reference	:	Schulte, G. 2012b KIIA 6.6.3.1.2/01	GLP statement	:	yes
Type of study	:	Rotational crop - Field trial	Guideline	:	EU Council Directive 91/414/EEC amended by Commission Directive 96/68/EC EU Guidance Working Document 7029/VI/95 rev. 5 OECD Guideline for the Testing of Chemicals No. 504, Residues in Rotational Crops
Year of execution	:	2011	Dose	:	0.125 kg as/ha
test substance	:	BYI 02960 SL 200 formulation Batch no: 2010-007173	LOQ	:	BYI 02960 : 0.01 mg/kg DFA: 0.02 mg/kg DFEAF : 0.01 mg/kg
Species	:	potato	storage Acceptability	: :	81-200d months at -18°C Yes

Study design

A rotational crop program was run for potatoes at 4 locations in 2011 (2 in Northern and 2 in Southern Europe). BYI 02960 was applied 2 times at a level of 125g ai/ha to bare soil, with interval 9-10d. Potatoes were planted ~~30~~ 25-33 DAT and harvested 98-137 DAT. Samples were stored frozen until analysis during 81-200d at temperatures ≤ -18°C.

Residues of BYI 02960 and its metabolites DFA (difluoroacetic acid) and BYI 02960-difluoroethyl-aminofuranone (DFEAF) were determined according to method 01304. Residues of BYI 02960 and its metabolites difluoroacetic acid and BYI 02960-difluoroethylaminofuranone were extracted from the sample materials (approx. 5 g) twice using a mixture of acetonitrile/water (4/1, v/v) with 2.2 mL/L formic acid. The crude extract was cleaned up using a Varian Bond Elute C18 solid phase extraction. After elution of the residues, the extract was mixed with reconstitution solution and an isotopically labelled internal standard solution was added. The residues were quantified by HPLC-MS/MS.

Afterwards the total residue of BYI 02960 was calculated by summing up the individual residues of BYI 02960, difluoroacetic acid and BYI 02960 difluoroethylaminofuranone (each analyte expressed as parent).

Conclusion

Concurrent recoveries have been determined along with the analysis of the processing samples (Table 7.9-3). Recoveries have been determined in tubers and in have been found to be all in the required range of 70-110% ± 20%.

The LOQ of analytical Method 01304 for BYI 02960 parent and BYI 02960-difluoroethylaminofuranone (DFEAF) was 0.01 mg/kg and 0.02 mg/kg for DFA in potato tuber.

Residues have been determined for BYI 02960 parent, DFA and BYI 02960-difluoroethyl-aminofuranone in tubers at harvest. Residues are reported in Table 7.9-4. Residues in control

samples were all < LOQ (results not shown). Residues of BYI 02960 parent and BYI 02960-difluoroethylaminofuranone were always <0.01 mg/kg. Instead, only residues of DFA were found at levels of 0.028-0.25 mg/kg (parent equivalent). Thus, in rotational potatoes sampled at harvest, the total residues of BYI 02960 in tubers ranged from 0.048-0.27 mg/kg, with a median value of 0.13 mg/kg (n=4).

STUDY 3

reference	:	Schulte, G. 2012c KIIA 6.6.3.1.3/01	GLP statement	:	yes
Type of study	:	Rotational crop - Field trial	Guideline	:	EU Council Directive 91/414/EEC amended by Commission Directive 96/68/EC EU Guidance Working Document 7029/VI/95 rev. 5 OECD Guideline for the Testing of Chemicals No. 504, Residues in Rotational Crops

test substance	:	BYI 02960 SL 200 formulation Batch no: 2010-007173	LOQ	:	BYI 02960 : 0.01 mg/kg DFA: 0.02 mg/kg DFEAF : 0.01 mg/kg
Species	:	leek	storage Acceptability	: :	61-145d at -18°C Yes

Study design

A rotational crop program was run for leek at 4 locations in 2011 (2 in Northern and 2 in Southern Europe). BYI 02960 was applied 2 times at a level of 125g ai/ha to bare soil, with interval 10-13d. Leek was planted ~~26-33~~ 97-130 DAT and harvested 97-112 DAT (BBCH49). Samples were stored frozen until analysis during 61-145d at temperatures ≤ -18°C.

Residues of BYI 02960 and its metabolites DFA (difluoroacetic acid) and BYI 02960-difluoroethyl-aminofuranone were determined according to method 01304 (also called Method RV-001-P10-02). Residues of BYI 02960 and its metabolites difluoroacetic acid and BYI 02960-difluoroethylaminofuranone were extracted from the sample materials (approx. 5 g) twice using a mixture of acetonitrile/water (4/1, v/v) with 2.2 mL/L formic acid. The crude extract was cleaned up using a Varian Bond Elute C18 solid phase extraction. After elution of the residues, the extract was mixed with reconstitution solution and an isotopically labelled internal standard solution was added. The residues were quantified by HPLC-MS/MS.

Afterwards the total residue of BYI 02960 was calculated by summing up the individual residues of BYI 02960, DFA and BYI 02960 difluoroethylaminofuranone (each analyte expressed as parent).

Conclusion

Concurrent recoveries have been determined along with the analysis of the processing samples (Table 7.9-3). Recoveries have been determined in leek shafts (whole plant without root) and have been found to be all in the required range of 70-110% ± 20%.

The LOQ of analytical Method 01304 for BYI 02960 parent and BYI 02960-difluoroethylaminofuranone was 0.01 mg/kg and 0.02 mg/kg for DFA in leek.

Residues have been determined for BYI 02960 parent, DFA and BYI 02960-difluoroethyl-aminofuranone in leek at harvest. Residues are reported in Table 7.9-4. Residues in control samples were all < LOQ (results not shown). Residues of BYI 02960 parent and BYI 02960-difluoroethyl-aminofuranone were always <0.01 mg/kg. Instead, only residues of DFA were found at levels of 0.020-0.23 mg/kg (parent equivalent). Thus, the total residues of BYI 02960 in leek (whole plant without root) ranged from 0.040-0.25 mg/kg, with a median value of 0.085 mg/kg (n=4).

Concurrent recoveries have been determined along with the analysis of the bulb samples (Table 7.9-3). Recoveries have been determined in dry peas and have been found to be all in the required range of 70-110% ± 20%.

The LOQ of analytical Method 01304 for BYI 02960 parent and BYI 02960-difluoroethylaminofuranone was 0.01 mg/kg and 0.02 mg/kg for DFA in oilseed rape.

Residues have been determined for BYI 02960 parent, DFA and BYI 02960-difluoroethyl-aminofuranone in rape seeds at harvest. Residues are reported in Table 7.9-4. Residues in control samples were all < LOQ (results not shown). Residues of BYI 02960 parent and BYI 02960-difluoroethylaminofuranone were always <0.01 mg/kg. Residues of DFA ranged from 0.05 to 0.15 mg/kg (parent equivalents). Thus, the residues of the total residue of BYI 02960 in rape seeds ranged from 0.070–0.17 mg/kg, with a median value of 0.101 mg/kg (n=4).

Table 7.9-3: Concurrent recoveries for BYI 02960 in rotational crop samples (potato, leek, cucumber, onion, French bean, field pea and winter rape)

Guidelines & Limitations

None. The precipitation measured in the French trials is not considered to impact the trial results.

B.7.9.1 Summary of studies in plants (succeeding crops)

In the large-scale field rotational crop trial, using multiple rotations (simulating crop failure, re-use of the field in the same season, and re-use in the following season) and multiple crop groups (a root crop, a leafy crop, and a cereal), it was evident that total residues in all relevant food and feed matrices were generally highest in the first rotation. Residues in *root*, *leafy*, and *cereal* crops due to field re-use ranged from 0.05-0.14 mg/kg, <0.04-0.16 mg/kg, and 0.11-0.65 mg/kg, respectively, in the primary food commodities. In straw and fodder, they were <0.07-0.39 mg/kg and 0.05-0.41 mg/kg, respectively for total of DFA, DFEAF and flupyradifurone,expressed as flupyradifurone.

Since it was evident that residues of flupyradifurone are to be expected in rotational crops, additional rotational crop studies were performed representative for each type of crop at short plant back interval (PBI 30 days) and in accordance with the supported maximum dose rate of 2 × 125 g as/ha. Potatoes, leek, cucumber, onion, bean, peas and winter rape were grown at 2 locations in Northern and at 2 locations in Southern Europe. BYI 02960 and DFEAF levels were always <0.01 mg/kg while soil metabolite DFA was present in all trials except one onion trial. Residues at harvest showed considerable variation which could not be attributed to geographical zone, soil type, pH, organic matter content, and temperature during treatment, rainfall after treatment or growth period (results not shown). Therefore, results for Northern and Southern Europe are considered as one data set with considerable variation.

