage and subsequent total degradation of the furanone ring to smaller carbon units (C1- or C2-fragments), which entered into the carbon pool of endogenous compounds.

Residues, which were dissolved in the conventional acetonitrile/water extracts and exhaustive extracts were analysed by HPLC with radiometric detection. The metabolite patterns of the current hen study and the corresponding extracts of the hen study with the ^{14}C-label in the pyridinylmethyl ring(see above) were comparable, except the label specific metabolites.

Parent compound, BYI 02960-OH, BYI 02960-OH-SA, BYI 02960-des-difluoroethyl, BYI 02960-des-difluoroethyl-OH-SA were identified in the conventional acetonitrile/water extracts by comparing the retention times and the metabolite pattern from the current study with those from the laying hen study with the pyridinylmethyl label. The metabolites were quantified in nearly the same low amounts as detected in the conventional extracts of the study with the pyridinylmethyl label. In addition BYI 02960-acetic acid was detected in excreta.

The TRRs (expressed as mg a.s. equiv. /kg) and percent of TRR-values, distribution of the parent compound and metabolites and the identification rates in all edible samples are summarised in the table 7.2.2-01

Table 7.2.2-01 Distribution of residues in eggs, muscle, fat, liver and kidney of laying hens following oral administration of 14 daily doses of [furanone-4-^{14}C] BYI02960 pyridinylmethyl-^{14}C] BYI02960 at a dose rate of 1.05 mg/kg

** Both acidic ACN/water extracts of muscle were combined before concentration.

The main metabolic reactions of [furanone-4-^{14}C-]BYI 02960 in the laying hen were:

- cleavage and subsequent total degradation of the furanone ring forming smaller carbon units (C1- or C2-fragments), which entered into the carbon pool of endogenous compounds and were used for example for the biosynthesis of fatty acids
- hydroxylation in position 5 of the furanone ring forming BYI 02960-hydroxy followed by conjugation with sulphuric acid to BYI 02960-OH-SA
- cleavage of the difluoroethyl group forming BYI 02960-des-difluoroethyl followed by hydroxylation and conjugation with sulfuric acid to BYI 02960-des-difluoroethyl-OH-SA
- oxidative degradation of the furanone ring forming BYI 02960-acetic acid

Conclusions

Metabolites in Eggs

The main part of the radioactivity in eggs (days 2 to 7 0.281 mg/kg, 52.0%; days 8 to sacrifice 0.611 mg/kg, 58.3%) was detected in the n-heptane phase and identified as natural fats. The parent compound, BYI 02960-OH, BYI 02960-OH-SA, BYI 02960-des-difluoroethyl and BYI 02960-des-difluoroethyl-OH-SA were identified in low amounts (≤ 0.016 mg/kg, ≤1.6%). Polar metabolites were not further quantified due to the low concentration (≤ 0.010 mg/kg).

Metabolites in Muscle

Residues in the n-heptane phase of muscle were identified as natural fats and amounted to 0.015 mg/kg (8.1%), only. Very low amounts (≤ 0.005 mg/kg) of parent compound, BYI 02960-OH, BYI 02960-des-difluoroethyl and BYI 02960-des-difluoroethyl-OH-SA were identified in the acetonitrile/water extract. Metabolites in the polar region R1 of the acetonitrile/water extract were further analysed and subquantified by thin layer chromatography. The concentrations ranged from 0.001 to 0.012 mg/kg (0.4-6.6%). The commonality of these metabolites with polar metabolites, which were detected in the urine of rats and in the urine, liver and kidney of the goat, was demonstrated by comparison of the thin layer chromatograms.

Metabolites in the acidic exhaustive extract represented the major portion of residues in the muscle sample (0.072 mg/kg, 39.5%). They were characterised by their extraction behaviour. An HPLC analysis could not be performed, due to the high matrix burden in the extract.

Metabolites in Fat

The dominating part of the radioactive residues in fat (0.410 mg/kg. 95.9%) was identified as fatty acids after saponification. The fatty acids were formed from smaller carbon units (C-1- or C-2-fragments), which entered the carbon pool of endogenous compounds after cleavage and subsequent degradation of the furanone ring. A small part (0.011 mg/kg, 2.6%) was detected in the acetonitrile phase and was not further investigated.

Metabolites in Liver

More than half of the residues in liver (1.121 mg/kg, 51.5%) was identified as natural fats. Parent compound, BYI 02960-OH, BYI 02960-OH-SA, BYI 02960-des-difluoroethyl and BYI 02960-des-difluoroethyl-OH-SA were identified in the acetonitrile/water extract. The most prominent metabolite was BYI 02960-OH-SA which amounted to 0.112 mg/kg (5.1%). All other identified metabolites were detected in low amounts between 0.004 and 0.050 mg/kg (0.2-2.3%).

Guidelines & Limitations

The study results are reliable and acceptable.

Animal	:	Lactating goat (*Capra hircus*) 'Weiße Deutsche Edelzeige'	Acceptability	:	acceptable

Study design

The metabolism and excretion of [pyridinylmethyl-^{14}C]BYI 02960 were investigated in the lactating goat. The goat (66 kg body weight) was orally dosed once daily for five consecutive days in the morning after milking with 1.0 mg of the active substance per kg body weight (3.425 MBq/mg after radio dilution) which corresponded to 24.4 mg a.s. /kg dry feed/day ~~(9N)~~. The animal was sacrificed about six hours after the last administration. Total radioactive residues (TRR) were determined in milk and excreta at various sampling intervals, and in muscle, fat, kidney and liver at sacrifice. Milk, edible organs and tissues as well as urine were analysed for the unchanged parent compound and metabolites.

Results

The overall recovery amounted to 88.75% of the total dose. Much of the remaining radioactivity (ca. 11%) was expected to be still present in the gastro-intestinal tract at sacrifice, due to the short period between the last administration and sacrifice. An amount of 0.78% of the total dose was secreted with

the milk. At sacrifice, the residues in the organs and tissues were calculated or estimated to be 2.94% of the total dose from which about 71% was detected in the skeletal muscle.

Until sacrifice, the excretion of radioactivity accounted for 85.02% of the total dose. A portion of 71.74% was found in the urine and 13.28% in the faeces. The urinary and faecal excretion started immediately after the first administration.
The concentration of radioactivity in milk samples ranged from 0.053 mg/kg at 96 hours to 1.345 mg/kg at sacrifice, 102 hours after the first administration. The time course in the evening and morning milk pool samples showed a pronounced diurnal pattern. The radioactive residues increased significantly during the eight hour period after each administration followed by a decrease to a very low level of about 0.05 mg/kg measured prior to the next dosing. A stable plateau level of about 0.3 mg/kg was reached already at 8 hours after the first administration.

In the organs and tissues, the highest concentrations were determined in kidney (1.869 mg/kg) and liver (1.215 mg/kg) indicating the significance of these organs for excretion and metabolism. These values corresponded to 0.10% and 0.50% of the total dose, respectively. For muscle and fat 0.356 mg/kg and 0.106 mg/kg, respectively, were determined. The radioactivity concentration of the muscle corresponded to 2.10% and that of fat to 0.25% of the total dose assuming a value of 30% and 12% of the body weight for these tissues.
For analysis of parent compound and metabolites, milk, muscle, kidney and liver were extracted with mixtures of acetonitrile/water. For milk an additional extraction step with acetone was performed. Fat was extracted with mixtures of n-heptane and acetonitrile/water followed by a solvent partitioning step yielding an n-heptane and an acetonitrile/water phase. No residues were found in the n-heptane phase of fat. The resulting extracts of milk, muscle, fat, kidney and liver represented between 92.9% and 99.8% of the total radioactive residue. Unextractable residues in milk, muscle and fat were below 0.002 mg/kg. For kidney and liver they were 0.021 mg/kg and 0.086 mg/kg, respectively.
After purification and concentration, the extracts were analysed by HPLC with radiometric detection. The HPLC profiling method was based on the use of a reversed phase column and a neutral water/acetonitrile gradient. The metabolite pattern of the extracts of the current goat study and the goat study with the furanone label (study 2, see below) were comparable with the exception of the label specific metabolites.
All prominent metabolites of the extracts of milk, muscle, fat, kidney and liver were also detected in urine. Therefore, the isolation and identification of metabolites were performed using the urine samples. Isolated metabolites were identified by LC-MS/MS and used as radiolabelled reference compounds for the identification in milk, muscle, fat, kidney and liver by HPLC co-chromatography. The identification of the minor metabolite BYI 02960-AMCP-difluoroethanamine was performed in the liver by HPLC co-chromatography with the non-radiolabelled reference compound.
Approximately 99% of the total radioactivity in milk, muscle, fat and kidney and ca. 93% in liver was identified. All other residues were characterised by their extraction behaviour. The unchanged parent

compound was by far the major constituent of the residue in milk, organs and tissues and amounted to 0.165 mg/kg (88.8%) for milk, 0.349 mg/kg (98.0%) for muscle, 0.105 mg/kg (99.2%) for fat, 0.650 mg/kg (34.8%) for kidney and 1.028 mg/kg (84.6%) for liver.

Extensive metabolism was detected in the kidney, where the main portion of metabolites was found. The major metabolite in the kidney was BYI 02960-OH, with a concentration of 0.299 mg/kg (16.0%). Four prominent glucuronic acid conjugates of the hydroxylated parent compound were detected in the kidney as well as in the urine. The four isomers were named BYI 02960-OH-gluA (isomer 1 to isomer 4); their concentration ranged from 0.112 mg/kg (6.0%) to 0.175 mg/kg (9.3%). BYI 02960-OH-gluA (isomer 2) and BYI 02960-OH-gluA (isomer 3) are diastereomers, which are hydroxylated and conjugated in the 5-position of the furanone ring. BYI 02960-OH-gluA (isomer 4) is hydroxylated and conjugated in the difluoroethyl side chain of the molecule and BYI 02960-OH-gluA (isomer 1) in an unknown position.

A further metabolite was BYI 02960-hippuric acid, which was detected in milk (0.017 mg/kg, 9.1%) and kidney (0.178 mg/kg, 9.5%). Traces of BYI 02960-hippuric acid were also found in the liver (0.010 mg/kg, 0.8%). BYI 02960-cysteinyl-nicotinic acid was identified in the kidney (0.114 mg/kg, 6.1%) and in the liver (0.058 mg/kg, 4.8%). Minor identified metabolites were BYI 02960-methylthio-glyoxylic acid in milk and muscle and BYI 02960-AMCP-difluoroethanamine in kidney and liver. The concentration of each was below 0.020 mg/kg.

The concentration of the total radioactivty (expressed as mg a.s. equiv. /kg) as well as the distribution of the parent compound and metabolites and the identification rates in milk and edible tissues are summarised in the table 7.2.3-03

Table 7.2.3-01 Distribution of residues in milk, muscle, fat, liver and kidney of lactating goats following oral administration of 5 daily doses of [pyridinylmethyl-^{14}C] BYI02960 at a dose rate of 0.92 mg/kg

The metabolic reactions of [pyridinylmethyl-14C-]BYI 02960 in the lactating goat are:

- Hydroxylation followed by conjugation with glucuronic acid forming two diastereomeric conjugates of BYI 02960-OH (BYI 02960-OH-gluA, isomer 2 and 3), the hydroxylation and conjugation being in the 5-position of the furanone ring. One isomer (BYI 02960-OH-gluA, isomer 4) with hydroxylation and conjugation in the difluoroethyl side chain and one isomer (BYI 02960-OH-gluA, isomer 1) with hydroxylation and conjugation in an unknown position
- Oxidative cleavage of the pyridinylmethyl bridge forming BYI 02960-6-CNA followed by conjugation with glycine to form BYI 02960-hippuric acid
- Substitution of the chlorine atom of BYI 02960 with glutathione followed by degradation resulting in the conjugate BYI 02960-cysteine
- Oxidative cleavage of the pyridinylmethyl bridge of BYI 02960-cysteine forming BYI 02960-cysteinyl-nicotinic acid
- Further degradation of BYI 02960-cysteine in the cysteine group and the furanone ring forming BYI 02960-methylthio-glyoxylic acid
- Cleavage of the furanone ring forming BYI 02960-AMCP-difluoroethanamine
- Cleavage of the difluoroethyl group forming BYI 02960-des-difluoroethyl

Study design

The metabolism and excretion of [furanone-4-^{14}C]BYI 02960 (common name: flupyradifurone) were investigated in the lactating goat. The goat (bodyweight 55 kg) was orally dosed once daily for five consecutive days in the morning after milking with 1.0 mg of the active substance per kg body weight (3.50 MBq/mg after radiodilution) which corresponded to 28.82 mg a.s. /kg dry feed/day ~~(11N)~~. The animal was sacrificed about six hours after the last administration. Total radioactive residues (TRR) were determined in milk and excreta at various sampling intervals, and in muscle, fat, kidney and liver

at sacrifice. Milk, edible organs and tissues and urine were analysed for the unchanged parent compound and metabolites.

Results

The overall recovery amounted to 78.94% of the total dose. Much of the remaining radioactivity (ca. 21%) was expected to still be present in the gastro-intestinal tract at sacrifice, due to the short period between the last administration and sacrifice. A significant proportion is probably exhaled as $^{14}CO^2$ since the formation of carbon dioxide had been clearly shown in a rat quantitative whole body autoradiography study using the test compound labelled at the same position (see B.6.1, study 4). An amount of 2.58% of the total dose was secreted with the milk. At sacrifice, the residues in the organs and tissues were calculated or estimated to be 4.22% of the total dose from which about 69% was detected in the skeletal muscle.

Until sacrifice, the excretion of radioactivity accounted for 72.14% of the total dose. A portion of 69.15% was found in the urine and 3.0% in the faeces. The urinary and faecal excretion started immediately after the first administration.

Total Radioactive Residues in Milk, Organs and Tissues

The concentration of radioactivity in milk samples ranged from 0.755 mg/kg at 24 hours to 1.213 mg/kg at 56 hours after the first administration. At sacrifice, the residue concentration was 1.165 mg/kg. The time course in the evening and morning milk pool samples showed a pronounced diurnal pattern. The residues increased significantly during the eight hour period after the second and the fifth administration followed by a decrease measured prior to the delivery of the next dose. A plateau level of about 1.1 mg/kg was reached ca. 50 hours after the first administration.

In the organs and tissues, the highest concentrations were determined in liver (1.746 mg/kg) and kidney (1.472 mg/kg) indicating the significance of these organs for excretion and metabolism. These values corresponded to 0.65% and 0.09% of the total dose, respectively. For muscle and fat 0.539 mg/kg and 0.265 mg/kg, respectively, were determined. The radioactivity concentration of the muscle corresponded to 2.91% and of fat to 0.57% of the total dose assuming a value of 30% and 12% of the body weight for these tissues.

For analysis of parent compound and metabolites, milk, muscle, kidney and liver were extracted with mixtures of acetonitrile/water. Fat was extracted with mixtures of n-heptane and acetonitrile/water followed by a solvent partition yielding an n-heptane and acetonitrile/water phase. Residues in the n-heptane phase of fat amounted to only 0.014 mg/kg (5.4%). The resulting acetonitrile/water extracts of milk, muscle, fat, kidney and liver represented between 73.3% and 95.0% of the total radioactive residue. Solids of kidney and liver were exhaustively extracted with mixtures of acetonitrile/water, 0.1 N HCl and 0.1 N NaOH using microwave assistance. The exhaustive extracts were not further investigated, due to their low amount of residues and/or their high matrix content. Unextractable residues in milk, muscle and fat were low and amounted to ≤0.090 mg/kg. The extraction residues of kidney and liver were completely solubilised after the exhaustive extraction with sodium hydroxide.

After purification and concentration, the conventional acetonitrile/water extracts were analysed by HPLC with radiometric detection. The HPLC profiling method was based on the use of a reversed phase column and a neutral water/acetonitrile gradient. The metabolite pattern of the extracts of the current goat study and the goat study with the pyridinylmethyl label (study 1, see above) were comparable with the exception of the label specific metabolites.

All prominent metabolites of the extracts of milk, muscle, fat, kidney and liver were also detected in urine, except lactose in the milk. Therefore, the assignment of metabolites in the profiles of the extracts was performed based on the comparison with the urine profiles of the current study and the study with the pyridinylmethyl label. Four isomers of BYI 02960-OH-gluA were isolated and identified by comparison of the LC-MS/MS data. Further identification of the BYI 02960-OH-gluA isomers was achieved by comparison of the degradation rates of isomers with the increasing rates of their aglycones and decomposition product, based on the observed decomposition of the isomers in two urine samples. The radioactive lactose in the milk was identified after isolation and acetylation by HPLC co-chromatography with the radiolabelled reference compound.

Approximately 91% of the total residue in milk, ca. 90% in muscle, 83% in fat, 79% in kidney and ca. 60% in liver was identified. All other residues were characterised by their extraction behaviour. The unchanged parent compound was the main constituent of the residue in organs and tissues and amounted to 0.475 mg/kg (88.1%) for muscle, 0.213 mg/kg (80.5%) for fat, 0.744 mg/kg (50.5%) for kidney and 1.045 mg/kg (59.8%) for liver. Lower amounts of parent compound (0.250 mg/kg, 23.9%) were found in the milk. The major part of residues in the milk was radioactive lactose and amounted to 0.698 mg/kg (66.8%). The lactose was specific for the furanone label and was formed by cleavage and subsequent degradation of the furanone ring to smaller carbon units (C-1- or C-2-fragments), which entered the carbon pool of endogenous compounds.

Extensive metabolism was detected in the kidney, where the main portion of metabolites was found. The main metabolite in kidney was BYI 02960-OH (hydroxylation in the 5-position of the furanone ring), which amounted to 0.215 mg/kg (14.6%). Four prominent glucuronic acid conjugates of hydroxylated parent compound were detected in the kidney and in the urine. The four isomers were named BYI 02960-OH-gluA (isomer 1 to isomer 4). Their concentrations were between 0.032 mg/kg (2.2%) and 0.069 mg/kg (4.7%) in the kidney. BYI 02960-OH-gluA (isomer 2) and BYI 02960-OH-gluA (isomer 3) were diastereomers, which were hydroxylated and conjugated in 5-position of the furanone ring. BYI 02960-OH-gluA (isomer 4) was hydroxylated and conjugated in the difluoroethyl side chain and BYI 02960-OH-gluA (isomer 1) in an unknown position. A minor metabolite was BYI 02960-des-difluoroethyl which amounted to 0.019 mg/kg (1.3%) in the kidney.