HRs of DFA were 0.27, 0.25, 0.43, 0.18, 1.1, 2.3 and 0.17 mg/kg in potatoes, leek, cucumber, onion, bean, peas and winter rape, respectively.

In the Expert meeting of November 2014 it was concluded that rotational crop trials should be submitted, conducted at realistic-worst-case plant back intervals with regard to the following crop selected, and providing in addition soil analyses. Proposed MRLs for DFA for rotational crops are provisional, pending the availability of the new data.

B.7.10 Proposed pre-harvest intervals for envisaged use, or withholding periods, in the case of post-harvest uses (IIA 6.8; IIIA 8.8)

The envisaged pre-harvest intervals are as described above under points B.7.4 and B.7.5. For:

- protected lettuce, the critical PHI is 3 days.
- unprotected lettuce, the critical PHI is 3 days.
- hops, the PHI is 21 days.

B.7.11 Community MRLs

Flupyradifurone is a new active substance not on the market in Europe or outside Europe

B.7.12 Proposed EU MRLs and justification for the acceptability of those MRLs (IIA 6.7.2; IIIA 8.7.2)

B.7.12.1 Proposed MRLs

The supported use for flupyradifurone for approval under Reg (EC) 1107/2009 is on lettuce and hops. The notifier proposes the following MRLs; The proposed MRLs are 9 mg/kg for lettuce and 4 mg/kg for hops (kiln-dried). The applicant used a residue definition for monitoring as the sum of flupyradifuone and DFA, expressed as flupyradifurone.

Use of flupyradifurone is expected to result in residues in succeeding crops. MRLs are proposed based on the field rotational crops for succeeding crops:

Brassica vegetables:	0.3 mg/kg
Leafy vegetables:	0.3 mg/kg
Potatoes:	0.7 mg/kg
Root vegetables:	0.3 mg/kg
Bulb vegetables:	0.4 mg/kg
Fruiting vegetables:	1.0 mg/kg
Legume vegetables:	2.0 mg/kg
Stem vegetables:	0.6 mg/kg
Pulses:	6.0 mg/kg
Oilseeds:	0.8 mg/kg
Cereals:	1.5 mg/kg

Furthermore, the applicant applies for a number of EU-MRLs ~~and import tolerances~~ in parallel to the peer review (art 47 of Reg (EC) 1107/2009).

Table 7.12.1-1: Proposed EU-MRLs from uses of BYI 02960 supported in EU ~~and Import tolerances proposed by the Global Joint Review of BYI 02960~~

Commodity	Proposed EC MRL (mg/kg)	~~Proposed import tolerance (mg/kg)~~
~~Citrus fruits~~		~~3~~
~~Almonds~~		~~0.15~~

Bulb vegetables	0.4	~~0.8*~~
Legume vegetables	2	~~10*~~

† proposal depends on whether sweet corn is covered by EU rotational crop value for "cereals" or not

* extrapolation from EU rotational crop data to AUS use pattern

For MRL proposals for animal commodities, results from the transfer factors derived from the livestock feeding studies and the estimated dietary burden for livestock (on the basis of the field residue trials).

The feeding studies performed at or about the 1x rate resulted in the residue levels presented in table 7.12.1-2.

Table 7.12.1-2: Combined residues of BYI 02960 and DFA in poultry and bovine matrices as determined in the feeding studies (1X dose group)

Commodity	Residue levels (mg/kg)		
	combined residue	individual components	
		BYI 02960*	DFA**

kidney	0.179	0.159	<0.02

* LOQ for BYI 02960 = 0.01 mg/kg
† egg value based on the day-24 egg sample
** LOQ for DFA = 0.02 mg/kg, expressed in BYI 02960 equivalents
†† milk value based on the day-28 milk sample

Based on the feeding study results, transfer factors were calculated both for the *combined residue* of BYI 02960 and DFA derived from the feeding of BYI 02960 as well as for *DFA alone* derived from the exposure levels of the hens and cattle to DFA in the feeding studies. Using these transfer factors, estimations of the residue levels reasonably expected to be determined after feeding of a *mixture* of BYI 02960 and DFA, as would be anticipated in the feed crops, can be calculated.

The notifier separated the residues fed into individual components to perform these calculations. A dietary burden of 1.401 mg/kg feed was calculated for chickens and 4.290 mg/kg feed for dairy cows, for the *combined residue* of BYI 02960 and DFA. The separated components are calculated to be 0.421 mg/kg feed of BYI 02960 and 0.980 mg/kg feed of DFA for chicken and 2.811 mg/kg feed of BYI 02960 and 1.479 mg/kg feed of DFA for cows. Using these dietary burden levels and and the transfer factors derived in the feeding studies (for the low-dose groups re. the total residue, and for the most relevant exposure scenarios), the notifier calculates that the following levels of total residues of BYI 02960 and DFA (expressed in parent compound equivalents) can be expected after feeding of realistic worst-case residues in feed crops to poultry, presented in table 7.12.1-3.

Table 7.12.1-3: Theoretical residues resulting from feeding BYI 02960 and DFA to poultry and to dairy cows in a ratio relevant to the actual residues expected in feed commodities

Dietary burden (mg/ kg feed)	Matrix	Transfer factor*	Resulting residue (mg/kg)
chicken			
BYI 02960			
0.421	egg	0.038	0.016
	muscle	0.062	0.026
	fat	0.026	0.11
	liver	0.076	0.032
DFA			
0.980	egg	0.097	0.095
	muscle	0.172	0.169
	fat	0.060	0.059

Dietary burden (mg/ kg feed)	Matrix	Transfer factor*	Resulting residue (mg/kg)
	liver	0.216	0.212
cattle			
BYI 02960			
2.811	milk	0.009	0.025
	muscle	0.013	0.037
	fat	0.009	0.025
	liver	0.036	0.101
	kidney	0.037	0.104
DFA			
1.479‡	milk	0.028	0.041
	muscle	0.094	0.139
	fat	0.068	0.101
	liver	0.091	0.135
	kidney	0.140	0.207

* for derivation of transfer factors, see 7.8.1
† when deriving factors, residue values of <LOQ were calculated as being at the LOQ, thus representing a worst case for exposure
‡ based on this dietary burden, the transfer factor chosen for DFA reflects the lowest dosed exposure rate, 1.5 mg/kg feed for poultry and 4.8 mg/kg feed for lactating ruminants

Table 7.12.1-4 summarizes the results of the theoretical residues calculated above by the notifier, matrix for matrix. The following levels of total residues of BYI 02960 and DFA (expressed in parent compound equivalents) can be expected after feeding of realistic worst-case residues in feed crops to poultry and dairy cows.

Table 7.12.1-4: Combined residues of BYI 02960 and DFA in poultry and bovine matrices as determined in the feeding study (1X)

Matrix	Residue levels* (mg/kg) based on feeding of			Proposed MRL

kidney	0.104	0.207	*0.311*	**0.40**

* all residue levels expressed in parent compound equivalents

B.7.12.2 Justification of proposed MRLs

Protected lettuce was presented to be the worst case with regard to residue levels (see table 7.6.2-1). For the MRLs proposed by the RMS, see tables 7.12.2-1 and 7.12.2-2. For plant products from ptrimary crops, the OECD MRL calculator was used. For MRLs based on succeeding crops, the HR was rounded up and this values is proposed a the MRL, in absence of guidance how to calculate

MRLs for rotational crops. ~~The proposed import tolerances are presented in the Evaluation Report on flupyradifurone, as it is considered that the imported products will in generally not be used for livestock feed.~~

MRLs for products of animal origin are based on the study reflecting the 1N dose rate, calculated with the dietary burden calculator according to SANCO guideline 7031/VI/95 and taking into account the results and the transfer factors derived from the livestock feeding studies. The results from the feeding study from the all 2N dose rates (dairy cow) were first normalised to 1N, the hen study was performed at 1N dose rate and was therefore not normalised. The theoretical exposure to DFA was included in the N-tae calcaulation, i.e 32.1% for poultry and 2.9% for cattle. This does however not take into account that livestock is exposed to mostly DFA in feed,and not to flupyradifurone.

DFA makes up 89-96% of the diet for chicken,dairy and beef cattle and pigs, whilst in the feeding studies, animals were exposed only to flupyradifurone. It is therefore expected that residues of DFA will be higher in practice.Therefore, the expert meeting concluded that feeding studie in poultry in cattle with DFA are required. The approach below is accepted in the meantime.