Metabolites in the polar region of the acetonitrile/water extracts (≤ 5 min) were specific for the furanone label. Their concentrations ranged from 0.021 to 0.037 mg/kg for kidney and from 0.019 to 0.059 mg/kg for liver. These polar metabolites showed the same thin layer chromatographic behaviour as the metabolites, which were detected in the corresponding polar region of rat urine (see B.6.1, study 4) and the extracts of muscle and liver of laying hen (see B.7.2, hen study 2). The polar region of muscle and fat was not further analysed, due to the low amount of radioactivity (≤ 0.024 mg/kg).

The formation of radioactive lactose and polar metabolites was mainly caused by the partial instability of the radiolabel used. For a small portion of the total dose the furanone ring of the molecule obviously underwent extensive biotransformation to C-1- and C-2-fragments resulting in an accumulation of radioactivity in biomolecules during the dosing for five days. A part of these fragments was probably also converted to the terminal product $^{14}CO_2$, which might explain the lower overall recovery as compared to the study with the metabolically stable pyridinylmethyl label.

The concentration of the total radioactivty (expressed as mg a.s. equiv. /kg) as well as the distribution of the parent compound and metabolites and the identification rates in milk and edible tissues are summarised in table 7.2.4-02.

Table 7.2.4-01 Distribution of residues in milk, muscle, fat, liver and kidney of lactating goats following oral administration of 5 daily doses of [furanone-4-^{14}C]BYI 02960 at a dose rate of 0.85 mg/kg

The metabolic and excretion behaviour of [furanone-4-14C]BYI 02960 in the lactating goat can be characterised by the following observations:

- The concentration of radioactivity in milk and edible tissues were relatively high compared to the dose level and the dosing period of five days. This was mainly caused by the partial instability of the radiolabel used. For a small portion of the total dose the furanone ring obviously underwent extensive biotransformation to C1- and C2-fragments that resulted in an accumulation of radioactivity in biomolecules during dosing for five days.
  A part of these fragments was probably also converted to the terminal product $14CO_2$ as can be derived from the lower overall recovery compared to the study with the metabolically stable pyridinylmethyl label.
- However, the fact should be considered that an exaggerated dose level of 28.82 mg/kg feed/day was administered. Furthermore, the significant amount of radioactivity detected in urine and faeces and the relatively high radioactivity in liver and kidney at sacrifice indicate that the residues are further metabolised and finally eliminated.
- The total radioactive residues in milk showed a diurnal pattern after the second administration as they declined significantly prior to the delivery of the next dose. A residue plateau level was reached after the third administration.
- The radioactive residues were efficiently extracted from milk as well as from edible organs and tissues; extraction rates were between 91.4% and 100.0%.

- Parent compound was the main constituent of the residues in muscle (ca. 88%), fat (ca. 81%), kidney (ca. 51%) and liver (ca. 60%). Approximately 24% of the total radioactivity in the milk was identified as parent compound.
- The main residue in the milk was radioactive lactose (approx. 67%)
- Extensive metabolism was detected in the kidney. BYI 02960-OH, four glucuronic acid conjugates of hydroxylated BYI 02960 and BYI 02960-des-difluoroethyl were identified.
    - The main metabolic reactions in the lactating goat are:
    - Cleavage and subsequent degradation of the furanone ring forming small carbon units (C-1- or C-2-fragments), entering the carbon pool of endogenous compounds and finally being used for example for the biosynthesis of lactose
    - Hydroxylation followed by conjugation with glucuronic acid forming two diastereomeric conjugates of BYI 02960-OH (BYI 02960-OH-gluA, isomer 2 and 3) with hydroxylation and conjugation in the 5-position of the furanone ring, one isomer (BYI 02960-OH-gluA, isomer 4) with the hydroxylation and conjugation in the difluoroethyl side chain and one isomer (BYI 02960-OH-gluA, isomer 1) with the hydroxylation and conjugation in an unknown position
    - Cleavage of the difluoroethyl group forming BYI 02960-des-difluoroethyl

B.7.2.2 List of identified compounds

For a full list of metabolites, see Annex I at the end of this chapter.

B.7.2.3 Metabolic pathway

Figure 7.2.3-1: Proposed metabolic pathway of [pyridinylmethyl-14C] BYI02960 in laying hens

Figure 7.2.3-2: Proposed metabolic pathway of [furanone-4-14C] BYI02960 in laying hens

Figure7.2.3-3: Proposed metabolic pathway of [pyridinylmethyl-14C] BYI02960 in the lactating goat

Figure 7.2.3-4: Proposed metabolic pathway of [furanone-4-14C] BYI02960 in the lactating goat

Pigs

The dominating constituent of the residue in the milk and the edible organs and tissues of the goat is the unchanged parent compound. As the main metabolite, the hydroxylated derivative (BYI 02960-OH) was identified mainly in the kidney. Further metabolites in the kidney and partly also in the liver were determined as glucuronide conjugates of BYI 02960-OH and as BYI 02960 hippuric acid which is the glycine conjugate of 6-chloronicotinic acid. All these metabolites also do occur in the rat in significant amounts (KIIA 5.1). A few minor metabolites were found exclusively in the goat. These are BYI 02960 methylthio-glyoxylic acid which occurred in milk and muscle at concentrations below 0.005 mg/kg and BYI 02960 AMCP-difluoroethanamine which was found in kindey and liver also at low concentrations (< 0.020 mg/kg).

The only major goat metabolite which was not found in the rat is BYI 02960 cysteinyl-nicotinic acid. This was found in the kidney (0.114 mg/kg) and the liver (0.058 mg/kg). This compound is formed as a product of a typical detoxification reaction by conjugation of 6-chloronicotinic acid with cysteine under loss of the chlorine atom. The compound is very polar and easily excretable via urine which is supported by the fact that it was only found in kidney and liver but not in the peripheral compartments of muscle or fat. In this context it should also be noted that the lactating goat was dosed at an exaggerated dose level of ca. 24 mg/kg dry feed which is 5 times higher as the 1X dose level in the cattle feeding study.

Taking all these results into consideration, it can be concluded that the ruminant and rat metabolism follow the same metabolic pathway and thus are neither different in extent nor in nature. Furthermore, no sub-structures of known potential toxicological concern became apparent. Thus a pig metabolism study was rendered unnecessary.

B.7.3 Definition of the residue (IIA 6.7.1; IIIA 8.7.1)

B.7.3.1 Definition of the residue in plant material

Metabolism studies have been conducted in five diverse crops (tomato, apple, potato, cotton, and rice) for foliar and soil applications and in confined rotational crops (Swiss chard, turnip, and wheat) after application of flupyradifurone onto bare soil and cultivating of succeeding crops at three plant-back intervals. The plant metabolism studies have shown a reasonably consistent metabolic profile across both foliar and soil application.

The only residues of flupyradifurone that were consistently observed at significant levels across all primary and succeeding crops were the parent compound and DFA, both of which are specific to flupyradifurone use. DFA has currently not been attributed to other active substance than flupyradifurone. If it is demonstrated in future that other sources lead to DFA, setting separate residue definitions will facilitate handling this metabolite. In primary crops, all other major metabolites were detected in individual RACs only, and generally at low concentrations. Only the natural class of

compounds glucose/ carbohydrates, which was formed from the degradation of the furanone moiety and incorporation of ^{14}C into natural plant constituents, was detected in relatively high concentrations.

In confined rotational crops, nine major metabolites were detected besides the parent compound and DFA. However, all of them were detected in individual RACs only, mainly in feed commodities. The major metabolites detected in food commodities were generally at low concentrations, except for glucose/carbohydrates, which are natural compounds, and the metabolites BYI 02960-OH and BYI 02960-OH-glyc, which were also observed in the rat. The metabolite difluoroethyl-amino-furanone (=DFEAF) was also a major metabolite found in Swiss chard RACs in all rotations. Since it was not observed in the rat and the metabolism studies indicated that no other appropriate marker compound was present, BCS included this metabolite in the residue definition for the data collection method.

BYI 02960-difluoroethyl-amino-furanone appeared to be a suitable marker compound for estimating residue levels of other metabolites, if deemed necessary. For the sake of consistency, BCS analysed the samples of all supervised residue trials on target plants and rotational crops for these three compounds. Thus the residue definition for risk assessment for target plants and rotational crops has three constituents: BYI 02960 (parent compound), DFA, and BYI 02960-difluoroethyl-amino-furanone (DFEAF). However, since DFEAF was only present in 11% of analysed samples and in low amounts only, it was not deemd necessary to include this metabolite in the residue definition for risk assessment.

No other metabolite need be included in the residue definition for risk assessment, since it has been shown that none of the metabolites present a risk for the consumer (see B.6.9.6). All metabolites identified in the metabolism studies show either no consumer exposure under realistic conditions or a consumer exposure below the agreed Threshold level of Toxicological Concern (TTC; <1.5 µg/kg bw), or it has been shown that the metabolites are covered by the endpoints derived for the parent compound flupyradifurone (either via additional toxicity testing or their presence in the rat ADME studies).

Residue definition for monitoring:

Results from supervised residue trials show that flupyradifurone and difluoroacitic acid (DFA) are, by far, the most prominent components of the residues in target plants and rotational crops. The residues of metabolite difluoroethyl-amino-furanone (DFEAF) were below the LOQ of 0.01 mg/kg in virtually all samples. Considering these results as well as those from the metabolism studies, the proposed residue definition for monitoring for target plants and rotational crops is:

~~**The sum of parent compound and DFA, expressed in flupyradifurone equivalents.**~~

1) flupyradifurone

2) DFA, expressed as DFA

Separatly

Residues in supervised residue trials and feeding studies were expressed as flupyradifurone. To convert the residue levels found to expressed as DFA, the residue level is corrected using the molecular weight of flupyradifurone (289 g/mol) andDFA (96 g/mol), resulting in a correction factor of 0.33.

Residue definition risk assessment:

For flupyradifurone residues in target plants (primary crops) and rotational crops (succeeding crops), the proposed residue definition for data collection and risk assessment is:

The sum of parent compound flupyradifurone and its metabolites DFA ~~and difluoroethyl-amino-furanone (DFEAF)~~, expressed in flupyradifurone equivalents. A conversion factor is not required to cover the difference between the residue definition for monitoring and risk assessment as both DFA and flupyradifurone are set as ~~part of~~ the residue definition for monitoring ~~and as DFEAF is found in levels below <0.01 mg/kg in supervised residue trials and in rotational crops. In the unprotected lettuce supervised residue trials, DFEAF was <0.01 mg/kg in the majority of the trials (seven in each region), with a maximum of 0.021 mg/kg in one SEU trial and 0.04 mg/kg in one NEU trial. The ratio of flupyradifurone+DFA to DFEAF in mg/kg is 0.01-0.06. In the protected lettuce trials, DFEAF was detected in six trials, in the range of 0.01-0.02 mg/kg. The ratio of flupyradifurone+DFA to DFEAF in mg/kg is 0.003-0.011. Hence, the conversion factor for lettuce is also proposed to be 1.~~

B.7.3.2 Definition of the residue in animal products

The results of the feeding studies conducted in poultry and cattle with flupyradifurone only, show that parent flupyradifurone and metabolite DFA were by far the predominant compounds detected. Since livestock will in practice mainly be exposed to DFA through feed, the peer review meeting TC 107 conclude that a feeding study in poultry and cattle conducted with DFA are required. The residues of the metabolite BYI 02960-acetyl-AMCP were well below the LOQ of 0.01 mg/kg in all animal matrices at the corresponding 1X dose levels; the metabolite BYI 02960-OH was detected in cattle liver and kidney, only (0.011-0.019 mg/kg). However, this metabolite is also a major rat metabolite and therefore its toxicity is covered by the endpoints derived for the parent compound.

Considering these results in combination with those from livestock metabolism conducted with flupyradifurone only, BYI 02960 parent compound and its metabolite DFA (expressed as their sum, in BYI 02960 equivalents) are the proposed constituents for the residue definitions for risk assessment and enforcement in animal matrices.

No other metabolite need be included in the residue definition for risk assessment, since it has been shown that none of the metabolites pose a risk for the consumer (see B.6.9.6). All metabolites identified in the metabolism studies show either no consumer exposure under realistic conditions or a consumer exposure below the agreed Threshold level of Toxicological Concern (TTC; <1.5 µg/kg bw), or it has been shown that the metabolites are covered by the endpoints derived for the parent

compound BYI 02960 (either via additional toxicity testing or their presence in the rat ADME studies).

Residue definition for monitoring:
~~**The sum of parent compound and DFA, expressed in flupyradifurone equivalents.**~~

1) flupyradifurone

2) DFA, expressed as DFA

separatly

This is contrary to the conclusion of Peer Review Neeting TC 107, where it was concluded to maintain the residue definition as it was proposed in the first draft of the DAR. However, for consistency, the residue definitions for monitoring for plants and animal products are attuned.

Residue definition risk assessment:
The sum of Flupyradifurone and metabolite DFA, expressed in flupyradifurone equivalents.

B.7.4 Use pattern

BYI 02960 (common name: flupyradifurone) is intended to be registered in Europe for use in lettuce (protected and unprotected) and in northern Europe for outdoor use in hops. Use pattern (GAP) information is summarized in Table 7.4-01 and Tabel 7.4.-02.

Table 7.4-1 Identification of GAP of intended uses

B.7.6 Residues resulting from supervised trials (IIA 6.3; IIIA 8.3)

B.7.6.1 Methods of analysis applied in the supervised trials

Flupyradifurone residues in lettuce and hops were determined using method 01304 (2010 trials lettuce and hops and 2011 trials hops) or method 01212 (2011 trials lettuce). The methods were validated for the determination of parent BYI 02960 and its metabolites difluoroacetic acid (DFA) and BYI 02960-difluoroethyl-aminofuranone (DFEAF) in crops with high water content (see Volume 3 B.5.2). The respective LOQs for BYI 02960 and its metabolites DFA and DFEAF in lettuce were 0.01, 0.02, and 0.01 mg/kg (all in parent equivalents) yielding a calculated total-residue LOQ of 0.04 mg/kg.. The respective LOQs for the three analytes in hops were 0.1, 0.2, and 0.1 mg/kg (all in parent equivalents), yielding a calculated total-residue LOQ of 0.40 mg/kg.

Lettuce

Concurrent recoveries were run together with the analysis of the samples of lettuce with method 01304. Details of recovery data are shown in table 7.6.1-1. All values were within acceptable ranges.

Table 7.6.1-1: Recovery data for the determination of BYI 02960 and its metabolites difluoroacetic acid (DFA) and BYI 02960-difluoroethyl-aminofuranone (DFEAF) in lettuce with method 01304

Hops

During the conduct of the 2010 studies, both validation and concurrent recoveries of BYI 02960 and its metabolites DFA and DFEAF were obtained from samples of hop cones (green and dried). The validation work was done due to the fact that hops are considered "difficult to analyze" but were not included in the original validation set for method 01304. In 2011, samples were analyzed for concurrent recoveries.

Concurrent recoveries were run together with the analysis of the samples of lettuce with method 01304. Details of recovery data are shown in table 7.6.1-3. Values were within acceptable ranges.

Table 7.6.1-3 Recovery data for the determination of BYI 02960 and its metabolites difluoroacetic acid (DFA) and BYI 02960-difluoroethyl-aminofuranone (DFEA) in hops with method 01304.

B.7.6.2 Supervised residue trials in lettuce

Study 1

Characteristics

reference	:	Schulte, G. 2012a KIIA 6.3.1.1/05	GLP statement	:	yes (certified laboratory); Deviations: none
Type of study	:	Supervised residue trial (Greenhouse Europe)	Guideline	:	EEC 7029/VI/95 rev. 5, appendix B (1997)
Year of execution	:	2010	Dose	:	0.125 kg as/ha
test substance	:	BYI 02960 SL 200 formulation Batch no: 2010-000672	LOQ	:	BYI 02960 : 0.01 mg/kg DFA: 0.02 mg/kg DFEAF : 0.01 mg/kg
Species	:	Lettuce *(Lactuca sativa)*	storage Acceptability	: :	≤ 286 d at -18°C Y

Study design

Five trials in lettuce were performed in the 2010 growing season in the greenhouse in France, Germany, the Netherlands, and Italy. The lettuce varieties used were either head-forming (3 trials) or open leaf (2) varieties. An SL formulation containing 200 g/L BYI 02960 was applied to the crop with two applications at intervals of 10 days (11 days in one trial) at a nominal rate of 0.625 L/ha, corresponding to 125 g/ha BYI 02960 a.s.; the water rate was 400-600 L/ha.

Samples of lettuce heads were taken immediately prior and subsequent to the final application, and at several intervals thereafter (up to 7 days after treatment). The envisaged PHI was 3 days.

Samples were investigated for BYI 02960 and its metabolites DFA and DFEAF using method 01304. The respective LOQs for the 3 analytes were 0.01, 0.02, and 0.01 mg/kg (all in parent equivalents).

Results

On day 0, immediately following the final treatment, residue levels of flupyradifurone in lettuce heads were between 1.5 and 6.7 mg/kg and <0.02 mg/kg for DFA, expressed as DFA. By day 3 — the envisaged PHI — the levels had declined to 1.4-3.5 mg/kg ~~(n=9)~~ for flupyradifurone and to 0.007-<0.02 mg/kg for DFA, expressed as DFA. Residues continued to decrease until day 7, the final sampling event, when levels ranged from ~~0.78-1.8~~ 0.74-1.7 mg/kg flupyradifurone and to 0.007-<0.02 mg/kg for DFA, expressed as DFA.

Details of the trials are presented in table 7.6.2-~~3~~2.

Conclusion

In study 10-2212 five acceptable residue trials in lettuce performed in accordance with the cGAP for greenhouse use have been provided. Relevant residue data for risk assessment, sum of flupyradifurone and DFA, expressed as flupyradifurone for the critical GAP are: 1.42; 1.82; 2.02; 2.53;

3.52 mg/kg; Relevant residue data for MRL setting are: 1.4, 1.8, 2.0, 2.5, 3.5 mg/kg for flupyradifurone and 0.01-<0.02 mg/kg for DFA, expressed as DFA.

Study 2

Characteristics

reference	:	Uceda, L. 2012c KIIA 6.3.1.1/06	GLP statement	:	yes (certified laboratory); Deviations: none
Type of study	:	Supervised residue trial (Greenhouse Europe)	Guideline	:	EEC 7029/VI/95 rev. 5, appendix B (1997)
Year of execution	:	2011	Dose	:	0.125 kg as/ha
test substance	:	BYI 02960 SL 200 formulation Batch no: 2010-007173	LOQ	:	BYI 02960 : 0.01 mg/kg DFA: 0.02 mg/kg DFEAF : 0.01 mg/kg
Species	:	Lettuce (*Lactuca sativa*)	storage Acceptability	: :	≤228 d at -18°C Y

Study design

Four trials in lettuce were performed in the 2011 growing season in the greenhouse in France, Spain, Germany, and Italy. An SL formulation containing 200 g/L BYI 02960 was applied to the crop with two applications at intervals of 10 days (interval in one trial: 9 day); at a nominal rate of 0.625 L/ha, corresponding to 125 g/ha BYI 02960 a.s.; the water rate was 400-600 L/ha. All lettuce varieties used were leafy (open-head) varieties. The volumes of water ranged from 400-600 L/ha.

Samples of lettuce heads were taken immediately prior and subsequent to the final application, and at several intervals thereafter (up 14 days after treatment). The envisaged PHI was 3 days.

Samples were investigated for BYI 02960 and its metabolites DFA and DFEAF using method 01212. The respective LOQs for the 3 analytes were 0.01, 0.02, and 0.01 mg/kg (all in parent equivalents).

Results

On day 0, immediately following the final treatment, residue levels of flupyradifurone in lettuce heads were between 3.0 and 7.~~67~~ mg/kg and between 0.009-0.043 mg/kg for DFA, expressed as DFA. By day 3 — the envisaged PHI — the levels had declined to ~~0.52~~ 0.73-6.0 mg/kg for flupyradifurone and to 0.007-0.02 mg/kg for DFA, expressed as DFA. For flupyradifurone, residues continued to decrease until day 14, the final sampling event, when levels ranged from 0.13-2.6 ~~0.21-2.7~~ mg/kg, residues increased to 0.009-0.043 mg/kg for DFA, expressed as DFA.

Details of the trials are presented in table 7.6.2-~~3~~2.

Conclusion

In study 11-2070 four acceptable residue trials in lettuce performed in accordance with the cGAP for greenhouse use have been provided. Relevant residue data for risk assessment, sum of flupyradifurone and DFA, expressed as flupyradifurone for the critical GAP are : 0.80, 2.2, 2.7 and 6.0

mg/kg. Relevant residue data for MRL setting are: 0.73; 2.1; 2.6; 6.0 mg/kg for flupyradifurone and 0.009; 0.018; 0.023; 0.043 mg/kg for DFA, expressed as DFA.

Study 3

Characteristics

reference	:	Noss & Bauer, 2012 KIIA 6.3.1.1/01	GLP statement	:	yes (certified laboratory); Deviations: none
Type of study	:	Supervised residue trial (Northern Europe)	Guideline	:	EEC 7029/VI/95 rev. 5, appendix B (1997)
Year of execution	:	2010	Dose	:	0.125 kg as/ha
test substance	:	BYI 02960 SL 200 formulation Batch no: 2010-000672	LOQ	:	BYI 02960 : 0.01 mg/kg DFA: 0.02 mg/kg DFEAF : 0.01 mg/kg
Species	:	Lettuce (*Lactuca sativa*)	storage Acceptability	: :	≤ 202 d at -18°C Y

Study design

Five trials in lettuce were performed in the 2010 growing season in Northern Europe (Netherlands, Belgium, France, and Germany). The lettuce varieties used were either closed-head (3 trials) or leafy (2) varieties. An SL formulation containing 200 g/L BYI 02960 was applied to the crop with two applications at intervals of 10 days (9 days in one trial) at a nominal rate of 0.625 L/ha, corresponding to 125 g/ha BYI 02960 a.s.; the water rate was 300-600 L/ha.

Samples of lettuce heads were taken immediately prior and subsequent to the final application, and at several intervals thereafter (up to 7 days after treatment in 2010).

Samples were investigated for BYI 02960 and its metabolites DFA and DFEAF using method 01304. The respective LOQs for the 3 analytes were 0.01, 0.02, and 0.01 mg/kg (all in parent equivalents).

Results

Lettuce heads were taken 9-10 days after the first treatment (before the final treatment) in order to represent a 1-application use with a 10-day PHI, as is envisaged for general agricultural use in northern European fields. Total residue levels of flupyradifurone and DFA were: 0.10, 0.15, 0.22, 0.39 and 0.82 ~~0.11, 0.16, 0.23, 0.40 and 0.83~~ mg/kg.

On day 0, immediately following the 2nd and final treatment, residue levels of flupyradifurone in lettuce heads were between 1.5 and 4.1 mg/kg and <0.02 mg/kg for DFA, expressed as DFA. By day 3 the levels had declined to 0.37-1.0 ~~0.40, 0.61, 0.71, 0.87 and 1.0~~ mg/kg kg for flupyradifurone and to <0.02 mg/kg for DFA, expressed as DFA. For flupyradifurone, residues continued to decrease until day 7, the final sampling event, when levels ranged from 0.21-0.66 ~~0.25-0.69~~ mg/kg, residues increased to 0.01-<0.02 mg/kg for DFA, expressed as DFA.

Details of the trials are presented in table 7.6.2-43.

Conclusion

In study 10-2223 five acceptable residue trials performed in accordance with the cGAP for outdoor use of Northern Europe with a 10-day PHI have been provided with lettuce. Relevant residue data for risk assessment, sum of flupyradifurone and DFA, expressed as flupyradifurone are: 0.10, 0.15, 0.22, 0.39 and 0.82 ~~0.11, 0.16, 0.23, 0.40 and 0.83~~ mg/kg. Relevant residue data for MRL setting are: 0.08, 0.13, 0.20, 0.37 and 0.80 mg/kg for flupyradifurone and <0.02 mg/kg for DFA, expressed as DFA.

The residue trials were not in accordance with the agricultural cGAP for outdoor use in Northern Europe with a 3-day PHI. No samples were taken 3 days after the first application. In case the residue levels before the second treatment would have declined below the LOQ, the residue levels at 3 days after the 2nd treatment could be considered in order to represent a 1-application use with a 3-day PHI. This is however not the case. The trial results at 3 days after the 2nd treatment represent a more critical use, since the first application additionally contributes to the residue levels.

The results from the trials performed with outdoor lettuce in Northern Europe at 3 days after the 2nd treatment, are however valid to determine whether indoor or outdoor uses can be identified as the worst case residue situation. Relevant residue data for risk assessment, sum of flupyradifurone and DFA, expressed as flupyradifurone for the critical GAP of two applications of 0.125 kg as/ha and PHI 3 days are: 0.39, 0.60, 0.70, 0.85 and 1.02 ~~0.40, 0.61, 0.71, 0.87 and 1.0~~ mg/kg.

Moreover, the tested GAP with two applications and a pre-harvest interval of 3 days is the "home and garden" use, which was submitted in parallel and is envisaged for registration shortly after the agricultural use (see the Evaluation Report for Flupyradifurone as an appendix to Vol. 3, B7). Since this field use is more critical than the agricultural field use, it was agreed with the RMS to conduct all field residue trials according to this GAP to identify the most critical consumer exposure and to avoid re-evaluation of MRLs due to this use. Hence, the trials in the DAR are not in accordance with the cGAP in the DAR, but with the cGAP supported in EU for MRL setting.

Study 4

Characteristics

reference	:	Uceda, L. 2012a KIIA 6.3.1.1/02	GLP statement	:	yes (certified laboratory); Deviations: none
Type of study	:	Supervised residue trial (Northern Europe)	Guideline	:	EEC 7029/VI/95 rev. 5, appendix B (1997)
Year of execution	:	2010	Dose	:	0.125 kg as/ha
test substance	:	BYI 02960 SL 200 formulation Batch no: 2010-007173	LOQ	:	BYI 02960 : 0.01 mg/kg DFA: 0.02 mg/kg DFEAF : 0.01 mg/kg
Species	:	Lettuce (*Lactuca sativa*)	storage Acceptability	: :	≤ 150 d at -18°C Y

Study design

Four trials in lettuce were performed in the 2011 growing season in Northern Europe (France, Belgium, and Germany (2)). An SL formulation containing 200 g/L BYI 02960 was applied to the crop

with two applications at intervals of 10 days at a nominal rate of 0.625 L/ha, corresponding to 125 g/ha BYI 02960 a.s.; the water rate was 500-750 L/ha. All lettuce varieties used were leafy (open-head) varieties.

In two trials samples of lettuce heads were taken immediately prior and subsequent to the second application, and at several intervals thereafter. In two other trials samples of lettuce heads were taken immediately prior and several intervals after the first after the second application. The envisaged PHI is 3 days after one application.

Samples were investigated for BYI 02960 and its metabolites DFA and DFEAF using method 01212. The respective LOQs for the 3 analytes were 0.01, 0.02, and 0.01 mg/kg (all in parent equivalents).

Results

Lettuce heads were taken 9-10 days after the first treatment (before the final treatment) in order to represent a 1-application use with a 10-day PHI. On day 0, immediately following the first treatment, total residue levels in lettuce heads were 2.9 and 5.6 mg/kg (measured in two trials). 9-10 days after the first treatment (before the final treatment) total residue levels of flupyradifurone and DFA were 0.13, 0.21, 0.28 and 0.62 ~~, 0.14, 0.22, 0.28 and 0.65~~ mg/kg.

Only in two trials lettuce heads were taken 2 days after the first treatment (8 days before the final treatment) in order to represent a 1-application use with a 3-day PHI. On day 0, immediately following the first treatment, total residue levels of flupyradifurone and DF in lettuce heads were 2.9 and 5.6 mg/kg. Two days after the first treatment (8 days before the final treatment) total residue levels were 2.0 and 2.6 ~~2.7~~ mg/kg.

~~Ten days after the first treatment (before the final treatment) total residue levels of flupyradifurone and DF were 0.14, 0.22, 0.28 and 0.65 mg/kg.~~

On day 0, immediately following the 2nd and final treatment, residue levels of flupyradifurone in lettuce heads were between 2.6 and 3.8 ~~3.9~~ mg/kg and between 0.007 and <0.02 mg/kg for DFA, expressed as DFA. By day 3 the levels had declined to 0.11, 0.43, 1.5 and 2.9 ~~0.14, 0.47, 1.6 and 3.0~~ mg/kg for flupyradifurone and increased to 0.008-0.032 mg/kg for DFA, expressed as DFA. For flupyradifurone, residues continued to decrease until day 14, the final sampling event, when levels ranged from 0.04-0.95 ~~0.047-1.0~~ mg/kg, residues increased to 0.008-0.066 mg/kg for DFA, expressed as DFA.

Details of the trials are presented in table 7.6.2-~~4~~ 3.

Conclusion

In study 11-2082 four acceptable residue trials performed in accordance with the cGAP for outdoor use of Northern Europe with a 10-day PHI have been provided with lettuce. Relevant residue data for

risk assessment, sum of flupyradifurone and DFA, expressed as flupyradifurone are: 0.13, 0.21, 0.28 and 0.62 ~~, 0.14, 0.22, 0.28 and 0.65~~ mg/kg. Relevant residue data for MRL setting are: 0.11, 0.19, 0.25 and 0.57 mg/kg for flupyradifurone and <0.02, <0.02, 0.009 and 0.016 mg/kg for DFA, expressed as DFA.

The residue trials were not in accordance with the agricultural cGAP for outdoor use in Northern Europe with a 3-day PHI. No samples were taken 3 days after the first application. In two trial samples were taken two days after the first treatment. Total residue levels were 2.0 and 2.6 ~~2.7~~ mg/kg. The trial results at 3 days after the 2nd treatment represent a more critical use, since the first application additionally contributes to the residue levels.

The results from the trials performed with outdoor lettuce in Northern Europe at 3 days after the 2nd treatment, are however valid to determine whether indoor or outdoor uses can be identified as the worst case residue situation. Relevant residue data for the critical GAP of two applications of 0.125 kg as/ha and PHI 3 days are: 0.13, 0.46, 1.52 ~~0.14, 0.47, 1.6~~ and 3.0 mg/kg.

Moreover, the tested GAP with two applications and a pre-harvest interval of 3 days is the "home and garden" use, which was submitted in parallel and is envisaged for registration shortly after the agricultural use (see the Evaluation Report for Flupyradifurone as an appendix to Vol. 3, B7). Since this field use is more critical than the agricultural field use, it was agreed with the RMS to conduct all field residue trials according to this GAP to identify the most critical consumer exposure and to avoid re-evaluation of MRLs due to this use. Hence, the trials in the DAR are not in accordance with the cGAP in the DAR, but with the cGAP supported in EU for MRL setting.

Study 5

Characteristics

reference	:	Schoening, R.; Bauer, J. 2011 KIIA 6.3.1.1/03	GLP statement	:	yes (certified laboratory); Deviations: none
Type of study	:	Supervised residue trial (~~Northern~~ Sourthern Europe)	Guideline	:	EEC 7029/VI/95 rev. 5, appendix B (1997)
Year of execution	:	2010	Dose	:	0.125 kg as/ha
test substance	:	BYI 02960 SL 200 formulation Batch no: 2010-000672	LOQ	:	BYI 02960 : 0.01 mg/kg DFA: 0.02 mg/kg DFEAF : 0.01 mg/kg
Species	:	Lettuce (*Lactuca sativa*)	storage Acceptability	: :	≤ 151 d at -18°C Y

Study design

Five trials in lettuce were performed in the 2010 growing season in Southern Europe (France (South), Spain and Italy). The lettuce varieties used were either closed-head (3 trials) or leafy (2) varieties. An SL formulation containing 200 g/L BYI 02960 was applied to the crop with two applications at intervals of 10 days (11 days in one trial) at a nominal rate of 0.625 L/ha, corresponding to 125 g/ha BYI 02960 a.s.; the water rate was 500-700 L/ha.

Samples of lettuce heads were taken immediately prior and subsequent to the second application, and at several intervals thereafter (up to 7 days after treatment).

Samples were investigated for BYI 02960 and its metabolites DFA and DFEAF using method 01304. The respective LOQs for the 3 analytes were 0.01, 0.02, and 0.01 mg/kg (all in parent equivalents).

Results

Lettuce heads were taken 10-11 days after the first treatment (before the final treatment) in order to represent a 1-application use with a 10-day PHI. Total residue levels of flupyradifurone and DFA were: 2x0.06, 0.08, 0.41 and 0.82 ~~2x0.07, 0.09, 0.41 and 0.83~~ mg/kg.

On day 0, immediately following the 2nd and final treatment, residue levels of flupyradifurone in lettuce heads were between 2.6 ~~2.7~~ and 3.8 mg/kg and 0.007-<0.02 mg/kg for DFA, expressed as DFA. By day 3 the levels had declined to levels between 0.40, 0.48, 1.1, 2.1 ~~0.43, 0.53, 1.2, 2.2~~ and 2.7 mg/kg for flupyradifurone and to 0.007-<0.02 mg/kg for DFA, expressed as DFA. For flupyradifurone, residues continued to decrease until day 7, the final sampling event, when levels ranged from ~~0.15-1.4~~ 0.09-1.3 mg/kg, residues increased to 0.007-0.017 mg/kg for DFA, expressed as DFA.

Details of the trials are presented in table 7.6.2-~~5~~4.

Conclusion

In study 10-2213 five acceptable residue trials performed in accordance with the cGAP for outdoor use of Southern Europe with a 10d PHI have been provided with lettuce. Relevant residue data for risk assessment, sum of flupyradifurone and DFA, expressed as flupyradifurone are: 2x0.06, 0.08, 0.41 and 0.82 ~~2x0.07, 0.09, 0.41 and 0.83~~ mg/kg. Relevant residue data for MRL setting are: 2x0.04, 0.05, 0.38 and 0.80 mg/kg for flupyradifurone and 0.007, 2x 0.01 and 2x <0.02 mg/kg for DFA, expressed as DFA.

The residue trials were not in accordance with the agricultural cGAP for outdoor use in Southern Europe with a 3d PHI. No samples were taken 3 days after the first application. As residues did not decline to a level below LOQ 10d after the first application, the residue levels at 3 days after the 2nd treatment cannot be considered as representative of the cGAP with 1 application and PHI 3d. The results at 3 days after the 2nd treatment represents a more critical use, since the first application additionally contributes to the residue levels.

The results from the trials performed with outdoor lettuce in Southern Europe at 3 days after the 2nd treatment, are however valid to determine whether indoor or outdoor uses can be identified as the worst case residue situation. Relevant residue data for risk assessment, sum of flupyradifurone and

DFA, expressed as flupyradifurone for the critical GAP of two applications of 0.125 kg as/ha and PHI 3 days are: 0.42 ~~0.43~~, 0.53, 1.12 ~~1.2~~, 2.2 and 2.7 mg/kg.

Moreover, the tested GAP with two applications and a pre-harvest interval of 3 days is the "home and garden" use, which was submitted in parallel and is envisaged for registration shortly after the agricultural use (see the Evaluation Report for Flupyradifurone as an appendix to Vol. 3, B7). Since this field use is more critical than the agricultural field use, it was agreed with the RMS to conduct all field residue trials according to this GAP to identify the most critical consumer exposure and to avoid re-evaluation of MRLs due to this use. Hence, the trials in the DAR are not in accordance with the cGAP in the DAR, but with the cGAP supported in EU for MRL setting.

Study 6

test substance	:	BYI 02960 SL 200 formulation Batch no: 2010-007173	LOQ	:	BYI 02960 : 0.01 mg/kg DFA: 0.02 mg/kg DFEAF : 0.01 mg/kg
Species	:	Lettuce (*Lactuca sativa*)	storage	:	≤ 183 d at -18°C
			Acceptability	:	Y – for determination of worst case (indoor or outdoor)

Study design

Four trials in lettuce were performed in the 2011 growing season in Southern Europe (France, Spain, Portugal, and Italy). An SL formulation containing 200 g/L BYI 02960 was applied to the crop with two applications at intervals of 10 days at a nominal rate of 0.625 L/ha, corresponding to 125 g/ha BYI 02960 a.s.; the water rate was 500-750 L/ha. All lettuce varieties used were leafy (open-head) varieties

Samples of lettuce heads were taken immediately prior and subsequent to the final application, and at several intervals thereafter (up 14 days after treatment). The envisaged PHI was 3 days.