Table 7.12.2-2: Conversion of combined residues of BYI 02960 and DFA in poultry and bovine matrices as determined in the feeding studies to 1N dose level

The maximum estimated dietary burden of separate parent BYI 02960 and metabolite DFA residues in livestock commodities, based on EU crop residue data and the European dietary burden calculator, are presented for poultry and cattle below in table 7.12.2-4. To maintain a uniform approach, the commodities in their ratio from the total BYI 02960 residues in table 7.2-2 were used, even though the EFSA dietary burden calculator would selected other commodities in different ratios based on the input values of DFA and BYI 02960 separately.

Table 7.12.2-4: Theoretical residues resulting from feeding BYI 02960 and DFA to poultry and cattle in a ratio relevant to the actual residues expected in feed commodities

B.7.13 Proposed EU Import tolerances and justification for the acceptability of those residues

Flupyradifurone is to be registered worldwide and undergoing a Global Joint Review in the USA, Canada, Mexico, Brazil, and Australia.

~~Therefore, a~~ A large number of import tolerances have been applied for in the MRL application, parallel to the peer review of flupyradifurone. It was however decided during the peer review, not to consider these Its until they have een established as MRLs in the country of origin.

~~Crop~~	~~MRL proposal (mg/kg)~~	~~Commodity~~	~~MRL proposal (mg/kg)~~
~~Citrus fruits~~	~~3~~	~~Egg~~	~~0.5~~

B.7.14 Basis for differences, if any, in conclusions reached having regard to established or proposed CAC MRLs

Not applicable, because there are no established or proposed CAC MRLs.

B.7.15 Estimates of potential and actual dietary exposure through diet and other means (IIA 6.9; IIIA 8.8)

B.7.15.1 Intakes by domestic animals

The supported use on hops and lettuce are not relevant for intake by domestic animals. However, as flupyradifurone and its metabolites DFEAF and DFA occur in succeeding crops, exposure to livestock from the use of flupyradifurone on lettuce can occur.

Based on the metabolism studies in laying hen and lactating ruminants, a residue definition as the sum of flupyradifurone and metabolite DFA, expressed as flupyradifurone is proposed for risk assessment and for monitoring flupyradifurone and DFA, expressed as DFA, separately.

A livestock feeding study was performed in lactating cows and laying hens. As the animals were dosed only with the parent, whilst exposure to DFA can occur via feed, transfer factors were calculated to estimate the amount of DFA in products of animal origin in practice when livestock is also exposed to DFA. These transfer factors were not used for MRL proposal.

Based on the livestock feeding studies and estimated exposure, MRLs in animal products are proposed. See B.7.8.1 and B.7.12.2.

B.7.15.2 Intakes by humans (long-term)

Chronic exposure for the consumer was estimated using the input values in table 7.15.2-01~~, including the import tolerances~~ (see also Evaluation report on flupyradifurone), the ADI of 0.064 ~~0.08~~ ~~0.12~~ mg/kg bw/d and EFSAs PRIMo model rev.2. The IEDI ~~TMDI~~ uses maximally 15.1% ~~47.3~~ ~~75.6~~% of the ADI for the WHO Cluster diet B. All other European (national) diets use less of the ADI. The 5 highest outcomes are found in Table 7.15.2-02.

Table 7.15.2-01 Input values for the consumer risk assessment

Two ground water metabolites were identified, DFA and 6-~~CAN~~ CNA. The intake of these metabolites that can reach the ground water (and thus possibly occur in drinking water) was assumed to be insignificant as was discussed under B.6.9.6 (assessment of toxicological relevance of metabolites) and B.8.6.3.

The risk assessment has been performed on the basis of the MRLs collected from Member States in April 2006. For each pesticide/commodity the highest national MRL was identified (proposed temporary MRL = pTMRL).
The pTMRLs have been submitted to EFSA in September 2006.

Conclusion:
The estimated Theoretical Maximum Daily Intakes (TMDI), based on pTMRLs were below the ADI.
A long-term intake of residues of flupyradifurone is unlikely to present a public health concern.

Página 1

B.7.15.3 National estimate for short term intake by humans (acute)

Acute exposure for the consumer was estimated using the proposed MRLs in table 7.15.2-1~~, including the import tolerances~~ and the ARfD of 0.15 ~~0.35~~ mg/kg bw and EFSAs PRIMo model rev.2. The NESTI uses maximally 82.3 ~~69.2~~% of the ARfD for the German children for lettuce. All other commodities use less than 100% of the ARfD. Since the EU uses do not result in an exceeded ARfD, a refinement of the acute intake calculations was performed, using the HR values and processing factors where available. ~~but the import tolerances for celery and oranges do.~~

~~The refined IESTI calculations show that the ARfD is taken up for maximally 81.8% for lettuce.~~

Refining the acute intake calculations by using the HRs, results in a safe use.

Figure 7.15.3-1 Outcomes of acute consumer intake calculations using EFSA Primo rev 2

Acute risk assessment /children | **Acute risk assessment / adults / general population**

The acute risk assessment is based on the ARfD.

For each commodity the calculation is based on the highest reported MS consumption per kg bw and the corresponding unit weight from the MS with the critical consumption. If no data on the unit weight was available from that MS an average European unit weight was used for the IESTI calculation.

In the **IESTI 1** calculation, the variability factors were 10, 7 or 5 (according to JMPR manual 2002), for lettuce a variability factor of 5 was used.
In the **IESTI 2** calculations, the variability factors of 10 and 7 were replaced by 5. For lettuce the calculation was performed with a variabilty factor of 3.

Threshold MRL is the calculated residue level which would leads to an exposure equivalent to 100 % of the ARfD.

**) pTMRL: provisional temporary MRL
***) pTMRL: provisional temporary MRL for unprocessed commodity

Conclusion:

For flupyradifurone IESTI 1 and IESTI 2 were calculated for food commodities for which pTMRLs were submitted and for which consumption data are available.
No exceedance of the ARfD/ADI was identified for any unprocessed commodity.

For processed commodities, no exceedance of the ARfD/ADI was identified.

Page 1

B.7.16 Summary and evaluation of residue behaviour (IIA 6.10; IIIA 8.9)

Storage stability

Flupyradifurone, DFEAF, and DFA are stable in orange fruit (high acid content), spinach leaves and tomato fruit (high water content), wheat grain (high starch content), bean seed (high protein content), coffee bean (specific matrix), soybean seed (high oil content), and sugar cane (high water content) for at least 18 months when stored frozen.

DFA is stable in animal fat, kidney, liver, and muscle for at least 43 days, when stored frozen.

In the confined rotational crop studies, stability of flupyradifurone residues was additionally demonstrated for 18-24 months at ≤ -18 °C for Swiss chard and wheat straw.

Primary metabolism in crops

The metabolism of flupyradifurone (BYI 02960) was investigated in five target crops (tomato, potato, apple, cotton and rice) following application of [furanone-4-^{14}C] flupyradifurone and [pyridinylmethyl-^{14}C] flupyradifurone. Additionally, [ethyl-1-^{14}C] flupyradifurone was applied in one tomato metabolism study. In all other plant metabolism studies, the fate of the difluoroethane moiety of the active substance was tracked by analysing extracts of all RACs for non-radiolabelled difluoroacetic acid, the most plausible metabolite which can be formed from the moiety after cleavage of the parent compound. The analysis of difluoroacetic acid was initiated after detecting difluoroacetic acid as a major soil metabolite in the aerobic soil degradation studies.

The active substance was applied either as an SL formulation for drench and foliar application, an FS formulation for seed/tuber treatment or as a granule to cover the special application technique in rice in Japan.

The metabolism studies conducted in these five crops represent four different crop groups (fruiting crops, root and tuber vegetables, pulses and oilseeds and cereals) showed similar profiles, with the unchanged parent compound and metabolite difluoroacetic acid representing the major part of the residue.

The metabolism in all plants was very similar. The main reactions involved were:

- Oxidative cleavage of the difluoroethylamine bond and formation of difluoroacetic acid,
- complete degradation of the furanone moiety and incorporation of carbon atoms into the natural compound pool, e.g. into glucose/carbohydrates,
- cleavage of the pyridinylmethylamine bond and formation of BYI 02960-difluoroethylamino-furanone and BYI 02960-CHMP / BYI 02960-6-CNA,

- formation of BYI 02960-CHMP was followed by conjugation with carbohydrates and sulphate or by oxidation of the methylene group to a carboxylic group and subsequent conjugation with glycerol and glucuronic acid,
- hydroxylation of the furanone or the difluoroethyl moiety followed by conjugation with carbohydrates and sulphate, and
- oxidative degradation of the furanone moiety to an acetic acid group followed either by conjugation with a carbohydrate or by further oxidation or degradation of the moiety.
- Halogenation (bromination/chlorination) of the furanone moiety of the parent compound was most probably a process which took place in the soil.