Samples were investigated for BYI 02960 and its metabolites DFA and DFEAF using method 01212. The respective LOQs for the 3 analytes were 0.01, 0.02, and 0.01 mg/kg (all in parent equivalents).

Results

Lettuce heads were taken 9-10 days after the first treatment (before the final treatment) in order to represent a single application use with a 10d PHI, as is envisaged for general agricultural use in northern European fields. On day 0, immediately following the first treatment, total residue levels of flupyradifurone and DFA in lettuce heads were 5.3 ~~5.4~~ mg/kg (measured in one trial) and 1.8 to 3.4 ~~3.5~~ mg/kg two days after the first treatment (measured in two trials). 9-10 Days after the first treatment

(before the final treatment) total residue levels were 0.14, 0.31, 0.48 and 0.60 ~~0.15, 0.32, 0.49 and 0.61~~ mg/kg.

On day 0, immediately following the 2nd and final treatment, residue levels of flupyradifurone in lettuce heads were between 2.6 ~~2.7~~ and 7.3 ~~7.4~~ mg/kg and 0.007-0.021 mg/kg for DFA, expressed as DFA. By day 3 the levels had declined to 0.35, 0.72, 1.5 and 3.1 ~~0.39, 0.78, 1.6 and 3.2~~ mg/kg for flupyradifurone and increased to 0.01-0.028 mg/kg for DFA, expressed as DFA. For flupyradifurone, residues continued to decrease until day 14, the final sampling event, when levels ranged from 0.033-0.17 ~~0.094-0.3~~ mg/kg, residues increased to 0.013-0.050 mg/kg for DFA, expressed as DFA.

Details of the trials are presented in table 7.6.2-~~5~~4.

Conclusion

In study 11-2071 four acceptable residue trials performed in accordance with the cGAP for outdoor use of Southern Europe with a 10-day PHI have been provided with lettuce. Relevant residue data for risk assessment, sum of flupyradifurone and DFA, expressed as flupyradifurone are: 0.14, 0.31 ~~0.22~~, ~~0.28~~ 0.48 and 0.60 ~~0.65~~ mg/kg. Relevant residue data for MRL setting are: 0.11, 0.29, 0.43 and 0.55 mg/kg for flupyradifurone and 0.010, 0.017 and 2x <0.02 mg/kg for DFA, expressed as DFA.

The residue trials were not in accordance with the cGAP for outdoor use in Southern Europe with a 3d PHI. No samples were taken 3 days after the first application. In two trial samples were taken two days after the first treatment. Total residue levels for risk assessment, sum of flupyradifurone and DFA, expressed as flupyradifurone were 1.8 ~~2.0~~ and 3.4 ~~2.7~~ mg/kg. The trial results at 3 days after the 2nd treatment represent a more critical use, since the first application cumulatively contributes to the residue levels.

The results from the trials performed with outdoor lettuce in Southern Europe at 3 days after the 2nd treatment are however valid to determine whether indoor or outdoor uses with can be identified as the worst case residue situation. Relevant residue data for risk assessment, sum of flupyradifurone and DFA, expressed as flupyradifurone for the critical GAP of two applications of 0.125 kg as/ha and PHI 3 days are: 0.38, 0.76, 1.58 and 3.18 ~~0.39, 0.78, 1.6 and 3.2~~ mg/kg.

Overall conclusion lettuce

Sets of GLP trials were conducted in 2010 and 2011 in Northern and Southern European fields and in greenhouses. Flupyradifurone was applied twice as an SL formulation (BYI 02960 SL 200, containing 200 g/L BYI 02960 a.s.), with 10-day intervals.

Nine acceptable residue trials performed in accordance with the cGAP for greenhouse use have been provided.

For the envisaged outdoor use in Northern and Southern Europe with a 10d PHI the required number of trials are available (nine acceptable trials for each region).

For the envisaged outdoor use in Northern and Southern Europe with a 3d PHI, the residue trials performed with lettuce in Northern and Southern Europe do not represent the agricultural cGAP, but the 'home & garden use", which has a more critical GAP, except for two trials with sampling 2 days after the 1st treatment. No samples were taken 3 days after the first application. However, the results from the trials performed with outdoor lettuce in Northern and Southern Europe at 3 days after the 2nd treatment are valid to determine whether indoor or outdoor uses can be identified as the worst case residue situation.
Since the the home & garden use is the critcal field use that will determine the MRL, the trials represent the most critical EU use, see the Evaluation Report for setting MRLs for flupyradifurone, as an appendix to vol 3, B7.

Based on a comparison of the residue values from field and greenhouse testing and using the same use pattern, it is evident that the greenhouse use yielded higher total residues in lettuce than did the field uses. In the greenhouse trials a highest total residue value (HR) of 6.04 mg/kg was determined. The STMR in these trials was also the highest for any set, at 2.12 mg/kg. See table 7.6.2-1~~2~~.

A comparison of the residue values from field and greenhouse testing using the most critical use pattern (2x125 g as/ha, int. 10d, PHI 3d) is presented in table 7.6.2-1 ~~and an overview of residue data in lettuce in compliance with envisaged uses is presented in table 7.6.2-2.~~

Details of the trials are presented in tables 7.6.2-2~~3~~ to 7.6.2-4~~5~~. Representative total residue levels for agricultural use in the greenhouse after two applications at the PHI of 3 days are underlined.
The minimum required number of trials for crops is 8 for each region where the crop is considered major. All intended crops in this dossier are considered major in their intended use regions. For protected crops (lettuce) the required 8 trials are available. Although for the open field lettuce in Northern and Southern Europe no trails in compliance with the envisaged uses are available, sufficient trials were performed providing evidence that the envisaged greenhouse can be identified as the worst case residue situation. Therefore no further trials are required.

Table 7.6.2-1 Comparison of the residue values from field and greenhouse testing using the most critical use pattern (2x125 g as/ha, int. 10d, PHI 3d).

B.7.6.3 Supervised residue trials in hops

Study 1

Characteristics

reference	:	Noss, G.; Ballmann, A. 2012a KIIA 6.3.1.2/01	GLP statement	:	yes (certified laboratory); Deviations: none
Type of study	:	Supervised residue trial (Northern Europe)	Guideline	:	EEC 7029/VI/95 rev. 5, appendix B (1997)
Year of execution	:	2010	Dose	:	0.120 kg as/ha
test substance	:	BYI 02960 SL 200 formulation Batch no: 2010-000672	LOQ	:	BYI 02960 : 0.1 mg/kg DFA: 0.2 mg/kg DFEAF : 0.1 mg/kg
Species	:	Hops *(Humulus lupulus)*	storage Acceptability	: :	≤ 222 d at -18°C Y

Study design

Four trials in hops were performed in the 2010 growing season in Northern Europe (all in Germany). An SL formulation containing 200 g/L BYI 02960 was applied once to the crop at a nominal rate of 0.6 L/ha, corresponding to 120 g/ha BYI 02960 a.s.; the water rate was 2000-3000 L/ha.

Samples of green hop cones were taken immediately after the final application and at several intervals thereafter (up to 28 days after treatment). The envisaged PHI was 21 days. (In one trial the PHI samples were taken on day 20). In addition to the green cone samples, additional cones were taken at the later sampling intervals (nominally days 14, 21, and 28) and dried according to standard practice, as dry cones are the primary traded commodity from the grower to the market.

Samples were investigated for BYI 02960 and its metabolites DFA and DFEAF using method 01304. The respective LOQs for the 3 analytes were 0.1, 0.2, and 0.1 mg/kg (all in parent equivalents), yielding a calculated total-residue LOQ of 0.40 mg/kg.

Results

The apparent residues in the control samples used for fortification experiments, were below 30% of the LOQ, with the exception for BYI 02960 for the sample material kiln-dried cone (LOQ-level). In this case, recovery was corrected for apparent residue in the control sample.

Analyses of green cones showed that total residue levels generally declined with time. On day 0, immediately following treatment, residue levels in green hop cones were between 0.79 and 1.7 mg/kg By day 21 — the envisaged PHI (samples were taken on day 20 in one trial — the levels had declined to <0.40-0.82 mg/kg. Residues continued to decrease until day 27-28, the final sampling event, when levels ranged from <0.40-0.46 mg/kg.

The residue behaviour was somewhat less predictable in dried cones. Residue levels on day 21 (20 in one trial) ranged from 0.78-1.2 mg/kg. In one of the trials, the residue level at the final sampling interval (28 days) was higher than at the PHI (day 21): 1.6 mg/kg. In the other trials on day 28 (day 27

in one trial), they were lower, at <0.40-0.79 mg/kg. Taking the highest residues at relevant sampling intervals into consideration (either day 21 or 28), residues ranged from 0.78-1.6 mg/kg.

Details of the trials are presented in table 7.6.2-9.

Conclusion

In study 10-2225 four outdoor residue trials in Northern Europe in hops were provided. The dose rate of 0.120 kg as/ha was less than the envisaged use of 0.150 kg as/ha. The deviation from the envisaged use (< 25%) is considered acceptable. Taking the highest residues at relevant sampling intervals into consideration residue data for dried cones (RAC) for the critical GAP are : 0.78, 1.1, 1.2 and 1.6 mg/kg.

Study 2

Characteristics

reference	:	Noss, G.; Ballmann, A. 2012b KIIA 6.3.1.2/02	GLP statement	:	yes (certified laboratory); Deviations: none

test substance	:	BYI 02960 SL 200 formulation Batch no: 2010-007173	LOQ	:	BYI 02960 : 0.1 mg/kg DFA: 0.2 mg/kg DFEAF : 0.1 mg/kg
Species	:	Hops *(Humulus lupulus)*	storage Acceptability	: :	≤ 117 d at -18°C Y

Study design

Four trials in hops were performed in the 2011 growing season in Northern Europe (all in Germany). An SL formulation containing 200 g/L BYI 02960 was applied once to the crop at a nominal rate of 0.75 L/ha, corresponding to 150 g/ha BYI 02960 a.s.; the water rate was 2000-3000 L/ha.

Samples of green hop cones were taken immediately after the final application and at several intervals thereafter (up to 28 days after treatment). The envisaged PHI was 21 days. (In one trial the PHI samples were taken on day 20; in one other, on day 22.) In addition to the green cone samples, additional cones were taken at the later sampling intervals (nominally days 14, 21, and 28) and dried according to standard practice, as dry cones are the primary traded commodity from the grower to the market.

Samples were investigated for BYI 02960 and its metabolites DFA and DFEAF using method 01304. The respective LOQs for the 3 analytes were 0.1, 0.2, and 0.1 mg/kg (all in parent equivalents), yielding a calculated total-residue LOQ of 0.40 mg/kg.

Results

Analyses of green cones showed that total residue levels generally declined with time. On day 0, immediately following treatment, residue levels in green hop cones were between 0.85 and 2.7 mg/kg.

By day 21 — the envisaged PHI (samples were taken on day 20 in one trial and day 22 in one further trial) — the levels had declined to <0.40-0.87 mg/kg. At day 26-28, the final sampling event, levels ranged from 0.40-0.69 mg/kg.

In dried cones in two out of four trials, residue levels at the final sampling interval (28 days) were higher than at the PHI (day 21). Residue levels on day 21 (20 in one trial, 22 in one other) ranged from 0.56-2.4 mg/kg. On day 28 (day 26 in one trial) residue levels ranged from 0.59-2.3 mg/kg. Taking the highest residues at relevant sampling intervals into consideration (either day 21 or 28), residues ranged from 0.61-2.4 mg/kg.

Details of the trials are presented in table 7.6.3-2.

Conclusion

In study 11-2076 four acceptable residue trials performed in accordance with the cGAP for outdoor use of Northern Europe have been provided with hops. Taking the highest residues at relevant sampling intervals into consideration residue data for dried cones (RAC) for the critical GAP are : 0.61, 0.73, 2.3 and 2.4 mg/kg.

Overall conclusion hops

In hops, eight valid trials were conducted in the northern European residue region in the years 2010-2011. Flupyradifurone was applied once as an SL 200 formulation at an active substance rate of 120 - 150 g/ha. All applications were at acceptable rates, and all trials were conducted according to GLP.

To evaluate this use, samples of both green and dried hop cones were taken at several intervals after the final application, including the envisaged PHI of 21 days. Samples were analyzed for the relevant residues of BYI 02960, comprising the parent compound and its metabolites DFA and DFEAF. The residues of all three analytes were summed to yield a calculated "total residue of BYI 02960". The results of the trials presented above demonstrate that:

- total residues of BYI 02960 dissipated rapidly in green hop cones, from levels of 0.79-2.7 mg/kg on day 0 after the treatment to <0.40-0.87 mg/kg on day 21 (envisaged PHI). The respective median values were 1.3 and 0.47 mg/kg;
- in dried cones, residue levels also tended to decline with time. When evaluating the highest residues at relevant sampling intervals (either day 21 or, in three trials, day 28), residues ranged from 0.61-2.4 mg/kg, with a median of 1.15 mg/kg.

An overview of residue data in hops is presented in table 7.6.3-1. Details of the trials are presented in table 7.6.3-2.

Compared to the residue definition for monitoring the metabolite BYI 02960-difluoroethyl-amino-furanon (DFEAF) is included in the residue definition for risk assessment. Since DFEAF was not detected at levels at or above the LOQ of 0.1 mg/kg a conversion factor (monitoring to risk assessment) of 1 is proposed.

Tabel 7.6.3-1 Overview of the available residue trials data in hops.

Commodity	Residue region	Outdoor/ indoor	Enforcement		Risk assessment			MRL proposal (mg/kg)		Median CF	Comments
			BYI 02960	DFA	(Sum of BYI 02960 (parent compound) and DFA, expressed as BYI 02960)	Median residue (mg/kg)	Highest residue (mg/kg)	BYI 02960	DFA

Year of execution	:	2011-2012			
Storage duration	:	18 months	Matrix	:	High acid, high oil, high protein, high starch, high water, specialty matrix (coffee)
Test substance	:	Flupyradifurone, DFA, DFEAF	Acceptability	:	Acceptable

Study design

To determine the freezer storage stability of the relevant residues of flupyradifurone in plant materials, individual 5-g control samples of orange fruit (high acid content), spinach leaves and tomato fruit (high

water content), wheat grain (high starch content), bean seed (high protein content), coffee bean (specific matrix), soybean seed (high oil content), and sugar cane were separately spiked with 5.0 µg of either flupyradifurone parent compound, DFA, or DFEAF. Except for the day-0 analysis, samples were stored in glass containers in a freezer at an average temperature of -23°C for later use. For day-0 analysis, three treated samples of each material were chosen, as well as one control sample of each. Samples were then also analysed after nominal intervals of 1, 2½, 5-6, 12 and 18months. At each of these intervals, two treated samples of each material were removed from storage and analyzed, as well as a control sample and two samples for concurrent recovery. Samples used for concurrent recoveries were prepared at the same time and stored in the same fashion as the control samples, and spiked on the day of analysis.

Flupyradifurone and its metabolites were analytically determined using analytical method 01304 (see B.5.2), which was validated prior to and parallel to the residue analysis of the samples. The LOQ was 0.01 mg/kg for parent and DFEAF and 0.02 mg/kg for DFA in matrices with high water and high acid content and 0.05 mg/kg in all other matrices, expressed in BYI 02960 equivalents. The mean values of the concurrent recovery rates per compound, sample material, and spiking level were in the range of 82-106%, with RSDs in the range of 3-14%.

Results

At day 0, average residue recoveries of BYI 02960 ranged from 91-111% of nominal; of DFEAF ranged from 101-110% of nominal; and of DFA ranged from 79-101% of nominal. In samples analysed after approximately 18 months of frozen storage (556-560 days), the apparent (uncorrected) storage stability recoveries ranged from 89-100% ~~92-113%~~ for BYI 02960, 87-147% ~~111-147%~~ for DFA, and from 80-112% ~~85-104%~~ for DFEAF. The concurrent recoveries (= procedural recovery for freshly spiked control samples) after approx. 18 months ranged from 80-102% for BYI 02960, from 79-107% for DFA and from 83-114% for DFEAF. At all sampling dates and in all sample materials, the relevant components of the residue of BYI 02960 were above 70%. Even in the case of the lower values in the given ranges, there was no evidence of any continued degradation of any of the analytes in any of the sample materials. Thus, all analytes can be considered stable in all relevant plant matrix types for a period of at least 18 months (556 to 560 days).

All storage stability results are summarised below in tables 7.6.3-1 to 7.6.1-3.

Conclusions

During a storage period of 18 months under deep-freezer conditions, the components of the relevant residues of flupyradifurone (including parent compound, DFEAF, and DFA) were stable in orange fruit (high acid content), spinach leaves and tomato fruit (high water content), wheat grain (high starch content), bean seed (high protein content), coffee bean (specific matrix), soybean seed (high oil content), and sugar cane (high water content), representing a wide array of plant-based sample materials. These results validate the residue values reported in supervised field trials and processing studies with respect to storage stability of samples frozen prior to analysis.

Guidelines & Limitations

Some samples (barley green material, straw and grain) in the field rotational crop studies were stored for periods of up to 16-18 months; these periods are covered by the storage stability study.

Animal matrices

The longest storage periods for samples from animal residue studies (feeding studies) are shown in table 7.4.4-5 below:

Table 7.4.4-5: Periods of frozen storage (approx. -15 to -20°C) of animal-based samples (between sampling and analysis) for matrices relevant to this dossier

* analyte group A comprises BYI 02960, BYI 02960-acetyl-AMCP, and BYI 02960-OH
analyte group B comprises DFA

Based on the information presented here, no storage stability data was required for the relevant residues of BYI 02960 in most animal matrices. Only samples with DFA in bovine fat, kidney, liver, muscle, and urine; as well as with BYI 02960, BYI 02960-acetyl-AMCP, and BYI 02960-OH in bovine urine were stored for periods of >1 month.