Thus, oxidative cleavage of the molecule, oxidation and hydroxylation were the primary transformation steps followed by conjugation reactions with glycosides, sulphate and glucuronic acid.

Generally, these main metabolic reactions were also observed in the rat studies on absorption, distribution, metabolism and elimination (ADME). Parent compound and all major plant metabolites, or at least subsequent metabolites which imply the presence of the plant metabolites as transient metabolites were detected, although flupyradifurone shows a more moderate degradation behaviour in rats compared to plants.

Metabolism in rotational crops

The metabolism of flupyradifurone (BYI 02960) residues in the rotational crops wheat (small grain), Swiss chard (leafy crop) and turnip (root crop) was investigated at a nominal application rate of 400 g a.s./ha. The plant back intervals were 29, 135 and 296 days for all crops. The studies were conducted with [furanone-4-^{14}C]BYI 02960 and [pyridinylmethyl-^{14}C]BYI 02960. A study with [ethyl-1-^{14}C]BYI 02960 was not conducted and therefore non-radiolabelled difluoroacetic acid was determined in all extracts obtained in the CRC study conducted with [furanone-4-^{14}C]BYI 02960 to gain information on the fate of the difluoroethane moiety of the active substance.

Corresponding TRR values showed similar residue levels when comparing the studies performed with [furanone-4-^{14}C]BYI 02960 and [pyridinylmethyl-^{14}C]BYI 02960. Generally, the TRR values were slightly higher in the crops of 1st and 2nd rotation of the study performed with [pyridinylmethyl-^{14}C]BYI 02960, except for wheat grains, where it was the opposite way round due to the selective transport of glucose as a label specific metabolite into the RAC.

The levels of parent compound decreased with increasing plant back intervals but nevertheless parent formed a main portion of the residues in all of the RACs in all rotations, except for wheat grains. Other major metabolites (accounting for >10% of the TRR in at least one RAC in one rotation) were

- DFA, which was the main metabolite in wheat grains (all rotations) and in turnip roots (1st rotation) and a major metabolite in all other RACs

- 6-CNA-glucerol-gluA (3 isomers), which were major in and specific for all wheat commodities and accounted in sum for 11% to 33% of the TRR considering all rotations
- BYI 02960-difluoroethyl-amino-furanone, which was a major metabolite in all Swiss chard samples in all rotations and accounted for up to 17% of the TRR
- BYI 02960-OH-glyc, which was major in Swiss chard and turnip leaves in all rotations
- BYI 02960-glyoxylic acid, which was only a major metabolite in wheat forage, hay and straw and in turnip roots of the first rotation, in subsequent rotations it was detected in minor amounts, only
- BYI 02960-bromo-amino-furanone, which was only major in wheat hay of the 3rd rotation
- BYI 02960-OH, which was major in wheat grains of the 1st rotation, only
- Glucose/carbohydrates, which were identified as the main portion in wheat grains after exhaustive extraction and as a major metabolite in turnip roots after conventional extraction.

The proposed metabolic pathway is very similar to the one of primary crops. As observed in target plants the metabolic reactions involved were hydroxylation and oxidative cleavage of the active substance followed by additional oxidation and conjugation processes. No additional metabolic routes were detected, only additional metabolites were identified, e.g. additional conjugates or existing metabolites were subjected to further oxidation reactions.

Metabolism in livestock

The metabolism of flupyradifurone (BYI 02960) was investigated in laying hens and lactating goats following oral administration of [pyridinylmethyl-^{14}C] flupyradifurone and [furanone-4-^{14}C] flupyradifurone for both species.

The concentrations of the identified metabolites in the different matrices are basically in the same order of magnitude independent of the label employed. However, after administration of the furanone-labelled test compound, the concentrations of the total radioactivity in eggs and edible tissues of laying hens as well as in milk and fat of lactating goats are higher. This is attributable to the fact that the radioactivity originating from this label is incorporated into natural compounds like fatty acids in all poultry tissues and lactose in the milk of goats.

Notwithstanding these observations, the unchanged parent compound is a significant, if not the dominating constituent of the residue in milk, eggs and edible tissues of both species. Other metabolites determined in comparable concentrations are the natural compound lactose in the milk of goats after administration of [furanone-4-^{14}C]BYI 02960, and BYI 02960-acetyl-AMPC in eggs and tissues of poultry after administration of [pyridinylmethyl-^{14}C] BYI 02960.

The main metabolic reactions involved were:

- Hydroxylation in position 5 of the furanone ring forming BYI 02960-hydroxy followed by conjugation with sulfuric acid to BYI 02960-OH-SA
- Hydroxylation followed by conjugation with glucuronic acid forming two diastereomeric conjugates of BYI 02960-OH (BYI 02960-OH-gluA, isomer 2 and 3), the hydroxylation and conjugation being in the 5-position of the furanone ring. One isomer (BYI 02960-OH-gluA, isomer 4) with hydroxylation and conjugation in the difluoroethyl side chain and one isomer (BYI 02960-OH-gluA, isomer 1) with hydroxylation and conjugation in an unknown position
- Oxidative cleavage of the pyridinylmethyl moiety forming BYI 02960-6-CNA as well as subsequent total degradation of the furanone ring forming smaller carbon units (C-1- or C-2-fragments), entering the carbon pool of endogenous compounds and then being used either for the biosynthesis of fatty acids of lactose
- Substitution of the chloro group of BYI 02960-6-CNA with glutathione followed by degradation resulting in the conjugates BYI 02960-acetyl-cysteinyl-nicotinic acid and BYI 02960-lactato-mercaptyl-nicotinic acid
- Cleavage of the difluoroethyl group forming BYI 02960-des-difluoroethyl followed by hydroxylation and conjugation with sulfuric acid to BYI 02960-des-difluoroethyl-OH-SA
- Cleavage of the furanone ring and conjugation with sulfonic acid forming BYI 02960-AMCP-difluoroethanamine-SA
- Cleavage of the furanone ring and the difluoroethyl group forming an amine followed by acetylation to BYI 02960-acetyl-AMCP and BYI 02960-AMCP-difluoroethanamine
- Cleavage of the difluoroethyl group forming BYI 02960-des-difluoroethyl and difluoroacetic acid

These main metabolic reactions were also observed in the rat studies on absorption, distribution, metabolism and elimination (ADME) of BYI 02960 (see B.6 ~~refer to KIIA 5.1~~) and therefore the toxicological coverage of the livestock metabolites is given. Parent compound and all major plant metabolites, or at least subsequent metabolites which imply the presence of the livestock metabolites as transient metabolites were detected.

Difluoroacetic acid was determined in selected livestock samples by high resolution LC-MS subsequently to the metabolism studies since rat studies conducted with [ethyl-1-14C]BYI 02960 showed major amounts of this metabolite in organs and tissues. Extrapolation of rat data suggested high difluoroacetic acid levels in livestock tissues as well which was confirmed by the non-radioactive LC-MS analyses. Based on these findings, it was concluded that difluoroacetic acid is a major livestock metabolite and should be - besides parent compound - part of the residue definition for data collection, risk assessment and enforcement.

Definition of the Residue

Plants

Residue definition for monitoring:

Results from supervised residue trials show that flupyradifurone and difluoroacitic acid (DFA) are, by far, the most prominent components of the residues in target plants and rotational crops. The residues of metabolite BYI 02960-difluoroethyl-amino-furanone (DFEAF) were below the LOQ of 0.01 mg/kg in virtually all samples. Considering these results as well as those from the metabolism studies, the proposed residue definition for monitoring for target plants and rotational crops is:

~~**The sum of parent compound and DFA, expressed in flupyradifurone equivalents.**~~

1) flupyradifurone

2) DFA, expressed as DFA

Separatly

Residue definition risk assessment:

For flupyradifurone residues in target plants (primary crops) and rotational crops (succeeding crops), the proposed residue definition for data collection and risk assessment is:

The sum of parent compound flupyradifurone and its metabolites DFA ~~and BYI 02960-difluoroethyl-amino-furanone (DFEAF~~), expressed in flupyradifurone equivalents. ~~A conversion factor is not required to cover the difference between the residue definition for monitoring and risk assessment as both DFA and flupyradifurone are part of the residue definition for monitoring and as DFEAF is found in levels below <0.01 mg/kg in supervised residue trials and in rotational crops.~~

Animals

Residue definition for monitoring:

~~**The sum of parent compound and DFA, expressed in flupyradifurone equivalents.**~~

1) flupyradifurone

2) DFA, expressed as DFA

Separatly

Residue definition risk assessment:

The sum of Flupyradifurone and metabolite DFA, expressed in flupyradifurone equivalents.