Year of execution	:	2011-2012			
Storage duration	:	43d	Matrix	:	Bovine fat, kidney, liver and muscle
Test substance	:	DFA Batch no: 2009-000240, purity 99.3% w/w	Acceptability	:	Acceptable

Study design

To determine the freezer storage stability of the relevant residues of flupyradifurone in animal materials, individual control samples of bovine fat, kidney, liver, and muscle were separately spiked with DFA, at a nominal concentration of 0.20 mg/kg. Samples were stored in a freezer at a temperature of -15°C. For day-0 analysis, three treated samples of each material were chosen, as well as one control sample of each. Samples were then analysed after an interval of 43 days, in order to cover the longest period of storage for these matrices in the feeding study. At this interval, two treated samples of each material were removed from storage and analyzed, as well as a control sample and two samples for concurrent recovery. Samples used for concurrent recoveries were prepared at the same time and stored in the same fashion as the control samples, and spiked on the day of analysis.

Urine samples were stored for 33 days between sampling and analysis, this is marginally longer than one month. As the primary purpose of the urine residue values in the feeding study was to elucidate transfer factors for the two main components of the residue [BYI 02960 and DFA], storage stability data is not considered necessary.

DFA was analytically determined using analytical method 01304 (see B.5.2), which was validated prior to and parallel to the residue analysis of the samples. The LOQ of the method was 0.02 mg/kg for DFA in milk, cream, fat, kidney, liver, muscle and urine, expressed in BYI 02960 equivalents. Only for whey the LOQ was 0.05 mg/kg, expressed in BYI 02960 equivalents.
The mean values of the concurrent recovery rates per compound, sample material, and spiking level were in the range of 60-88%, with standard deviations < 10%.

Results

At day 0, average residue recoveries of DFA ranged from 60-86% of nominal. In samples analysed after 43 days of frozen storage, storage stability recoveries, normalized to day 0, ranged from 100-109%. When corrected for concurrent recovery, they ranged from 97-100% There was no evidence of any continued degradation of DFA in any of the sample materials. Thus, it can be considered stable in all relevant animal matrix types over the tested period of 43 days.

All storage stability results are summarised below in table 6.1.1-7.

Table 7.6.4-2: Summary of stability data for deep-frozen samples fortified with DFA – samples fortified at 0.20 mg/kg

Matrix	Storage period (d)	Concurrent recovery (%)	Recovery in stored samples (%)		
			apparent	normalized to day 0	corrected for recovery
bovine fat	0	-	85.8	100	100
	43	87.8	86.0	100.2	98.0
bovine kidney	0	-	68.7	100	100
	43	72.5	72.5	105.5	100
bovine muscle	0	-	65.3	100	100
	43	69.0	69.0	105.6	100
bovine liver	0	-	60.3	100	100
	43	68.0	65.8	109.1	96.7

Conclusions

During a storage period of 43 days under deep-freezer conditions, DFA was stable in bovine fat, kidney, liver, and muscle. These results validate the residue values reported in the cattle feeding study with respect to storage stability of samples frozen prior to analysis.

Guidelines & Limitations

The study is considered acceptable.

B.7.6.5 Summary of storage stability studies

Flupyradifurone DFEAF, and DFA are stable in orange fruit (high acid content), spinach leaves and tomato fruit (high water content), wheat grain (high starch content), bean seed (high protein content), coffee bean (specific matrix), soybean seed (high oil content), and sugar cane (high water content) for at least 18 months when stored frozen.
DFA is stable in animal fat, kidney, liver, and muscle for at least 43 days, when stored frozen.

B.7.7 Effects of industrial processing and/or household preparation (IIA 6.5; IIIA 8.5)

B.7.7.1 Nature of the residue

STUDY 1
Characteristics

Reference	:	Weber, E.; 2011 KIIA 6.5.1 /01	GLP	:	yes
Type of study	:	Hydrolysis study	Guideline	:	European Council Directive 91/414/EEC as amended by Commission Directive 96/68/EC Section 6.5, Subsection 6.5.1. OECD Guideline for the Testing of Chemicals 507 Nature of the Pesticide Residues in Processed Commodities - High Temperature Hydrolysis, adopted 2007-10-16
Year of execution	:	2010	Acceptability	:	Acceptable
Test substance	:	[pyridinylmethyl-^{14}C] flupyradifurone; sample ID: KATH 6301; purity >99% w/w			

Study design

The behaviour of flupyradifurone was studied in buffered drinking water under conditions of processing. The radiolabelled test compound [pyridinylmethyl-^{14}C]BYI02960 was used for the hydrolysis investigations.

One concentration (approx. 1.0 mg/L) of the analyte was prepared in sterilized buffered drinking water and incubated under three representative sets of hydrolysis conditions:

Pasteurisation:	90°C at pH 4 for 20 min
Baking, brewing, boiling:	100°C at pH 5 for 60 min
Sterilisation:	120°C at pH 6 for 20 min

The tests at 90°C and 100°C were carried out by using a dry block heater. The test at 120°C was performed in an autoclave. After termination of each test and cooling to room temperature, the pH value was measured. Three aliquots were again taken from each test solution for the determination of the radioactivity content by Liquid Scintillation Counting (LSC). The identity of the test compound was confirmed by LC-MS/MS. In the test solutions, parent compound was identified by HPLC comparison. The pH values of the test solutions were adjusted to pH 4, pH 5, and pH 6 (each ± 0.1) and remained as required. The temperatures were in the ranges of 90 ± 5°C, 100 ± 5°C and 120 ± 5°C during the test periods.

The applied radioactivity was defined as the amount of radioactivity measured in the samples taken at the beginning of the incubation period.

Results

All material balances were in the range between 97.3 to 104.9%. The material balances demonstrate that no radioactivity dissipated from the test systems.

Chromatograms were identical before and after hydrolysis. The test compound was found in amounts of 100.0% in any test solution after hydrolysis. The identity of the test compound was proven after hydrolysis by HPLC cochromatography with the non radiolabelled reference compound

The test compound BYI 02960 was stable under all conditions of high temperature hydrolysis for simulation of food processing. The following conditions were tested:

- pH 4 / 90°C (20 min) - pasteurisation
- pH 5 / 100°C (60 min) - baking, brewing, and boiling
- pH 6 / 120°C (20 min) - sterilisation

Conclusions

Flupyradifurone stable under all conditions of high temperature hydrolysis for simulation of food processing. The following conditions were tested:

- pH 4 / 90°C (20 min) - pasteurisation
- pH 5 / 100°C (60 min) - baking, brewing, and boiling
- pH 6 / 120°C (20 min) - sterilisation

No hydrolysis products of flupyradifurone were detected above an estimated LOD of 0.5%.

Guidelines & Limitations

The nature of DFA and DFEAF residues was not studied, even though DFA is the predominant residue in plant products apart from parent flupyradifurone. DFA is also the predeominant residue in animal products, apart from flupyradifurone.

The applicant argues that the chemical structure of the metabolite DFEAF is a substructure of the parent compound. All functional groups, chemical moieties and their constitution of DFEAF are also present in the chemical structure of the parent compound. Therefore the chemical stability DFEAF is covered by studies with the parent compound. As parent compound was proved to be stable under the processing conditions, it is concluded that this is also true for DFEAF. In addition, in almost all uses worldwide – and certainly in all EU-relevant uses – DFEAF does not play any significant role in the field residues, generally comprising <5% of the total residue.

Due to the similarity of the chemical structures, the properties of DFA (= difluoroacetic acid) can be interpolated from the properties of TFA (= trifluoroacetic acid) and HOAc (acetic acid). The latter compounds are very common in organic chemistry, have often been used in chemical synthesis and many properties have been investigated. It can be deduced from literature data that these two compounds are stable under the conditions to be tested in a processing study. By interpolation of these properties, it is concluded that DFA is also stable under the processing conditions.

RMS agrees with this and no nature of the residue study is required for DFEAF and DFA.

B.7.7.2 Effects on residue levels

STUDY 1
Characteristics

Reference	:	Schulte, G. & Bauer, J.; 2012a KIIA 6.5.4 /01	GLP	:	Yes
Type of study	:	Follow-up study	Guideline	:	EU Council Directive 91/414/EEC amended by Commission Directive 96/68/EC EU Guidance Working Document 7035/VI/95 rev. 5 OECD Guideline for the Testing of Chemicals No. 508, Magnitude of the Pesticide Residues in Processed Commodities EPA Ref. OPPTS 860.1500, Crop Field Trials
Test substance	:	BYI 02960 SL 200 formulation Batch no: 2010-000672			
Year of execution	:	2010	Acceptability	:	Acceptable

Study design

Four trials were conducted in the northern European residue region, in Germany (2), the Netherlands, and Belgium, in order to determine the total residues of BYI 02960 in unprocessed lettuce heads and then in washed and unwashed commodities including external and internal leaves

The field trials were conducted as part of study 10-2223 (see table 7.6.2-4). Two of the trials were conducted on open-headed lettuces, two on closed-head varieties. BYI 02960 SL 200 was sprayed twice at an application rate of approx. 125 g a.s./ha and a water volume of 300-600 L/ha. The final application was conducted at a pre-harvest interval of 3 days.
After processing, residue analysis was performed according to method 01304 as used in the RAC trials themselves (see B.5.2.). The limits of quantitation were 0.01 mg/kg (BYI 02960 and DFEAF) and 0.02 mg/kg (DFA), expressed in parent compound equivalents, yielding a calculated total-residue LOQ of 0.04 mg/kg, in all matrices. Prior and parallel to the residue analysis, the method was validated by recovery experiments (see table 7.6.1-1), which was considered acceptable.
Lettuce "processing" was designed to simulate typical household kitchen practices in the use and preparation of lettuce for salads.

The complete outer layer of leaves were removed from the heads, yielding outer leaves and inner head parts. From the inner head parts, leaves were separated from the stalk (inner leaves), then washed in standing water (washed inner leaves and washing water).

Results

The total residues of BYI 02960 (parent compound plus DFA and DFEAF) in the harvested heads at day 3 ranged from 0.40-1.0 mg/kg, as summarized previously (see B.7.6.2, study 3). These values were used for the calculation of "processing" factors.

<u>Outer leaves and inner head parts</u>:
The outer leaves were analyzed separately after their removal; the residue levels were from 0.71-

1.8 mg/kg. In the remaining inner head parts, residue levels were considerably lower, at 0.30-0.74 mg/kg.

Based on these values, it is evident that a large proportion of the residues result from surface deposits. The measured residue levels lead to mean "processing" factors of 1.8 for outer leaves and 0.73 for the inner head parts.

Inner leaves and washed inner leaves:

After separation from the stalks, inner leaves samples prior and subsequent to washing. Residue values ranged from 0.08-0.83 mg/kg and 0.29-0.52 mg/kg in the unwashed and washed inner leaves, respectively. In the intermediate product washing water, they were very low, ranging from <0.04-0.05 mg/kg.

These findings indicate that the remainder of the residues are absorbed to a large extent. Washing does not affect them; indeed, the residues are virtually the same in both washed and unwashed leaves (and also essentially as in the inner head parts above). Based on these values, mean "processing" factors of 0.76 and 0.67 can be calculated from lettuce head to unwashed and washed inner leaves, respectively.

The trial data and transfer factors for the total residues of BYI 02960 are summarized below in tables 7.7.2-1 and 7.7.2-2.

Table 7.7.2-2: Mean processing factors from lettuce processing studies

Compound	outer leaves	inner head parts	inner leaves	washed inner leaves	washing water
BYI 02960	1.8	0.72	0.87	0.65	0.02
DFA	n.a.	n.a.	n.a.	n.a.	n.a.

Conclusions

The mean value of total residue "processing" factors for the outer leaves was 1.8, and 0.72 ~~0.73~~ to the inner head parts. Further washing is of little consequence, with mean "processing" factors for unwashed or washed inner leaves of 0.87 ~~0.76~~ and 0.65 ~~0.67~~, respectively. Typical household preparation steps, e.g. for salad preparation, will result in lower total residues of BYI 02960 than in the RAC itself, as the main portion of the residues is in/on the outer leaves.

Study design

Two trials were conducted in Germany in order to determine the total residues of flupyradifurone in green and dried hop cones and then, after processing, in beer as well as the additional processing intermediates hops draff and brewer's yeast.

The field trials were conducted at 3N the normal application rate for hops, in an attempt to ensure that quantifiable residues will be present in the RAC samples. BYI 02960 SL 200 was sprayed once at an application rate of approx. 360 g a.s./ha and a water volume of 3000 L/ha. The application was conducted at a pre-harvest interval of 21 days.

After processing (described below), residue analysis was performed according to method 01304 as used in the RAC trials themselves (see table 7.6.1-2 and B.5.2). The limits of quantitation were 0.1 mg/kg (BYI 02960 and DFEAF) and 0.2 mg/kg (DFA), expressed in parent compound equivalents, yielding a calculated total-residue LOQ of 0.4 mg/kg, in all matrices except beer, in which the LOQs were 10 times lower (0.01 and 0.02 mg/kg; total residue: 0.04 mg/kg).

Preparation of beer:

Beer processing simulated industrial brewing practices. Prior to the addition of hops to the wort, ground malted barley and water were mixed in a mash tun ("mashing"), then the wort was separated from the insoluble malt components ("lautering").

Green hop cones were dried in hop driers, according to standard industrial procedures, then ground and pelletted. Hop pellets were added to the wort, which was then boiled. Subsequently, the flocs were separated via a whirlpool in which the sludge (hops draff) deposited at the bottom of the cone-shaped vessel. After addition of yeast, the mixture was allowed to ferment in bottom-fermentation containers ("primary fermentation", temp. 9°C). As soon as the extract content of the young beer was sufficient, storing began. Before maturation, however, the young beer was cooled.

During the main fermentation, the yeast deposits on the bottom of the tank; this material is sampled (brewer's yeast). The beer is stored under pressure at approx. 2°C for 3-4 weeks. All further sludge-

like materials settle to the bottom. The matured liquid is filtered and then the final product, beer, is sampled.

Limited validation sets and concurrent recoveries of BYI 02960 and its metabolites DFA and DFEAF were obtained from samples of hop matrices (green and dried cones, hops draff, brewer's yeast, and beer). In all matrices except for beer, recovery samples for parent compound and DFEAF were spiked at levels of 0.10 mg/kg and 1.0 mg/kg, as well as 5.0 mg/kg for hop cones (expressed in BYI 02960 equivalents); in beer, spiking levels were 0.01 and 0.10 mg/kg. Mean recoveries in the larger validations sets (n > 2) for all matrices were 81-111%, with RSDs of 1.4-13.9%; n=3-6. Even in the case of values over 110%, these values were considered to be acceptable because they were only marginally higher and the RSD values were very low; also, in the cases of the exceptions, the overall means of all recovery analyses for the given matrices with each individual analyte were 107-108%, with overall RSDs of 4.2-7.1%.

For DFA, concurrent recovery samples for all matrices except beer were spiked at levels of 0.20 mg/kg and 1.0 mg/kg, as well as 5.0 mg/kg for hop cones (expressed in BYI 02960 equivalents); fortification levels in beer were 0.02 and 0.20 mg/kg. Mean recoveries in the larger validations sets (n > 2) in all matrices were 83-109%, with RSDs of 2.6-14.1%; n=3-6. All values were within acceptable ranges.

Results

Beer:

The total residues of BYI 02960 (parent compound plus DFA and DFEAF) in the harvested green cones at day 21 were 0.73 and 1.5 mg/kg. After drying, the values were 3.0 and 5.0 mg/kg. As the dried cone is generally considered to be the "RAC" in the case of hops, all processing factors are based on the residues in the dried commodity.

Residue values in beer were 0.04 and 0.05 mg/kg. Based on these values, a mean transfer factor of 0.01 to beer can be calculated from dried hop cones (0.04 from green cones). Residue levels in all sampled intermediate products (hops draff and brewer's yeast) were below the LOQ of 0.4 mg/kg. All relevant data

All trial data are summarised further below in table 7.7.2-2. The transfer factors for the total residues of BYI 02960 are summarized below in table 7.7.2-3.

Conclusions

The mean value of total residue transfer factors for beer was 0.01. In the intermediates, the average processing factor was <0.1. Thus, for the total residues of BYI 02960, processing to beer will not result in any concentration of the residues.

Guidelines & Limitations

None.

B.7.7.3 Summary of the processing studies

The nature of flupyradifurone residues was studied, revealing that flupyradifurone is stable under all conditions of high temperature hydrolysis.

The nature of DFA and DFEAF residues was not studied, eventhough DFA is the predominant residue in plant products apart from parent flupyradifurone, e.g. DFA was detected up to 0.4 mg/kg in hops. DFEAF was detected up to 0.093 mg/kg in lettuce, however generally DFEAF residues represented <5% of the total residue. DFA is also the predeominant residue in animal products, apart from flupyradifurone. However, a scientificand acceptable argumentation was provided to waive the processing hydrolysis studies for the two metabolites.

Household preparation of lettuce heads, i.e. removing outer leaves and washing the remaning head (separated in inner and outer head) resulted in processing factors of 1.8 for outer leaves, 0.72 ~~0.73~~ for inner head parts and 0.87 ~~0.76~~ for inner leaves.

Using hops in the production of beer, the transfer factors was determined to be 0.01. In the intermediates in the production of beer, the average processing factor was <0.1.

B.7.8 Livestock feeding studies (IIA 6.4; III 8.5)

The test substance used in the study should be representative of the residue in the feedstuffs. In the case of this new insecticide flupyradifurone, by far the major part of the residue in plants is formed by parent flupyradifurone and its metabolite DFA, in varying ratios. Animal metabolism studies show that these two components are also the major contributors to the relevant residue in animals. To cover the needs of all involved countries and regions, several concepts for feeding studies might be applied. After discussion with RMS the Netherlands, it was decided to feed parent flupyradifurone and derive separate transfer factors for the total residue of flupyradifurone + DFA, as well as separately for DFA alone.

Conducting the feeding studies with a mixture of both the parent compound and its primary food/feed-relevant metabolite, DFA, seems attractive when viewed from a 1-region "EU-only" perspective, the feeding studies for the flupyradifurone project (Joint OECD dossier) should be designed to be used in all relevant regions (NAFTA, EU, Brazil and Australia). It is in this point that weaknesses become evident: different crops, different residue levels and compositions, different "feeding tables" used for their evaluation and finally, difficulties in evaluating the results in the long term make this strategy seem less attractive.

Performing separate feeding studies would effectively alleviate the above-mentioned concerns. Dose calculation, result evaluation, and robustness in the face of parameter change are all facilitated by this concept. While it is the most straightforward, precise approach, it would require the use of many more animals.
Seen in this light, the concept of feeding BYI 02960 parent alone and calculating transfer factors for DFA was considered as an acceptable option. While effectively yielding similarly robust data to the two-study solution, only one study for each animal type would be necessary, thus saving animal lives.

While the nature of the calculations/evaluations for the total residue and for parent compound itself are relatively straightforward, using the study data to evaluate the metabolite DFA required careful consideration. As agreed with the RMS, separate transfer factors for DFA were estimated in both the poultry and cattle feeding studies on the basis of the available data after dosage of the active substance flupyradifurone to laying hens and cattle. In order to accomplish this, a theoretical dose of DFA must be estimated in each study. For the estimation of the theoretical dose, the amounts of DFA in all organs/tissues and particularly in the urine (ruminant) or excreta (poultry) must be considered. These absolute residues are representative of the minimum systemic exposure to DFA during the studies and therefore provide the basis for the calculation of a theoretical dose of DFA in the feed.

This, in turn, allows the calculation of transfer factors and, thus, the contribution of DFA to MRLs in animal matrices.

For dietary burden calculations, see table 7.2-2.

B.7.8.1 Ruminants and poultry

Study design

Eighty-four mature laying hens (*Gallus gallus domesticus*) were dosed orally, via capsule, for 29 consecutive days with flupyradifurone at dose rates of 0 mg/kg feed/day (control; 24 hens, 6 subgroups), 1.5 mg/kg feed/day (1.2N group; 0.10 mg as/kg bw/d; 12 hens, 3 subgroups), 6.5 mg/kg feed/day (5.4N ~~4.3N~~ ~~4.9N~~ group; 0.45 mg as/kg bw/d; 12 hens, 3 subgroups; which is approximated a 1X NAFTA dose), 19.4 mg/kg feed/day (16N ~~13N~~ ~~14.7N~~ group; 1.31 mg as/kg bw/d; 12 hens, 3 subgroups; which is approximated a 3X NAFTA dose), and 65.1 mg/kg feed/day (54N ~~43N~~ ~~49N~~ group; 4.54 mg as/kg bw/d; 24 hens, 6 subgroups; which is approximated a 11X NAFTA dose).

The dose rates were adjusted weekly, based on the actual weekly feed consumption by the hens in each dose group during the previous week, resulting in an increase of the fed dose when expressed in mg/kg bodyweight, see table

* dose rate in feed calculated on a dry weight basis
** these weights reflect those determined at the end of the given study week

Eggs were collected twice daily (afternoon and morning prior to the day's dosing). The eggs collected in the afternoon from each sub-group were combined with the eggs collected the following morning from the same sub-group. The egg contents were combined (shells discarded) by sub-group into a labeled container, weighed, and thoroughly mixed by vigorous shaking. Composite egg samples collected on days 0, 2, 4, 7, 10, 14, 17, 21, 24, 28, 35, 42 and 49 were shipped for analysis for the 54N ~~49N~~ dose group; for all other doses, only the egg samples from days 24 and 28 were analyzed.

On day 29 of the study, twelve hens from the control and 54N ~~43N~~ ~~49N~~ dose groups and all hens in the 1.2N, 5.4N ~~4.3N~~ ~~4.9N~~ dose, and the 16N ~~13N~~ ~~4.9N~~ dose groups were sacrificed by CO_2 asphyxiation within 24 hours of the administration of the final dose. Liver (entire), muscle (thigh and breast), and fat (abdominal and subcutaneous) were collected and homogenized in the presence of dry ice.

Twenty four hens (12 from the control group and 12 from the 54N ~~43N~~ ~~49N~~ group) entered into a 21-day depuration phase, (as required for Australia), following the administration of the final dose. Egg and tissue samples were collected on study days 35, 42, and 49 for analysis.

To estimate the extent of exposure of laying hens to DFA following the oral administration of BYI 02960, excreta was also collected daily from all the subgroups of the 5.4N ~~4.3N~~ ~~4.9N~~ and from three of six subgroups of the 54N ~~49N~~ group during the entire dosing period and composited by sub-

group. The entire sample from each sub-group was mixed at the end of the dosing period, and a subsample was homogenized for analysis.

BYI 02960 and its metabolites were analytically determined using analytical method RV-004-A11-04 (see B.5.2.), which was validated prior to and parallel to the residue analysis of the samples. The LOQ was 0.01 mg/kg for all analytes (parent compound, DFA, BYI 02960-acetyl-AMCP, and BYI 02960-OH), expressed in BYI 02960 equivalents.

Table 7.8.1-2: Concurrent recovery data for the relevant residues of BYI 02960 in poultry matrices

Results

The proposed residue definition for both enforcement and risk assessment includes parent flupyradifurone plus DFA, which are by far the two major components of the residue. At sacrifice the following values were determined for the nominal worst-case of 1N for the combined residue of the two components (calculated in the "traditional" manner, i.e. if one component is <LOQ, it is calculated as being *at* the LOQ): 0.093 mg/kg in muscle, 0.039 mg/kg in fat, and 0.11 mg/kg in liver, respectively. In eggs taken on days 24 and 28, total residues in the 1.2N group were 0.061 and 0.057 mg/kg, respectively.
The residues found in the eggs, tissues, and excreta collected from the laying hens during dosing, at the end of the dosing period, and during the depuration phase are presented in tables 7.8.1-3 and 7.8.1-4.

With respect to eggs, the highest total BYI 02960 residues were found in the day-28 eggs from the 54N ~~43N 49N~~ dose group. However, as stated previously, dose rates calculated with respect to mg a.s./kg bw increased during the dosing period (cf. table 7.8.1-2). The residue data from the 54N ~~43N 49N~~ egg samples, when evaluated against the dose rate increases calculated as mg a.s./kg bw, suggest that BYI 02960 residues actually reached a plateau between day 4 and day 7 (see table 7.8.1-3); increases in residue levels appear only to be due to increased dose rates. This estimation is in line with the results of the poultry metabolism studies, in which the plateau level in whole eggs was reached at day 6 (pyridinylmethyl label, B.7.2.1-02) or day 9 (furanone label, B.7.2.2-02).

In the depuration phase, total BYI 02960 residues in eggs, fat, liver, and muscle from the 54N ~~43N 49N~~ dose group hens declined from 1.722, 1.230, 3.480, and 2.410 mg/kg, respectively, to <LOQ at 14 days after cessation of dose administration (=day 42 of the study). The residue data provided in this study are suitable for regulatory purposes. (Depuration data are also presented in tables 7.8.1-3 and 7.8.1-4.)

The levels of DFA residues found in the excreta are summarized in table 7.8.1-6. DFA residues represented 65% to 74% of the total residues of BYI 02960 in the excreta samples, suggesting significant exposure of the laying hens to DFA following the daily oral administration of BYI 02960 to laying hens over 29 days.

** "total BYI 02960 residue" is the sum of BYI 02960, BYI 02960-OH, BYI 02960-acetyl-AMCP, and DFA residues, expressed in BYI 02960 equivalents

† expressed in BYI 02960 equivalents

Conclusion

BYI 02960 was administered orally (via capsule) to laying hens for 29 consecutive days at average dose rates of 1.5 mg/kg feed (1.2N) 6.5 mg/kg feed (5.4N ~~4.3N~~ ~~4.9N~~; which approximated a 1X NAFTA dose), 19.4 mg/kg feed (16N ~~13N~~ ~~14.7N~~), and 65.1 mg/kg feed (54N ~~43N~~ ~~49N~~). Feed consumption, body weights, and egg production were not adversely affected by compound administration.

After the final dose, the animals were sacrificed and the key edible tissues were analyzed for the relevant residues of BYI 02960. While data were generated for four analytes in the study itself, only two – BYI 02960 and DFA – are proposed for the residue definitions (enforcement and risk assessment) for BYI 02960. The combined residues of BYI 02960 + DFA in poultry tissues at sacrifice in the 1N dosing group were 0.093 mg/kg in muscle, 0.039 mg/kg in fat, and 0.11 mg/kg in liver, expressed in parent compound equivalents. Prior to sacrifice, residues in eggs were measured at various intervals in the high-dose group, and on days 24 and 28 in the three lower dose groups. In the 1Ndose group, residues (BYI 02960 + DFA) in eggs amounted to 0.061 and 0.057 mg/kg, respectively.

Residue analysis of the high-dose eggs showed that levels reached a plateau in eggs. Though residues were highest at day 28, residue data from the 54N ~~43N~~ ~~49N~~ egg samples, when evaluated against the dose rate increases calculated as mg a.s./kg bw, suggest that BYI 02960 residues actually reached a plateau between day 4 and day 7; increases in residue levels were only due to increased dose rates. This estimation is in line with the results of the poultry metabolism studies, in which the plateau level in whole eggs was reached at day 6 (pyridinylmethyl label) or day 9 (furanone label).

Depuration occurred quickly. Total BYI 02960 residues in eggs, fat, liver, and muscle from the 54N ~~43N~~ ~~49N~~ dose level hens declined from 1.722, 1.230, 3.480, and 2.410 mg/kg, respectively, to <LOQ at 14 days after cessation of dose administration (=day 42 of the study). The residue data provided in this study are suitable for regulatory purposes.

DFA residues represented 65% to 74% of the total BYI 02960 residues in the excreta samples, suggesting significant exposure of the laying hens to DFA residues following the administration of BYI 02960 for 29 days.

Transfer factors calculated for DFA and the total residue

As agreed with the notifier, separate transfer factors for DFA (difluoroacetic acid) were estimated from the poultry feeding study on the basis of the data available after dosage of the active substance BYI 02960 to laying hens. In order to accomplish this, a theoretical dose of DFA must be estimated. For this estimation, the amounts of DFA in all organs/tissues and particularly in excreta must be considered. The absolute amount of DFA formed in the animals, and which has thus been systemically available, can then be equated with a minimum dose theoretically fed to the animals.

The estimation of the dose of DFA theoretically fed to the animals was conducted on the basis of the data collected for the highest dose group (54N ~~43N~~ ~~49N~~ in EU), using the animals of the subgroups A to C (actual mean dose of BYI 02960 = 65.1 mg/kg feed), see tables 7.8.1-5 and 7.8.1-6.

According to the balance established, the minimum amount of DFA systemically available was 746.2 mg a.s. equiv. for twelve animals (animals of subgroups A, B & C), corresponding to **62.2 mg a.s. equiv. per animal**.

Calculation of transfer factors:

The total amount of BYI 02960 administered in the feeding study accounted for 193.5 mg per animal (4.54 mg/kg bw/day × 1.47 kg bw × 29 days). Thus the total amount of systemically available DFA represented 32.1% of the amount administered as BYI 02960 (62.2 mg/193.5 mg = 32.1%).

Expressing the dose of BYI 02960 in [mg/kg bw/d], the mean dose level in the 54N ~~41N~~ ~~49N~~ dose group accounted for 4.54 mg a.s./kg bw/d. The theoretical dose of DFA can thus be calculated to be **1.46 mg a.s. equiv/kg bw/d** (4.54 mg a.s./kg bw/d × 32.1% = 1.46 mg a.s. equiv/kg bw/d) equal to 20.9 mg a.s./kg dry feed.

On the basis of the DFA residues in eggs and organs/tissues and the theoretical dose of DFA, transfer factors have been calculated, according to the following equation:

$$\textbf{TF} = \frac{\textbf{residue level in edible commodity}}{\textbf{residue level in the diet}}$$

The following tables summarise the residue values determined in the animal matrices and the corresponding transfer factors derived from them.

DFA transfer:

Assuming that the theoretical dose of DFA is reflected by the same proportion (32.1% of the parent dose) for all dose levels, transfer factors for DFA can be estimated at all levels.

It has to be mentioned that, except for the highest dose level, no composite samples of eggs were collected which covered the whole administration phase. Thus for the 1N, 5.4N ~~4.3N~~ and 16N ~~13N~~ ~~12N~~ dose levels, only egg samples from day 28 (the plateau level had been reached by that time) were considered when calculating the transfer.

Table 7.8.1-7: Transfer factors calculated for DFA

Animal matrix	DFA residue [mg a.s equiv./kg]	Transfer factor based on dietary burden in [mg/kg bw/d]	Transfer factor based on dietary burden in [mg/kg dry feed]
Theoretical dose administered: 1.46 mg DFA/kg bw/d = 20.9 mg DFA/kg dry feed (expressed in parent equivalents)			
egg composite* (days 1 to 29)	1.130	0.77	0.054
muscle*	2.270	1.55	0.108

liver	0.104	3.25	0.216

* animals of subgroups A to C were used to calculate the average/weighted residues (*without* "depuration" animals)

Comparing the transfer factors estimated for the animal matrices at different dose levels, it is evident that the transfer of DFA into animal matrices is less pronounced at higher doses. The residue levels in the animal matrices do not increase linearly with the dose levels. The residues detected in eggs and organs/tissues are slightly higher at lower dose levels indicating even more pronounced excretion of DFA at higher dose levels.

Transfer of BYI 02960 residues:

The transfer of the relevant residues of BYI 02960 into edible matrices was also calculated on the basis of the dose administered to the animals in [mg/kg dry feed] or [mg/kg bw/d] and the total residues of BYI 02960 detected in the animal matrices in [mg/kg].

Since the total residue for data collection is different to the relevant residue for enforcement and risk assessment, separate transfer factors were calculated for all animal matrices in all dose groups tested. The total residue as defined for data collection comprises the compounds BYI 02960, BYI 02960-OH,

BYI 02960-acetyl-AMCP, and DFA, wheras only parent compound BYI 02960 and DFA were proposed as relevant residue for enforcement and risk assessment (see B.7.3.2).

The following tables refer to calculations on the basis of the total residue for data collection (BYI 02960, BYI 02960-OH, BYI 02960-acetyl-AMCP and DFA):

Table 7.8.1-8: Transfer factors calculated for the total residue as defined in the data collection method (parent compound BYI 02960, BYI 0296-acetyl-AMCP, BYI 02960-OH and DFA)

Animal matrix	Total residue [mg a.s equiv./kg]	Transfer factor based on dietary burden in [mg/kg bw/d]	Transfer factor based on dietary burden in [mg/kg dry feed]
Average dose administered: 4.54 mg a.s./kg bw/d = 65.1 mg a.s./kg dry feed (54N ~~43N~~ ~~49N~~)			
egg composite* (days 1 to 29)	1.308	0.29	0.020
muscle*	2.409	0.53	0.037
fat*	1.229	0.27	0.019
liver*	3.480	0.77	0.053

liver	0.114	1.14	0.076

* animals of subgroups A to C were used to calculate the average/weighted residues (*without* "depuration" animals)

As was the case for the transfer factors calculated for DFA, the transfer factors for the total residue (either as defined for data collection or for enforcement/risk assessment) are not independent of the dose fed. Higher doses result in a lower transfer of the compounds into the animal matrices. This is in line with the findings that DFA represents the predominant component of the BYI 02960 residues in poultry matrices. Moreover, the "total residue" transfer factors calculated for the lower doses overestimate the transfer of the residues into the animal matrices since all/most components, except for DFA, are well below the LOD in all/most matrices. Although the compounds were not detectable, they were considered to be *at* the LOQ level of 0.01 mg/kg when calculating the total residues. Therefore it is more appropriate to use the transfer factors calculated for parent compound + DFA (relevant residues of BYI 02960 for risk assessment and enforcement) rather than using the transfer factors calculated for the total residue as defined for data collection.

Table 7.8.1-10: Total residues calculated for animal matrices after dosing of BYI 02960 to laying hens

Dose level [mg/kg feed]	Residues [mg a.s. equiv./kg]		
	Animal matrix	**total residue for data collection[1]**	**total residue for enforcement / risk assessment[2]**
1.2N (1.5 mg/kg dry feed)	eggs	0.077	0.057
	fat	0.059	0.039
	liver	0.134	0.114
	muscle	0.113	0.093
5.4N ~~4.3N~~ ~~5N~~ (6.5 mg/kg dry feed)	eggs	0.193	0.173
	fat	0.147	0.127
	liver	0.444	0.423
	muscle	0.320	0.300
16N ~~13N~~ ~~15N~~ (19.4 mg/kg dry feed)	eggs	0.565	0.532
	fat	0.302	0.282
	liver	1.054	1.022
	muscle	0.759	0.729
54N ~~43N~~ ~~49N~~ (65.1 mg/kg dry feed)	eggs	1.308	1.212
	fat	1.229	1.199
	liver	3.480	3.346
	muscle	2.409	2.309

[1] total residue for data collection: BYI 02960, DFA, BYI 02960-acetyl-AMCP and BYI 02960-hydroxy
[2] total residue for enforcement / risk assessment: BYI 02960 and DFA

Remark: All values <LOQ of 0.01 mg/kg were considered as being *at* 0.01 mg/kg to calculate the total residue

It is evident that parent compound BYI 02960 was metabolized rather quickly to DFA after feeding of BYI 02960 to poultry, and quite high amounts of DFA were systemically available. As expected, the highest DFA concentration – and therefore the highest transfer factor – was detected in the metabolizing organ liver, followed by muscle and eggs. However, the transfer of total BYI 02960 residues into all edible matrices is rather low at all dose levels tested.

Feeding of DFA only would thus result in approx. threefold higher transfer factors, as demonstrated above (cf. Table 7.8.1-8). The highest transfer was also determined for liver, followed by muscle and eggs. The lowest transfer factor was determined for fat.

Using these transfer factors derived for the combined residue of BYI 02960 + DFA as well as for DFA alone, estimations of the residue levels reasonably expected to be determined in poultry tissues and eggs after feeding of a mixture of BYI 02960 and DFA (as would realistically be anticipated in the feed crops) can be calculated.