Supervised residue trials

Protected Lettuce

Nine acceptable residue trials performed in accordance with the cGAP for greenhouse use have been provided.

In the greenhouse trials a highest residue value (HR) of 6.04 mg/kg was determined and an the STMR of 2.12 mg/kg for the sum of flupyradifurone and DFA, expressed as flupyradifurone.

Unprotected Lettuce

For the envisaged outdoor use in Northern and Southern Europe with a 10d PHI the required number of trials are available (nine acceptable trials for each region).
For the envisaged agricultural outdoor use in Northern and Southern Europe with a 3d PHI, the residue trials performed with lettuce in Northern and Southern Europe are not acceptable, except for two trials with sampling 2 days after the 1st treatment. No samples were taken 3 days after the first application. However, the results from the trials performed with outdoor lettuce in Northern and Southern Europe at 3 days after the 2nd treatment were valid to determine that the intended use on protected lettuce can be identified as the worst case residue situation, based on a comparison of the residue values from field and greenhouse testing using the most critical use pattern (2x125 g as/ha, int. 10d, PHI 3d).
Moreover, the tested GAP with two applications and a pre-harvest interval of 3 days is the "home and garden" use, which was submitted in parallel and is envisaged for registration shortly after the agricultural use (see the Evaluation Report for Flupyradifurone as an appendix to Vol. 3, B7). Since this field use is more critical than the agricultural field use, it was agreed with the RMS to conduct all field residue trials according to this GAP to identify the most critical consumer exposure and to avoid re-evaluation of MRLs due to this use. Hence, the trials in the DAR are not in accordance with the cGAP in the DAR, but with the cGAP supported in EU for MRL setting.

Thus, the open field trials in lettuce in Northern and Southern Europe are in compliance with the envisaged "home and garden"use. In addition, sufficient trials were performed providing evidence that the envisaged greenhouse can be identified as the worst case residue situation. Therefore no further trials are required.

Hops

In hops, eight valid trials were conducted in the northern European residue region in the years 2010-2011. Flupyradifurone was applied once as an SL 200 formulation at an active substance rate of 120 - 150 g/ha. All applications were at acceptable rates, and all trials were conducted according to GLP. in dried cones, residue levels also tended to decline with time. When evaluating the highest residues at relevant sampling intervals (either day 21 or, in three trials, day 28), residues ranged from 0.34-2.3 ~~0.61-2.4~~ mg/kg, with a median of 1.05 ~~1.15~~ mg/kg for the sum of flupyradifurone and DFA, expressed as flupyradifurone.

Processing studies

Nature of residues

Flupyradifurone stable under all conditions of high temperature hydrolysis for simulation of food processing. The following conditions were tested:

- pH 4 / 90°C (20 min) - pasteurisation
- pH 5 / 100°C (60 min) - baking, brewing, and boiling

- pH 6 / 120°C (20 min) - sterilisation

Metabolite DFEAF is a substructure of the parent compound. All functional groups, chemical moieties and their constitution of DFEAF are also present in the chemical structure of the parent compound. Therefore the chemical stability DFEAF is covered by studies with the parent compound. As parent compound was proved to be stable under the processing conditions, it is concluded that this is also true for DFEAF. In addition, in almost all uses worldwide – and certainly in all EU-relevant uses – DFEAF does not play any significant role in the field residues, generally comprising <5% of the total residue.

Due to the similarity of the chemical structures, the properties of DFA (= difluoroacetic acid) can be interpolated from the properties of TFA (= trifluoroacetic acid) and HOAc (acetic acid). The latter compounds are very common in organic chemistry, have often been used in chemical synthesis and many properties have been investigated. It can be deduced from literature data that these two compounds are stable under the conditions to be tested in a processing study. By interpolation of these properties, it is concluded that DFA is also stable under the processing conditions.

Magnitude of Residues

Household preparation of lettuce heads, i.e. removing outer leaves and washing the remaning head (separated in inner and outer head) resulted in processing factors of 1.8 for outer leaves, 0.72 ~~0.73~~ for inner head parts and 0.87 ~~0.76~~ for inner leaves.

Using hops in the production of beer, the transfer factors was determined to be 0.01. In the intermediates in the production of beer, the average processing factor was <0.1.

Field rotational crop studies

Four multi-plantback multi-crop rotational crop trials were conducted in Europe (2 each in the northern and southern residue regions) in the years 2010-2011. Flupyradifurone was applied once as an SL 200 formulation either to bare soil or to a target crop (lettuce) at an active substance rate of 200 g/ha, the target crop was then harvested, and crops representing 3 different botanical groups (roots, leafy veg., cereals) were planted on the plots at 3 intervals thereafter. All applications were at the required rates, and all trials were conducted according to GLP.

Quantifiable residues were measured in all rotations. Total residues of BYI 02960 in all rotational crops tended to be highest in the first, earliest rotation with a plant back interval of 25-33d.

Residues ranged from 0.05-0.14 mg/kg (median 0.06 mg/kg) in early harvest root crops, from 0.06-0.21 mg/kg (median 0.08 mg/kg) in early harvest leaf crops, 0.05-0.41 mg/kg (median 0.10 mg/kg) in cereal green forage, <0.07-0.39 mg/kg (median 0.12 mg/kg) in barley straw and from 0.11-0.65 mg/kg (median 0.35 mg/kg) in cereal grain grown in the first rotation, residues as the sum of flupyradifurone and DFA, expressed as flupyradifurone.

Up to the third rotation, residues above the LOQ were detected.

Additionally, field rotational crop trials were performed representative for each type of crop at short plant back intervals (PBI 30 days) and in accordance with the supported maximum dose rate of 2 × 125 g a.s./ha. Potatoes, leek, cucumber, onion, bean (fresh), peas (dry) and winter rape were grown at 2 locations in Northern and at 2 locations in Southern Europe. BYI 02960 and DFEAF residues were always <0.01 mg/kg while soil metabolite DFA was present in all trials except for one onion trial. Residues at harvest showed considerable variation which could not be attributed to geographical zone, soil type, pH, organic matter content, and temperature during treatment, rainfall after treatment or growth period (results not shown). Therefore, results for Northern and Southern Europe are considered as one data set with considerable variation.

HRs of DFA, expressed as DFA were 0.083, 0.076, 0.136, 0.053, 0.365, 0.764 and 0.050 ~~0.27, 0.25, 0.43, 0.18, 1.1, 2.3 and 0.17~~ mg/kg in potatoes, leek, cucumber, onion, bean, peas and winter rape, respectively.

Livestock Feeding studies

Flupyradifurone was administered orally to laying hens for 29 consecutive days at average dose rates of 1.5 mg/kg feed (1.2N) 6.5 mg/kg feed (5.4N ~~4.3N~~ ~~4.9N~~), 19.4 mg/kg feed (16N ~~13N~~ ~~14.7N~~), and 65.1 mg/kg feed (54N ~~43N~~ ~~49N~~). After the final dose, the animals were sacrificed and the key edible tissues were analyzed for the relevant residues of flupyradifurone. The combined residues of flupyradifurone + DFA in poultry tissues at sacrifice in the 1.2N dosing group were 0.093 mg/kg in muscle, 0.039 mg/kg in fat, and 0.11 mg/kg in liver, expressed in parent compound equivalents. Prior to sacrifice, residues in eggs were measured at various intervals in the high-dose group, and on days 24 and 28 in the three lower dose groups. In the 1N dose group, residues (flupyradifurone + DFA) in eggs amounted to 0.061 and 0.057 mg/kg, respectively.

Residue analysis of the high-dose eggs showed that levels reached a plateau in eggs. Though residues were highest at day 28, residue data from the 54N ~~43N~~ ~~49N~~ egg samples, when evaluated against the dose rate increases calculated as mg a.s./kg bw, suggest that flupyradifurone residues actually reached a plateau between day 4 and day 7; increases in residue levels were only due to increased dose rates.

Depuration occurred quickly. Total flupyradifurone residues in eggs, fat, liver, and muscle from the 54N ~~43N~~ ~~49N~~ dose level hens declined from 1.722, 1.230, 3.480, and 2.410 mg/kg, respectively, to <LOQ at 14 days after cessation of dose administration (=day 42 of the study).

DFA residues represented 65% to 74% of the total flupyradifurone residues in the excreta samples, suggesting significant exposure of the laying hens to DFA residues following the administration of BYI 02960 for 29 days.

Flupyradifurone was administered orally to dairy cows for 29 consecutive days at average *actual* dose rates of 4.8 mg/kg feed (1.6N ~~1.8N~~ ~~2N~~ dose), 23 mg/kg feed (8N ~~9N~~ ~~8N~~), 50 mg/kg feed (17N ~~19N~~ ~~18N~~), and 135 mg/kg feed (44N ~~52N~~ ~~49N~~).