Lactating ruminants

STUDY 1

Characteristics

Type of study	:	Magnitude of residues in animal tissues and animal products (livestock feeding)	GLP statement	:	yes
Year of execution	:	2011-2012	Guideline	:	OPPTS 860.1480 – meat/milk/poultry/eggs OECD Guideline 505 APVMA Residue Guideline No. 23 DACO 7.5 – Meat/milk/poultry/eggs
Test substance	:	Flupyradifurone Batch/Lot Number: 2009-000240, Purity: 99.3%	Dose levels	:	0 – 4.8 – 23 – 50 – 135 mg/kg feed/d
Type of animal	:	Lactating cow (*Bos Taurus*) Holstein dairy cows	Acceptability	:	acceptable

Study design

Twenty Holstein dairy cows (*Bos Taurus*, approximately 2.5 to 3.5 years of age) purchased from a local dairy were dosed orally, via capsule, for 29 consecutive days with flupyradifurone at dose rates of 0 mg/kg feed/day (control; 2 cows), 4.8 mg/kg feed/day (1.6N ~~1.8N~~ ~~2N~~ group; 0.18 mg as/kg bw/d; 4 cows;), 23 mg/kg feed/day (8N ~~9N~~ ~~8N~~ group; 0.90 mg as/kg bw/d; 3 cows; which is approximated a 1X NAFTA dose), 50 mg/kg feed/day (17N ~~19N~~ ~~18N~~ group; 1.84 mg as/kg bw/d; three cows), and 135 mg/kg feed/day (44N ~~52N~~ ~~49N~~ group; 4.90 mg as/kg bw/d; 7 cows).
The animals were dosed orally once per day each morning after milking and feeding.

Milk was collected twice daily (afternoon and morning), and the milk was weighed after each milking. On study days 0, 2, 4, 7, 10, 14, 17, 19, 25, 28, 29, 30, 31, 35, 38, and 42, a subsample of the evening milk was retained (refrigerated) and then composited with the morning milk proportional to the amount collected at each milking. Samples from all of these sampling events were analyzed for the 44N ~~52N~~ group; only day-28 samples were analyzed from the other dose groups. Additional 25-day milk was collected for processing into whey (skim milk) and cream (milk fat) from the one control cow and three of the 44N ~~52N~~ ~~50N~~ dose group cows.

On study day 29, all animals except the four depuration cows were humanely sacrificed at least three hours following the last dose. The depuration cows (44N ~~52N~~ ~~49N~~) were sacrificed on study days 32, 36, and 43 (a control cow was also sacrificed on day 43).

Representative samples of liver (each lobe), kidney (center and ends), fat (approximately equal composite of omental, renal, and subcutaneous), and muscle (composite of loin, round, and flank) were collected. The tissue samples were homogenized in the presence of dry ice and the homogenized samples were placed in a freezer prior to shipping.

To estimate the levels of exposure of dairy cows to DFA residues following administration of BYI 02960, urine was collected from two cows (one each from 1.6N ~~1.8N~~ ~~2N~~ and 44N ~~52N~~ ~~49N~~ dose groups). Starting on study day 1, prior to morning dosing, the 24-hour collected sample from each cow was weighed and a 50-g aliquot was subsampled. (Unfortunately, these samples were not always composited in a manner proportional to the amounts collected. However, since a 24-hour period was always covered, the "inaccuracy" will be negligible.) These subsamples were pooled by week, resulting in one sample per week for four weeks. The samples were frozen prior to shipping and shipped frozen for analysis.

BYI 02960 and its metabolites were analytically determined using analytical method RV-004-A11-04 (see B.5.2), which was validated prior to and parallel to the residue analysis of the samples. The LOQ was 0.01 mg/kg for all analytes (parent compound, BYI 02960-acetyl-AMCP, and BYI 02960-OH) except DFA, for which it was 0.02 mg/kg (0.05 mg/kg in whey). All values are expressed in BYI 02960 equivalents.

Results

The mean values of the concurrent recovery rates per compound, sample material, and spiking level were generally in the range of 70-110%, with very few (and minor) exceptions. As the relative standard deviations were always low – in the range of ~~0~~ 1-13% – all concurrent recoveries were considered to be acceptable. Details of recovery data are shown in table 7.8.1-11.

Feed consumption and milk production were not adversely affected by treatment with BYI 02960. Although some animals gained weight while others lost weight, average body weights decreased slightly in all groups, including the control, but somewhat more in the highest dose group. Thus it appears that 44N ~~52N~~ ~~49N~~ dosing may have had an effect on body weight. One cow in the 44N ~~52N~~ ~~49N~~ group suffered health complications (chronic mastitis, metritis) for which she was treated, but which could not be resolved during the study period. Her condition affected both her feed consumption and body weight, although no effect was evident with respect to milk production.

As the proposed residue definition for both enforcement and risk assessment will include only parent BYI 02960 + DFA, which are by far the two major components of the residue, the critical values for this study may not reflect the total of all components as listed above. In the nominal worst-case dietary burden groups of 1.6N ~~1.8N~~ ~~2N~~, the combined residues of the two components (calculated in the "traditional" manner, i.e. if one component is <LOQ, it is calculated as being *at* the LOQ) were as follows: 0.063 mg/kg in muscle, 0.041 mg/kg in fat, 0.165 mg/kg in liver, and ~~0.180~~ 0.176 mg/kg in kidney, respectively. In milk taken on day 28, total residues in the 1.6N ~~1.8N~~ ~~2N~~ group were 0.043 mg/kg, respectively.

In addition to the general testing, day-25 milk samples from the 44N ~~52N~~ ~~50N~~ dose group were separated into cream and whey, in order to determine if the residues preferentially collect in more aqueous or fatty compartments. The processing/transfer factors (PF) for the total residue (four components) indicated a very slight preference for more aqueous conditions, with a PF of 1.15 to whey and 0.79 to cream. These factors were also representative for the 2 analytes of primary concern, BYI 02960 parent compound and DFA.

The residues found in the milk, tissues, and excreta collected from the dairy cows during dosing, at the end of the dosing period, and during the depuration phase are presented in tables 7.8.1-12 and 7.8.1-13.

With respect to milk, the highest total BYI 02960 residues were found in the day-17 sample from the 44N ~~52N~~ ~~49N~~ dose group. Thus, BYI 02960 residues reached a plateau between at that time and remained at that approximate level for the remainder of the dosing period. The highest total residues in milk at any time in the study in this group were 0.979 mg/kg (total of 4 components); when evaluating only the two analytes of importance, BYI 02960 and DFA, the level was 0.974 mg/kg. This was only slightly higher than 0.886 and 0.806 mg/kg, the values determined in the 44N ~~52N~~ ~~49N~~ group on days 28 and 29, respectively.

In the depuration phase, total BYI 02960 residues in milk, fat, liver, kidney, and muscle from the 50N dose group cows declined from 0.81, 1.40, 1.59, 5.39, and 1.91 mg/kg, respectively, to <LOQ at 6-7 days after cessation of dose administration (=day 35-36 of the study). The residue data provided in this study are suitable for regulatory purposes. Depuration data are also presented in tables 7.8.1-12 and 7.8.1-13.

The levels of DFA residues found in urine are summarized in table table 7.8.1-14. DFA residues represented 6% to 8% of the total residues of BYI 02960 in the urine samples, suggesting low but significant exposure of the dairy cattle to DFA following the daily oral administration of BYI 02960 over 29 days.

Table 7.8.1-124: Proportion of DFA in the total residues of BYI 02960 in urine

Matrix	Dose group	Sampling week	Urine collected (kg)*	Total BYI 02960 residue** (mg/kg)	DFA residues† (mg/kg)	Proportion of DFA in total residue (%)
urine	1.6N ~~1.8N~~ ~~2N~~	week 1	146	1.85	0.112	6
		week 2	122	2.18	0.185	8
		week 3	125	2.24	0.184	8
		week 4	142	1.81	0.142	8
	44N ~~52N~~ ~~49N~~	week 1	226	29.1	1.92	7
		week 2	218	30.8	2.33	8
		week 3	159	46.0	3.71	8
		week 4	152	40.9	3.33	8

* Daily average (determined for each of the four study weeks) was multiplied by 7 days to determine the weekly urine output. Both the 2Nand 50N animals experienced some hose blockages; the urine lost during these events was estimated by the in-life phase facility but is not included

** "total BYI 02960 residue" is the sum of BYI 02960, BYI 02960-OH, BYI 02960-acetyl-AMCP, and DFA residues, expressed in BYI 02960 equivalents

† expressed in BYI 02960 equivalents

Conclusion

BYI 02960 was administered orally (via capsule) to dairy cows for 29 consecutive days at average *actual* dose rates of 4.8 mg/kg feed (1.6N ~~1.8N~~ ~~2N~~ dose), 23 mg/kg feed (8N ~~9N~~ ~~8N~~, which approximated a nominal NAFTA 1N dose), 50 mg/kg feed (17N ~~19N~~ ~~18N~~), and 135 mg/kg feed (44N ~~52N~~ ~~49N~~). Feed consumption, body weights, and milk production were not adversely affected by compound administration.

After the final dose, the animals were sacrificed and the key edible tissues were analyzed for the relevant residues of BYI 02960. While data were generated for four analytes in the study itself, only two – BYI 02960 and DFA – are proposed for the residue definitions (enforcement and risk assessment) for BYI 02960. The combined residues of BYI 02960 + DFA in bovine tissues at sacrifice in the 1.6N ~~1.8N~~ ~~2N~~ dosing group were 0.063 mg/kg in muscle, 0.041 mg/kg in fat, 0.18 mg/kg in kidney, and 0.17 mg/kg in liver, expressed in parent compound equivalents. Prior to sacrifice, residues in milk were measured at various intervals in the high-dose group, and on day 28 in the three lower dose groups. In the 1.6N ~~1.8N~~ ~~2N~~ dose group, the residues (BYI 02960 + DFA) amounted to 0.043 mg/kg.

Residue levels reached a plateau in milk. Highest residue were determined at day 17 in the 44N ~~52N~~ ~~50N~~ milk samples, remaining at similar levels for the remainder of the study.

Depuration occurred quickly. Total BYI 02960 residues in milk, fat, liver, kidney, and muscle from the 44N ~~52N~~ ~~49N~~ dose level cows declined from 0.81, 1.40, 1.59, 5.39, and 1.91 mg/kg, respectively, to <LOQ at 6-7 days after cessation of dose administration (=day 35-36 of the study). The residue data provided in this study are suitable for regulatory purposes.

DFA residues represented 6% to 8% of the total BYI 02960 residues in the urine samples, suggesting low but significant exposure of the dairy cows to DFA residues following the administration of BYI 02960 for 29 days.

Transfer factors calculated for DFA and the total residue

As agreed with the notifier, separate transfer factors for DFA were estimated from the cattle feeding study on the basis of the data available after dosage of the active substance BYI 02960 to lactating cows. In order to accomplish this, a theoretical dose of DFA must be estimated. For this estimation, the amounts of difluoroacetic in all organs/tissues and particularly in urine must be considered. In the rat ADME study, the major amount of the total radioactivity, i.e. > 80% of the dose administered, was excreted via the urine. DFA is a polar compound with a low molecular weight, so it can be assumed that is excreted mainly via the urine. Thus the role of excretion via faeces will be minimal, and this matrix was not considered in the dairy cow balance. The absolute amount of DFA formed in the cows and which was thus systemically available can then be equated with a minimum dose theoretically fed to the animals.

The estimation of the dose of DFA theoretically fed to the animals was conducted on the basis of the data collected for the 44N ~~52N~~ ~~50N~~ dose group, using three animals (non-depuration), and the one animal in this dose group for collection of urine (actual mean dose of BYI 02960 = 135 mg/kg feed), and additionally on the basis of the data collected for the 1.6N ~~1.8N~~ ~~2N~~ dose group animals, and one additional animal dosed at 1.6N ~~1.8N~~ ~~2N~~ for collection of urine (actual mean dose of BYI 02960 = 4.8 mg/kg feed).

Minimum dose theoretically fed to lactating cows:

The residue levels in urine, milk, tissues and organs and the weights of the animal matrices (average weight for one animal) used for the calculation of the minimum theoretical dose are summarized in Table 7.8.1-13 (44N ~~52N~~ ~~50N~~ and 1.6N ~~1.8N~~ ~~2N~~ dose).

Table 7.8.1-135: Calculation of absolute DFA amounts in cattle matrices on the basis of the sample weights and the residues in the samples

Animal matrix	Weight [kg]	DFA residue* [mg a.s. equiv./kg]	Absolute DFA amounts [mg a.s. equiv.]
Actual dose administered: 4.90 mg/kg bw/d = 135 mg/kg dry feed (44N ~~52N~~ ~~49N~~)			
milk composite (day 1-28)	874	0.118[5]	103.13
muscle	162[1]	0.381	61.72
fat	64.9[2]	0.335	21.74
liver	8.1[3]	0.380	3.078
kidneys	1.4[4]	0.512	0.717
urine	754	2.70[5]	2035.8
total (one animal)			**2226.2**
Actual dose administered: 0.18 mg/kg bw/d = 4.8 mg/kg dry feed (1.6N ~~1.8N~~ ~~2N~~)			
milk (day 28)	845	0.004	3.50
muscle	165[1]	0.013	2.09
fat	65.9[2]	0.011	0.75
liver	8.2[3]	0.012	0.10
kidneys	1.4[4]	0.018	0.02
urine	535	0.153[5]	82.10
total (one animal)			**88.56**

* milk and organs/tissues:
average/weighted residues were calculated for the "residue animals" using samples from 44N ~~52N~~ ~~49N~~ dose group (non-depuration) and from animals for the 1.6N ~~1.8N~~ ~~2N~~ dose group
urine:
residues were calculated from samples of the "urine collection" animals " in dose groups 44N ~~52N~~ ~~49N~~ and 1.8N ~~2N~~

[1] total muscle weight was calculated assuming a value of 30%of the mean body weight for this tissue
[2] total fat weight was calculated assuming a value of 12%of the mean body weight for this tissue
[3] total liver weight was calculated assuming a value of 1.5% of the mean body weight for this tissue
[4] total kidney weight was calculated assuming a value of 0.25% of the mean body weight for this tissue
[5] weighted DFA residue value are available in original study report.

According to the balance established, the minimum amount of DFA systemically available was **2226.2 mg a.s. equiv. per animal** in the 44N ~~52N~~ ~~49N~~ dose experiment and **88.6 mg a.s. equiv. per animal** in the 1.6N ~~1.8N~~ ~~2N~~ dose experiment.

Calculation of transfer factors:

44N ~~52N~~ ~~49N~~ dose:

The total amount of BYI 02960 administered in the 44N ~~52N~~ ~~49N~~ dose experiment of the feeding study accounted for 76876 mg per animal (4.9 mg/kg bw/day × 541 kg bw × 29 days). Thus the total amount of DFA being systemically available represented 2.9% of the amount administered as BYI 02960.

The theoretical dose of DFA can thus be calculated as being **0.14 mg a.s. equiv./kg bw/d** (4.90 mg a.s./kg feed × 2.9% = 0.14 mg a.s. equiv./kg bw/d) equal to 3.9 mg a.s. equiv./kg dry feed.

1.6N ~~1.8N~~ ~~2N~~ dose:

The total amount of BYI 02960 administered in the 2Ndose experiment of the feeding study accounted for 2929.5 mg per animal (0.184 mg/kg bw/day × 549 kg bw × 29 days). Thus the total amount of DFA being systemically available represented 3.0% of the amount administered as BYI 02960. This proportion fits very well with the percentage calculated for the 44N ~~52N~~ ~~50N~~ dose (2.9% of the BYI 02960 dose administered).

The theoretical dose of DFA can thus be calculated as being **0.005 mg a.s. equiv./kg bw/d** (0.184 mg/kg bw/day × 3.0% = 0.005 mg a.s. equiv./ kg bw/day) equal to 0.14 mg a.s. equiv./kg dry feed.

On the basis of the DFA residues in milk and organs/tissues and the theoretical dose of DFA, transfer factors have been calculated, according to the following equation:

$$\textbf{TF} = \frac{\textbf{residue level in edible commodity}}{\textbf{residue level in the diet}}$$

The following tables summarise the residue values determined in the animal matrices and the corresponding transfer factors derived from them.

DFA transfer:

Assuming that the theoretical dose of DFA is reflected by the same proportion for all dose levels (as shown for the 44N ~~52N~~ ~~49N~~ and the 1.6N ~~1.8N~~ ~~2N~~ dose), transfer factors for DFA were estimated at all levels. In contrast to the 44N ~~52N~~ ~~49N~~ dose experiment (where weighted residues in milk have been calculated), residues in milk were estimated in all other dose groups on the basis of the 28-day sample, i.e. at a point in time at which the plateau had clearly been reached.

Table 7.8.1-146: Transfer factors calculated for DFA

Animal matrix	DFA residue* [mg a.s equiv./kg]	Transfer factor based on dietary burden in [mg/kg bw/d]	Transfer factor based on dietary burden in [mg/kg dry feed]
Theoretical DFA dose administered: 0.14 mg a.s. equiv./kg bw/d = 3.9 mg/kg dry feed; expressed in parent equivalents (44N ~~52N~~ ~~49N~~)			
milk composite (days 1 to 28)	0.118	0.83	0.030
muscle	0.381	2.68	0.097
fat	0.335	2.36	0.086
liver	0.380	2.67	0.097
kidney	0.512	3.60	0.131
Theoretical DFA dose administered: 0.06 mg a.s. equiv./kg bw/d = 1.45 mg/kg dry feed; expressed in parent equivalents (17N ~~19N~~ ~~18N~~)			
milk (day 28)	0.041	0.74	0.028
muscle	0.136	2.46	0.094
fat	0.099	1.79	0.068
liver	0.132	2.39	0.091
kidney	0.203	3.68	0.140
Theoretical dose administered: 0.03 mg a.s. equiv./kg bw/d = 0.67 mg/kg dry feed; expressed in parent equivalents (8N ~~9N~~ ~~8N~~)			
milk (day 28)	0.016	0.61	0.024
muscle	0.054	2.07	0.081
fat	0.038	1.46	0.057
liver	0.057	2.18	0.085
kidney	0.081	3.10	0.121
Theoretical dose administered: 0.005 mg a.s. equiv./ kg bw/day = 0.14 mg/kg dry feed; expressed in parent equivalents (1.6N ~~1.8N~~ ~~2N~~)			
milk (day 28)	0.004	0.77	0.028
muscle	0.013	2.49	0.088
fat	0.011	2.11	0.079
liver	0.012	2.30	0.086
kidney	0.017	3.26	0.125

* average/weighted residues were calculated using samples from "residue" animals for the 44N ~~52N~~ ~~49N~~ dose group and from animals for the 1.6N ~~1.8N~~ ~~2N~~ dose group, in agreement with calculation of residues in the samples of all other dose groups which consisted of "residue" animals, only. Samples of the "urine collection" (44N ~~52N~~ ~~49N~~ and 1.6N ~~1.8N~~ ~~2N~~) and "depuration" animals (44N ~~52N~~ ~~49N~~) were not included.