After the final dose, the animals were sacrificed and the key edible tissues were analyzed for the relevant residues of BYI 02960.

The combined residues of BYI 02960 + DFA in bovine tissues at sacrifice in the 1.6N ~~1.8N~~ ~~2N~~ dosing group were 0.063 mg/kg in muscle, 0.041 mg/kg in fat, 0.18 mg/kg in kidney, and 0.17 mg/kg in liver, expressed in parent compound equivalents. Prior to sacrifice, residues in milk were measured at various intervals in the high-dose group, and on day 28 in the three lower dose groups. In the 1.6N ~~1.8N~~ ~~2N~~ dose group, the residues (BYI 02960 + DFA) amounted to 0.043 mg/kg.

Residue levels reached a plateau in milk. Highest residue were determined at day 17 in the 44N ~~52N~~ ~~49N~~ milk samples, remaining at similar levels for the remainder of the study.

Depuration occurred quickly. Total BYI 02960 residues in milk, fat, liver, kidney, and muscle from the 44N ~~52N~~ ~~49N~~ dose level cows declined from 0.81, 1.40, 1.59, 5.39, and 1.91 mg/kg, respectively, to <LOQ at 6-7 days after cessation of dose administration (=day 35-36 of the study).

Livestock will be exposed to DFA and flupyradifurone through feed as these are the major residues in plants. Based on the data from the feeding studies in which only parent flupyradifurone was dosed, transfer factors were proposed to estimate consumer exposure and to calculate MRLs for the sum of DFA and flupyradifurone. The feeding studies were designed to allow "material balancing" in order to evaluate levels and calculate transfer factors for both the total residue (parent BYI 02960 and DFA) and DFA, despite feeding parent compound only. Since this not an accepted approach, it was concluded in the expert meeting thatfeeding studies with DFA are required. In the meantime, the available study will be used for provisional MRL setting.

Consumer risk assessment

Based on the supervised residue trials, the field rotational crop trials, the livestock feeding studies and the calculated livestock transfer factors, MRLs are proposed:

Crop	MRL proposal (mg/kg)	
	Flupyradifurone	**DFA, expressed as DFA**
Lettuce	9	0.1
Hops	4	0.4
Rotational root and tuber vegetables	0.01	0.09
Rotational stem vegetables	0.01	0.08
Rotational bulb vegetables	0.01	0.06
Rotational fruiting vegetables	0.01	0.15
Rotational legume vegetables	0.01	0.4
Rotational leafy vegetables	0.08	0.04
Rotational cereals and sweet corn	0.01	0.3

Rotational pulses	0.01	0.8
Rotational oilseeds	0.01	0.05
eggs	0.01*	0.03
poultry meat (muscle)	0.01*	0.05
poultry fat	0.01*	0.03
poultry liver/offal	0.01*	0.1
milk	0.01*	0.03
Ruminant, pig and horse meat (muscle)	0.01*	0.1
Ruminant, pig and horse fat	0.01*	0.1
Ruminant, pig and horse liver	0.01*	0.1
Ruminant, pig and horse kidney	0.01*	0.15
other ruminant, horse and pig offal	0.01*	0.15

~~Lettuce 9 mg/kg~~

~~Hops 5 mg/kg~~

~~Rotational root vegetables 0.6 mg/kg~~

~~Rotational tuber vegetables 0.6 mg/kg~~

~~Rotational stem vegetables 0.5 mg/kg~~

~~Rotational bulb vegetables 0.4 mg/kg~~

~~Rotational fruiting vegetables 0.9 mg/kg~~

~~Rotational legume vegetables 2 mg/kg~~

~~Rotational leafy vegetables 0.4 mg/kg~~

~~Rotational cereals and sweet corn 1.5 mg/kg~~

~~Rotational pulses 5 mg/kg~~

~~Rotational oilseeds 0.3~~ ~~0.4~~ mg/kg

~~eggs 0.15 mg/kg~~

~~poultry meat (muscle) 0.20 mg/kg~~

~~poultry fat 0.09~~ ~~0.07~~ mg/kg

~~poultry liver/offal 0.30 mg/kg~~

~~milk 0.06~~ ~~0.08~~ mg/kg

~~Ruminant and horse meat (muscle) 0.20~~ ~~0.30~~ mg/kg

~~Ruminant and horse fat 0.20~~ ~~0.30~~ mg/kg

~~Ruminant and horse liver 0.20~~ ~~0.30~~ mg/kg

~~Ruminant and horse kidney 0.30~~ ~~0.40~~ mg/kg

~~other ruminant, horse and pig offal 0.30~~ ~~0.40~~ mg/kg

~~Pig meat (muscle) 0.40~~ ~~0.30~~ mg/kg

~~Pig fat 0.40~~ ~~0.20~~ mg/kg

~~Pig liver 0.40~~ ~~0.30~~ mg/kg

~~Pig kidney 0.60~~ ~~0.30~~ mg/kg

~~Other pig offal 0.60 0.30~~ mg/kg

~~Using these MRLs, and import tolerances applied for, dietary exposure assessments were performed.~~
Chronic and acute exposure for the consumer was estimated using the proposed MRLs, the ADI of 0.064 ~~0.08 0.12~~ mg/kg bw/d, the ARfD of 0.15 ~~0.35~~ mg/kg bw and EFSAs PRIMo model rev.2. The IEDI ~~TMDI~~ uses maximally 15.1% ~~47.3 75.6~~% of the ADI for the WHO Cluster diet B. All other European (national) diets use less of the ADI.
The NESTI uses maximally 82.3 ~~69.2~~% ~~of the ARfD UK infants for oranges (import tolerance) and 69.2%~~ of the ARfD for German children for lettuce after refinement with the HR-P. All other commodities use less of the ARfD in other consumer diets.

B.7.17 References relied on

A literature search and review was provided by the applicant. The search has been conducted in line with the EFSA guidance. Of all identified papers (342) the relevant ones (136) have been selected by the applicant in a transparent way using a text mining filter. The applicant provided a general justification for evaluating the relevant papers. As no study-by-study justifications were given, the RMS cannot properly verify whether the 136 relevant papers were correctly evaluated in terms of reliability/validity/acceptability for regulatory use. The one study that was considered relevant by the applicant is evaluated in the DAR. RMS notes that flupyradifurone is a new active substance worldwide. Therefore, public literature is not expected to be an important new information source for the active substance itself.

Annex I

List of Metabolites

In the original study reports on BYI 02960 the metabolites are sometimes named by different synonyms. In order to present a common basis for the evaluation of the active substance and its degradation products a complete list of metabolites is presented.

The following abbreviations were used:

gluc = glucoside (conjugation with glucose)
glyc = glycoside (conjugation with a hexose)
gluA = glucuronide (conjugation with glucuronic acid)
OH = hydroxy
SA = sulfate

	Report name, Structure **IUPAC name** **CAS name, [CAS number]**	**Molecular formula** **molar mass** **Other names / codes**	**Occurrence**

B.8 Fate and behaviour

Rapporteur Member State: The Netherlands

January 2014 November 2014 December 2014

Draft Assessment Report and Proposed Decision of the Netherlands prepared in the context of the possible inclusion of flupyradifurone in Annex I of Council Directive 1107/2009/EEC

Contents

B.8	Environmental fate and behaviour	1
B.8.1	Route and rate of degradation in soil (Annex IIA 7.1.1; Annex IIIA 9.1.1)	3
B.8.2	Adsorption, desorption and mobility in soil (Annex IIA 7.1.2 and 7.1.3; Annex IIIA 9.1.2)	140
B.8.3	Predicted environmental concentrations in soil (PECS) (Annex IIIA 9.1.3)	196
B.8.4	Fate and behaviour in water (Annex IIA 7.2.1; Annex IIIA 9.2.1, 9.2.3)	174
B.8.5	Impact on water treatment procedures (Annex IIIA 9.2.2)	244
B.8.6	Predicted environmental concentrations in surface water and in ground water (PECsw, PECgw) (Annex IIIA 9.2.1, 9.2.3)	245
B.8.7	Fate and behaviour in air (Annex IIA 7.2.2; Annex IIIA 9.3)	276
B.8.8	Predicted environmental concentrations in air (PECa) (Annex IIIA 9.3)	280
B.8.9	Definition of the residue (Annex IIA 7.3)	281
B.8.10	References relied on	282

B.8 Environmental Fate and Behaviour

Information is provided in this chapter with respect to the fate and the behavior in soil, water and air of flupyradifurone (BYI 02960). This active substance is an insecticide which is active against various pests such as aphids, white flies and hoppers in many target crops such as fruits, vegetables, plantations, cereals and soybean.