Theoretical DFA dose was calculated using the percentage of 2.9%

Comparing the transfer factors estimated for the animal matrices at different dose levels, it is obvious that the transfer factors correspond very well. The transfer factors for all matrices were in a very narrow range, e.g. the transfer factor (based on dietary burden in mg/kg dry feed) for milk ranged from 0.024 to 0.030 and the one for muscle from 0.081 to 0.097. The residue levels in the animal matrices increase linearly with increasing dose levels.

Transfer of BYI 02960 residues:

The transfer of BYI 02960 residues into edible matrices was also calculated on the basis of the dose administered to the animals in [mg/kg bw/d] and [mg/kg dry feed] and the total residue of BYI 02960 detected in the animal matrices in [mg/kg].

Since the total residue for data collection is different from the relevant residue for enforcement and risk assessment, separate transfer factors were calculated for all animal matrices in all dose groups tested. The total residue as defined for data collection comprises the compounds BYI 02960, BYI 02960-OH, BYI 02960-acetyl-AMCP, and DFA, wheras only parent compound BYI 02960 + DFA were proposed as relevant residue for enforcement and risk assessment (see B.7.3.2).

The following tables refer to calculations on the basis of the total residue for data collection (BYI 02960, BYI 02960-OH, BYI 02960-acetyl-AMCP and DFA):

Table 7.8.1-157: Transfer factors calculated for the total residue consisting of parent compound BYI 02960, BYI 0296-acetyl-AMCP, BYI 02960-OH and DFA

Animal matrix	Total residue* [mg a.s equiv./kg]	Transfer factor based on dietary burden in [mg/kg bw/d]	Transfer factor based on dietary burden in [mg/kg dry feed]
Average dose administered: 4.90 mg/kg bw/d = 135 mg/kg dry feed (44N 52N 49N)			
milk composite (days 1 to 28)	0.942	0.20	0.007

milk (day 28)	0.148	0.14	0.006
muscle	0.324	0.34	0.014
fat	0.167	0.17	0.007
liver	0.833 0	0.92	0.036
kidney	0.903	0.99	0.039
Average dose administered: 0.18 mg/kg bw/d = 4.8 mg/kg dry feed (1.6N 1.8N 2N)			
milk (day 28)	0.065	0.16	0.013
muscle	0.085	0.32	0.018
fat	0.062	0.18	0.013
liver	0.195	0.88	0.041
kidney	0.209	1.07	0.043

* average/weighted residues were calculated using samples from "residue" animals for the 44N 52N 49N dose group and from animals for the 1.6N 1.8N 2N dose group, in agreement with calculation of residues in the samples of all other dose groups which consisted of "residue" animals, only. Samples of the "urine collection" (44N 52N 49N

and 1.8N ~~2N~~) and "depuration" animals (44N ~~52N~~ ~~49N~~) were not included.

Remark
All values below the LOQ of 0.01 mg/kg (BYI 02960, BYI 02960-acetyl-AMCP and BYI 02960-OH) or below the LOQ of 0.02 mg/kg (DFA) were considered as being *at* 0.01 or 0.02 mg/kg, respectively, to calculate the total residue.

In the subsequent table, the transfer factors were elucidated for the combined residues of BYI 02960 + DFA (*without* the other analytes), as these two compounds have been proposed as the relevant residues of BYI 02960 in poulty matrices for enforcement and risk assessment (see B.7.3.2).

Table 7.8.1-1~~6~~8: Transfer factors calculated for the total residue consisting of parent compound BYI 02960 + DFA

Animal matrix	Total residue [mg a.s equiv./kg]	Transfer factor based on dietary burden in [mg/kg bw/d]	Transfer factor based on dietary burden in [mg/kg dry feed]
Average dose administered: 4.90 mg/kg bw/d = 135 mg/kg dry feed (44N ~~52N~~ ~~49N~~)

muscle	0.065	0.35	0.013
fat	0.042	0.23	0.009
liver	0.174	0.92	0.036
kidney	0.179	0.98	0.037

* average/weighted residues were calculated using samples from "residue" animals for the 44N ~~52N~~ ~~49N~~ dose group and from animals for the 1.6N ~~1.8N~~ ~~2N~~ dose group, in agreement with calculation of residues in the samples of all other dose groups which consisted of "residue" animals, only. Samples of the "urine collection" (44N ~~52N~~ ~~49N~~ and 1.6N ~~1.8N~~ ~~2N~~) and "depuration" animals (44N ~~52N~~ ~~49N~~) were not included.

Remark:
All values below the LOQ of 0.01 mg/kg (BYI 02960) or below the LOQ of 0.02 mg/kg (DFA) were considered as being *at* 0.01 or 0.02 mg/kg, respectively, to calculate the total residue.

The predominant component of the residues in milk, edible tissues, and organs was parent compound BYI 02960, followed by DFA. The metabolite BYI 02960-acetyl-AMCP was below the LOD in all dose groups, and BYI 02960-OH was detected in the high dose groups only. When calculating the total residue, all constituents of the residue definition are considered. Compounds detected below the LOQ were estimated to be at the LOQ level. Thus the total residue overestimates the proportion of BYI 02960-acetyl-AMCP and BYI 02960-OH, especially at a 1X dose where neither of the two metabolites were detected. Therefore, calculation of transfer factors should be restricted to parent compound + DFA, the constituents of the residue definition for enforcement and risk assessment.

In milk, DFA concentrations were lower than those for parent by a factor of approx. 6 to 7, as soon as the plateau was reached in milk. DFA concentrations in muscle and fat were lower by a factor of approx. 2 to 4, and by a factor of approx. 9 in the metabolizing organs liver and kidney. Clearly, parent compound BYI 02960 was metabolized quite slowly to DFA after feeding BYI 02960 to lactating cows. As soon as DFA was formed, it was distributed equally within the body. Transfer into milk was rather low.

Feeding of DFA only would result in approx. three to tenfold higher transfer factors, as demonstrated above (see Table 7.8.1-14). The highest transfer was also detected into the metabolizing organs liver and kidney, followed by muscle and fat. The lowest transfer factor was determined for milk.

Using these transfer factors derived for the combined residue of BYI 02960 + DFA as well as for DFA alone, estimations of the residue levels reasonably expected to be determined in ruminant tissues and milk after feeding of a mixture of BYI 02960 and DFA (as would realistically be anticipated in the feed crops) can be calculated.

B.7.9 Residues in succeeding or rotational crops (IIA 6.6; III 8.6)

Residue levels reported in the summary texts of this paragraph are reported in accordance with the initially proposed residue definition for risk assessment and monitoring, i.e. the sum of flupyradifurone, DFA and DFEAF and the sym of flupyradifurone and DFA, respectively. Results in the residue trials summary tables were amended to represent the revised residue definitions of DFA, expressedas DFA and flupyraduifurone for monitoring and the sum of flupyradifurone and DFA< expressed as flupyradifurone for risk assessment.

Study design

Multi-crop, multi-plot/plantback field rotational crop residue trials were conducted in Europe, two in the northern and two in the southern residue region, as follows:

In 2010-11, four trials (one each in Germany, the Netherlands, Spain, and southern France) were conducted to support the use of BYI 02960 SL 200 in field-grown, non-perennial crops. A single application was made at a nominal rate of 1 L/ha, corresponding to 200 g/ha BYI 02960 a.s., which reflected the projected rate for soil treatment with BYI 02960 (via irrigation) in arable, non-perennial crops, such as lettuce. Water rates were 300-400 L/ha. Applications were either made to bare soil or to lettuce ("target crop"); in the latter case, the crop was then harvested from the field before further crops were planted. All treatments were made at the scheduled rates. PBIs were calculated as time between application to soil or target crop and the sowing/planting of the succeeding crop.

At various intervals, crops were planted back onto the test area in order to simulate a crop failure ("rotation 1", plant-back interval [PBI] 25-33 days), a second use of the plot in the same year ("rotation 2", PBI 60-200 days), or use of the same plot in the succeeding year ("rotation 3", PBI 260-330 days).

In each rotation, 3 different crops representing different botanical groups were planted: a root crop (carrots or turnips), a leafy crop (lettuce), or cereal crop (barley).

Samples of the rotational crops were taken at their respective harvest times, as well as at one earlier interval (immature RACs for lettuce and root crops, or fodder ["green material"] for barley).

Studies conducted to assess the storage stability of frozen samples demonstrated that the relevant residues of BYI 02960 (including parent compound, BYI 02960-difluoroethyl-amino-furanone, and DFA) were stable during a storage period of 18 months under deep-freezer conditions. Samples of the rotational crops were stored for a period of less than 18 months and are therefore covered by the available storage stability investigations.
Samples were investigated for BYI 02960 and its metabolites DFA and DFEAF using method 01304. The respective LOQs for the 3 analytes were 0.01, 0.02, and 0.01 mg/kg (all in parent equivalents), yielding a calculated total-residue LOQ of 0.04 mg/kg.
In addition to the analysis of BYI 02960, DFA and DFEAF (all expressed as BYI 02960 and summarised up to the total residue of BYI 02960 calc.), residues of 6-chloronicotinic acid were determined as supplemental information, with an LOQ of 0.005 mg/kg expressed as 6-chloronicotinic acid (equivalent to 0.01 mg/kg expressed as BYI 02960).

Results

Concurrent recoveries of BYI 02960 and its metabolites DFA and DFEAF were obtained from samples of carrots, turnips, lettuce, and barley. Recovery data for BYI 02960 in carrots, lettuce, turnips and barley are presented in table 7.9-1. (Validation recoveries were conducted separately.

Root crops:
Concurrent recovery samples for parent compound and DFEAF were spiked at levels of 0.01, 0.10, 0.50, and 1.0 mg/kg (expressed in BYI 02960 equivalents). Mean recoveries in root crop samples (carrot or turnip roots, turnip leaves) were 74-108%, with RSDs of the larger validations sets (n > 2, at the LOQ) of 7.1-16.0%; n = 1-6. All values were within acceptable ranges.

For DFA, concurrent recovery samples were spiked at levels of 0.02, 0.20, 0.50, and 1.0 mg/kg (expressed in BYI 02960 equivalents). Mean recoveries were 84-109%, with RSDs (of the larger validations sets [n > 2]) of 7.4-17.1%; n = 1-6.

Leafy crops:
Concurrent recovery samples for parent compound and DFEAF were spiked at levels of 0.01, 0.10 , 0.50, 1.0 and 5.0 mg/kg (expressed in BYI 02960 equivalents). Mean recoveries in root crop samples (lettuce heads) were 91-105%, with RSDs of the larger validations sets (n > 2) of 2.2-10.7%; n = 2-15.

For DFA, concurrent recovery samples were spiked at levels of 0.02-5.0 mg/kg (expressed in BYI 02960 equivalents). Mean recoveries were 90-98%, with RSDs (of the larger validations sets [n > 2]) of 4.3-10.2%; n = 2-12.

Cereal crops:
Concurrent recovery samples for parent compound and DFEAF were spiked at levels of 0.01, 0.10 and 1.0 mg/kg (expressed in BYI 02960 equivalents). Mean recoveries in cereal crop samples (green material, grain, and straw) were 76-110%, with RSDs of the larger validations sets (n > 2, at the LOQ) of 5.6-9.2%; n = 1-4. All values were within acceptable ranges.

For DFA, concurrent recovery samples were spiked at levels of 0.02, 0.05, 0.20, 0.50, and 1.0 mg/kg (expressed in BYI 02960 equivalents). Mean recoveries were 71-108%, with RSDs (of the larger validations sets [n > 2]) of 3.0-7.1%; n = 1-3.

For 6-CNA, concurrent recovery samples were spiked at levels of 0.005, 0.05 and 0.30 mg/kg for turnips and carrots and 0.005, 0.05 and 0.50 mg/kg for cereal metraices and 0.005, 0.05, 0.30, 0.50 and 2.7 mg/kg for lettuce (expressed in BYI 02960 equivalents). Mean recoveries were 76-109%, with RSDs (of the larger validations sets [n > 2]) of 4.4-16.1%; n = 1-16.

Root crops:

All trial data are summarised in table 7.9-2.

The total residues of BYI 02960 (parent compound plus DFA and DFEAF) in the harvested roots of carrots or turnips were generally highest in the first rotation, i.e. after the shortest plant-back interval (PBI) of 25-30 days, when they ranged at an "intermediate" growth stage (including "early harvest", BBCH 47-49) from 0.05-0.14 mg/kg, and at typical harvest ripeness (BBCH 49) from 0.05-0.12 mg/kg. In one trial, however, the residues in the 3rd and final rotation (PBI 284 days) were slightly higher than in the first rotation, at 0.06 mg/kg compared to 0.05 mg/kg. Thus, highest residues in roots in the entire study ranged from 0.06-0.14 mg/kg (median 0.08 mg/kg).
Residues of 6-CNA were <0.005 mg/kg in all treated samples.

By the third rotation, residues in harvestable roots ranged from <0.04-0.06 mg/kg, with a median value of 0.05 mg/kg.

In turnip tops (=leaves; one trial only), highest residue levels were seen in the first rotation (0.24 mg/kg), but these were not significantly different from those seen in the third rotation (0.21 mg/kg).

Leafy crops:
All trial data are summarised in table 7.9-3.

The total residues of BYI 02960 (parent compound plus DFA and DFEAF) in the harvested heads of lettuce were highest in the first rotation, i.e. after the shortest plant-back interval (PBI) of 25-30 days, when they ranged at an "intermediate" growth stage (from BBCH 41-47, including "early harvest", BBCH 46-47) from 0.06-0.21 mg/kg, and at typical harvest ripeness (BBCH 49) from <0.04-0.16 mg/kg. Thus, highest residues in "marketable" heads in the entire study ranged from <0.04-0.16 mg/kg, with a median value of 0.08 mg/kg.
Residues of 6-CNA were <0.005 mg/kg in all treated samples.

By the third rotation, total residues in lettuce heads ranged from <0.04-0.10 mg/kg (median <0.04 mg/kg).

Cereal crops:
All trial data are summarised in table 7.9-4.

The total residues of BYI 02960 (parent compound plus DFA and DFEAF) in the harvested barley grain were highest in the first rotation, i.e. after the shortest plant-back interval (PBI) of 25-33 days, when they ranged from 0.11-0.65 mg/kg (median 0.35 mg/kg). In one trial, however, no grain samples could be taken due to damage by geese (trial 10-2503-02 1st rotation, Netherlands). Based on the

data from straw, it is clear that the missing trial would have yielded residues well below the highest residues and probably below the current median. Residues in straw from the first rotation ranged from <0.07-0.39 mg/kg, with a median value of 0.12 mg/kg. (The level of residues in straw in the Dutch trial were the lowest of any trial.)
Residues of 6-CNA were <0.005 mg/kg in all grain and green material samples. In the straw samples from the SEU trials, residues declined from 0.01 mg/kg at 218 DALT to 0.006 mg/kg at 419 DALT in the French trial and from 0.02 mg/kg at 233 DALT to <0.005 mg/kg at 363 DALT.

By the third rotation, residues in grain ranged from 0.08-0.39 mg/kg, with a median value of 0.12 mg/kg. In straw, they had dropped to <0.07-0.19 mg/kg (median <0.07 mg/kg).
Early in the respective growing periods of each rotation, samples were also taken of green material (forage). Again, residues were highest in the first rotation, in which they ranged from 0.05-0.41 mg/kg, with a median of 0.10 mg/kg. (Residue levels in green material in the Dutch trial were 0.06 mg/kg, below the median and the 2nd-lowest value in this study.)

Conclusion

In order to support the use in the EU of BYI 02960 in non-perennial crops, four multi-plantback multi-crop rotational crop trials were conducted in Europe (2 each in the northern and southern residue regions) in the years 2010-2011. BYI 02960 was applied once as an SL 200 formulation either to bare soil or to a target crop (lettuce) at an active substance rate of 200 g/ha, the target crop was then harvested, and crops representing 3 different botanical groups (roots, leafy veg., cereals) were planted on the plots at 3 intervals thereafter. All applications were at the required rates, and all trials were conducted according to GLP.

To evaluate the potential residues in following crops, samples of the rotated crops were taken at an intermediate stage and at usual full harvest ripeness. Samples were analyzed for the relevant residues of BYI 02960, comprising the parent compound and its metabolites DFA and DFEAF. The residues of all three analytes were summed to yield a calculated "total residue of BYI 02960". The results of the trials presented above demonstrate that:

- total residues of BYI 02960 in all rotational crops tended to be highest in the first, earliest rotation, i.e. grown after a plant-back interval (PBI) of 25-33 days.
- highest total residues of BYI 02960 in rotational root crops (here: carrot and turnip roots) ranged from 0.05-0.14 mg/kg (median 0.06 mg/kg; n=4). In one trial, residues were also determined in the leaves; the highest measured value was in the first rotation, at 0.24 mg/kg.
- highest total residues of BYI 02960 in marketable rotational leafy crops (here: lettuce) ranged from <0.04-0.16 mg/kg, with a median value of 0.07 mg/kg (n=4).
- Residues of 6-CNA were <0.005 mg/kg in all treated samples, except for barley straw grown in Southern Europe, with a maximum residue level of 0.02 mg/kg in the first rotation.

– in rotated cereals (here: barley), the highest total residues of BYI 02960 in grain ranged from 0.11-0.65 mg/kg. The median value here was 0.35 mg/kg, but only 3 trials could be evaluated as geese ate the grain in the 4th trial. Samples were also taken of the fodder-relevant commodities green material and straw. Residues in straw at harvest were <0.07-0.39 mg/kg (median 0.12 mg/kg; n=4), and in green material taken earlier in the rotation they ranged from 0.05-0.41 mg/kg (median 0.10 mg/kg; n=4).