Internal code:	BYI 02960
CAS-No.:	951659-40-8
Chemical name:	4-[(6-chloro-3-pyridylmethyl)(2,2-difluoroethyl)amino]furan-2(5H)-one
Molecular mass:	288.68 g/mol (non-labelled)
Molecular formula:	$C_{12}H_{10}ClF_2N_2O_2$

The studies concerning the fate and behavior of BYI 02960 in the environment were conducted using different radiolabelled forms, [pyrindinyl-methyl-^{14}C], [pyridine-2,6-^{14}C], [furanone-4-^{14}C] and [ethyl-1-^{14}C] BYI 02960 as well as the non-labeled parent compound. These label positions are sufficient to define the degradation pathway. In the Tier II summaries that follow, the different radiolabels are referred to as PYM (= pyrindinyl-methyl-^{14}C-label), PYR (= pyridine-2,6-^{14}C-label), FUR (= furanone-4-^{14}C-label) and ETH (= ethyl-1-^{14}C-label). The structure of BYI 02960 and the positions of the different radiolabels are as follows:

[Pyridinyl-methyl-^{14}C]
BYI 02960
(PYM-^{14}C)

[Pyridine-2,6-^{14}C]
BYI 02960
(PYR-^{14}C)

[Furanone-4-^{14}C]
BYI 02960
(FUR-^{14}C)

[Ethyl-1-^{14}C]
BYI 02960
(ETH-^{14}C)

* indicates position of radiolabel

In addition, studies were performed with the following metabolites (radiolabelled or non-radiolabelled):

Difluoroacetic acid
(DFA)

6-Chloronicotinic acid
(CNA)

In original reports study authors may have used different names or codes for degradation products of BYI 02960. In this summary, a single name and a single code number is used for each metabolite, details are given at the end of the section.

List of concordances for names and designations of compounds

STUDY IIA, 7.1.1/01

Characteristics

Reference	:	Menke, U., 2011	study type	:	aerobic soil degradation
year of execution	:	2007-2009	incubation time	:	120 days
GLP statement	:	yes	nominal concentration	:	0.53 mg / kg soil
Guideline	:	OECD 307 (2002) US EPA, OPPTS 835.4100 (2008) OECD106 (2001)	temperature	:	20°C
test substance	:	[pyridinyl-methyl-^{14}C] BYI 02960	DT50	:	see results
Purity	:	> 99%	metabolites	:	see results
Soils	:	four soils; sandy loam, silt loam, loam, clay loam	acceptability	:	**acceptable**

Summary

The biotransformation and time dependent sorption of [pyridinylmethyl-^{14}C] BYI 02960 was studied in four European soils: Laacher Hof AXXa (AX), Höfchen am Hohenseh (HF), Hanscheiderhof Plot 611 (HN), and Dollendorf II (DD) for a maximum period of 120 days under aerobic conditions in the dark at approx. 20°C and 55% WHC_{max} (max. water holding capacity). BYI 02960 was applied at the nominal rate of 0.53 mg/kg soil, which is equivalent to 200 g/ha field application rate.

At each sampling date the soil samples were shaken for 24 hours with 400 mL $CaCl_2$-solution in order to measure the time-dependent desorption of the test item. Subsequently they were extracted by shaking at ambient temperature and in a microwave at 70 °C with acetonitrile/water mixtures, and the BYI 02960 residues were analyzed and quantified by TLC with HPLC as the confirmatory method.

Material balances were complete throughout the study, and the test item declined from 97.1, 96.1, 96.5 and 93.1% AR at DAT-0 to 37.1, 24.5, 50.2 and 28.7% in soils AX, HF, HN and DD, respectively, at the end of the study. Applying double first-order kinetics a half-life (geometric mean) of 68.8 days was calculated for BYI 02960 in the tested soils under aerobic conditions.

The mineralization of [PYM-^{14}C] BYI 02960 in this study was high. At the end of the study (DAT-120) up to 45.3 (AX), 58.6 (HF), 29.4 (HN) and 57.3% AR (DD) of $^{14}CO_2$ were generated. Volatile organic compounds were negligible (≤ 0.1% AR). With the exception of carbon dioxide only very minor transformation products (all were below 3% AR) were detected. Non-extractable ^{14}C-residues (NER) increased from 1.0, 1.5, 1.9 and 4.1% AR at DAT-0 to 12.6, 13.2, 16.8 and 12.5% AR at the end of the study period.

The part of the study related to time dependent sorption of [PYM-^{14}C] BYI 02960 is summarized in the mobility chapter (see B.8.2).

Materials and methods

Materials

1. Test Item: Flupyradifurone: Code = BYI 02960; Label PYM = [Pyridinyl-methyl-^{14}C] BYI 02960 (sample ID: BECH 2123); Specific activity 4.37 MBq/mg; Radiochemical purity: >99% (acc. radio-HPLC and -TLC); Chemical purity: >99% (HPLC, UV detection at 210 nm); Identity and purity of test item in the application solution were confirmed.

2. Soil: The biotransformation of [PYM-^{14}C] BYI 2960 was studied in four different soils (Table B.8.1.1.1-01). These soils are representative for agricultural use areas as required by the guidelines and cover a representative range of physico-chemical properties. All soils were taken fresh from the fields. Two days later, i.e. four days before starting the test the air dried soils were sieved through a 2 mm sieve. Three days before application aliquots equivalent to 100 g dry matter were weighed into individual 300 mL Erlenmeyer flasks and fitted with trap attachments. The soils were pre-equilibrated at 20 °C in the dark.

Methods

1. Experimental conditions: The study was performed in static incubation test systems under aerobic conditions in the dark at 19.8 ± 0.26 °C. The test system consisted of Erlenmeyer flasks (300 mL)

attached with a trap attachment (permeable to oxygen) containing soda lime for absorption of $^{14}CO_2$ and a polyurethane foam plug for adsorption of volatile organic compounds. Aliquots of 100 g of dry soil were weighed into the test flasks (each 21 flasks/soil). For all soils replicates were set up for each sampling (9 sampling dates including time 0). Three flasks for each soil were used for determination of the microbial biomass. The final soil moisture was adjusted to 55% of WHCmax by adding pure water.

2. Test Item Stock Solution: The entire amount of [PYM-^{14}C] BYI 02960 delivered was dissolved in 5 mL acetonitrile / water 1:1 (v/v).

3. Test Item Application Solution: An application solution (total volume 120 mL) was made by diluting 2082 µL of the stock solution with 117.92 mL of distilled water.

4. Mode of Application: aliquots of 991 µL of the application solution were applied in droplets onto each of the 100 g pre-incubated sub-samples from each soil. BYI 02960 was applied to the test soils at a treatment rate of 50.22 µg (219.442 kBq) per vessel. This value is equivalent to 94% of the nominal value of the application rate of 53.33 µg per vessel (calculated for a single application of 200 g BYI 02960 per hectare).

5. Sampling: Microbial biomass was determined prior to commencement of the test (soils sampled at the day of application), after 59 days, and at the end of the study 120 Days After Treatment (DAT-120). Entire test flasks were taken for processing and analysis at DAT-0, DAT-1, DAT-3, DAT-7, DAT-14, DAT-21, DAT-30, DAT-59, and DAT-120.

Prior to opening the incubation flasks (for moistening or sampling of soil), volatile (radioactive) compounds, possibly still present in the flasks, were transferred into the trap attachment by subjecting the flasks to vacuum in an excicator. At each sampling date the entire amount of soil in each test vessel was transferred into a centrifuge beaker and extracted using a mechanical shaker.

6. Description of analytical procedures: The soil processing procedure was optimized to obtain >90% extraction efficiency and >90% recovery of the test item at time zero. First, the test soils were shaken for 24 hours with 400 mL $CaCl_2$-solution to measure the time-dependent desorption of the test item. Subsequently they were extracted 4 times by shaking at ambient temperature and once in a microwave at 70 °C with acetonitrile/water mixtures, the [PYM-^{14}C] BYI 02960 residues were analyzed and quantified by LSC and normal phase Si-60 TLC with HPLC as the confirmatory method. Solid samples (i.e. soil and paper filters) were combusted and ^{14}C levels were measured using LSC. The identity of individual residues was established initially by spectroscopic methods. Within the course of the study compound identities were confirmed by co-chromatography using non-labeled reference substances.

Results

Results indicated that anticipated standardized conditions were maintained, and the soils were microbial active over the duration of the laboratory study (see Table B.8.1.1.1-01).

Data

The respective data for the four soils are shown in Table B.8.1.1.1-02 to Table B.8.1.1.1-05. The DAT-0 extraction efficiency of total radioactivity was 94.4 to 97.8% applied radioactivity (AR; mean 96.6% AR; sum of extracts only). The stability of the test item was verified by DAT 0 values of 93.1 to 97.1% AR for the soil extracts (mean 95.2% AR). These results indicated that the extraction method was appropriate for extraction of the applied [^{14}C]-labeled test item from the soil matrix.

Mass balance

The material balances were 96.1 to 99.2% (soil AX), 96.1 to 101.1% (soil HF), 95.6 to 102.4% (soil HN), and 97.1 to 101.3% (soil DD) of the applied radioactivity (% AR; mean values). There was no decrease over the incubation time.

Extractable and Bound Residues (NER)

Extractable ^{14}C-residues decreased from 97.8, 97.0, 97.2, and 94.4% AR at DAT-0 to 41.3, 29.3, 53.4 and 31.5% AR at study end (DAT-120) in soils AX, HF, HN, and DD, respectively. Non-extractable ^{14}C-residues (NER) increased from 1.0, 1.5, 1.9 and 4.1% at DAT-0 to 12.6, 13.2, 16.8 and 12.5% of AR at the end of the study period. These portions of NER are comparatively low.

Table B.8.1.1.1-06 Summary of extractable and non-extractable residues

Soil		AX	HF	HN	DD
Extracted RA (%)	Day 0	97.8±0.4	97.0±0.2	97.2±0.0	97.4±0.4
	Day 120	41.3±0.2	29.3±0.4	53.4±0.5	31.5±0.3
Non-Extracted RA (%)	Day 0	1.0±0.0	1.5±0.1	1.9±0.0	4.1±0.7
	Day 120	12.6±0.1	13.2±0.1	16.8±0.3	12.5±0.1

Volatilization

The mineralization of [PYM-^{14}C] BYI 02960 was high. At the end of the study (DAT-120) up to 45.3 (AX), 58.6 (HF), 29.4 (HN) and 57.3% AR (DD) of $^{14}CO_2$ were generated. Volatile organic compounds were negligible (≤ 0.1% AR).

Transformation of Test Item

The test item declined from 97.1, 96.1, 96.5 and 93.1% AR at DAT-0 to 37.1, 24.5, 50.2 and 28.7% in soils AX, HF, HN and DD, respectively, at the end of the study. Only very minor transformation products (all were below 3% AR) were detected. In all soils three very minor metabolites, designated ROI 1, ROI 2 and ROI 3 were quantified and characterized by their chromatographic behavior. ROI 2 reached maximum levels eat DAT-59 of 2.6 (in soil AX), 0.9 (soil HF), 1.6 (soil HN) and 0.4% AR (soil DD).In the different soil ROI 1 did not exceed 1.5 (AX), 1.6 (HF), 0.8 (HN) and 1.2% AR (DD). ROI 3 was a maximum of 0.4% AR in the four soils. In soil DD, three additional very minor peaks were detected with maximum levels of 0.6% AR. The total of non-characterized extracted radioactivity did not exceed 3.1% AR. The mentioned results were included in the proposed overall pathway of degradation of BYI 02960 in soil shown in Figure B.8.1.3-01.

Kinetics of Test Item Degradation

A summary of the DT_{50} and DT_{90} calculations for the test item is given under paragraph B.8.1.2. Overall, the amount of BYI 02960 declined during the test period of 120 days. The geometric mean of the DT_{50} and the DT_{90} values for degradation of BYI 02960 in the tested soils under aerobic conditions at 20 °C were 68.8 and 331.3 days, respectively. A summary of the DT_{50} and DT_{90} calculations for the test item is given under paragraph B.8.1.2.

Conclusions

Major Outcomes of Study

The data gathered in the current laboratory investigation demonstrate that [PYM-^{14}C] BYI 02960 is degraded in the four soils. Three very minor metabolites were detected and quantified together with the test item. All further formed metabolites are regarded as transient, which is confirmed by the high mineralization rate of [PYM-^{14}C] BYI 02960 to $^{14}CO_2$ observed in this study, i.e. between 29.4 % (soil HN) and 58.6% of AR (soil HF) at the end of the study. Volatile organic compounds were very low (≤ 0.1% AR) at all sampling dates.

Table B.8.1.1.1-07 Synopsis of overall results

Soil	AX	HF	HN	DD
Total Recovery (%)	96.1 – 99.2	96.1 – 101.1	95.6 – 102.4	97.1 – 101.3
Extracted RA (%)	41.3 – 97.8	29.3 – 97.0	53.4 – 99.1	31.5 – 94.4
RA desorbed (%)	13.5 – 64.5	9.2 – 56.8	12.2 - 45.4	6.3 – 35.4
Max. CO_2 (%)	45.3	58.6	29.4	57.3
Bound Residues (%)	1.0 – 12.6	1.5 – 13.2	1.9 – 16.8	4.1 – 12.5
Extraction Efficiency of Test Substance DAT-0 (%)	97.1	96.1	96.5	93.1
Major metabolites	-	-	-	-

Significance of Results to Environmental Behaviour of BYI 02960

The current laboratory study demonstrated that [PYM-^{14}C] BYI 02960 is microbially degradable in soils under aerobic conditions. With respect to the radiolabel used mineralization to $^{14}CO_2$ is significant,

minor metabolites formed did not accumulate in soil and can therefore be regarded as transient. Non-extractable residues were low, maximum 16.8%.

Table B.8.1.1.1- 08 Synopsis of results of biotransformation of [PYM-^{14}C] BYI 02960 in soils incubated at 20 °C and 55 % of WHCmax under aerobic conditions

Soil	Laacher Hof AXXa	Hoefchen am Hohenseh	Hanscheiderhof	Dollendorf II
Soil type	Sandy loam	Silt loam	Loam	Clay loam
Major transformation products *	CO_2 (max. 58.6%) NER (comparatively low, max 16.8%)			
Minor transformation products	N/A			

*): Criteria for term "major": >10% of AR at any DAT or >5% of AR at two successive DATs or steadily increasing until the end of the study.

Remarks

The aerobic soil degradation, apart of the time dependent soption study, is acceptable and the results are reliable.

STUDY IIA, 7.1.1/02

soils	:	Four soils; sandy loam, silt loam, silt loam, silty clay	acceptability	:	**acceptable**

Summary

The biotransformation of [furanone-4-^{14}C] BYI 02960 was studied in four European soils: Laacher Hof AXXa (AX), Höfchen am Hohenseh (HF), Hanscheiderhof Plot 611 (HN), and Dollendorf II (DD) for a maximum period of 120 days under aerobic conditions in the dark at approx. 20 °C and 55% WHC_{max} (max. water holding capacity). BYI 02960 was applied at the nominal rate of 1.07 mg/kg dry weight of soil, which is equivalent to 400 g/ha field application rate.

At each sampling date, the soil samples were extracted with 2 x 80 mL acetonitrile/water (50/50, v/v), 1 x acetonitrile/water (80/20, v/v) and 1 x 80 mL acetonitrile by shaking at ambient temperature. Another extraction step was performed with acetonitrile/water (80/20, v/v) at 70°C using a microwave. The BYI 02960 residues and transformation products were analyzed and quantified by HPLC. TLC was used as confirmation method.

Material balances were complete throughout the study, and the test item declined from 96.9, 95.9, 96.4 and 94.3% of AR at DAT-0 to 37.3, 20.2, 45.2 and 26.9% at the end of the study for soils AX, HF, HN and DD, respectively. Applying double first-order kinetics a half-life (geometric mean) of 56.2 days was calculated for [furanone-4-^{14}C] BYI 02960 in the tested soils under aerobic conditions.

The mineralization of [furanone-4-^{14}C] BYI 02960 in this study was high. At the end of the study (DAT-120) up to 27.6 (soil AX), 38.9 (soil HF), 18.0 (soil HN) and 32.0% AR (soil DD) of $^{14}CO_2$ were generated. Volatile organic compounds were negligible (≤ 0.1% AR). Non-extractable ^{14}C-residues (NER) increased from 2.4, 3.8, 3.3 and 4.6% of AR at DAT-0 to 27.8, 33.6, 31.0 and 34.1% AR at the end of the study period for soils AX, HF, HN and DD, respectively. The major portions of NER radioactivity were found in the insoluble humin fraction.

Materials and methods

Materials

1. Test Item: Flupyradifurone: Code = BYI 02960; Label FUR = [Furanone-4-^{14}C] BYI 02960 (sample ID: KATH 6101); Specific activity 3.94 MBq/mg; Radiochemical purity: >98% (acc. radio-HPLC), >99% (acc. radio-TLC); Chemical purity: >98% (HPLC, UV detection at 210 nm). Identity and purity of test item in the application solution were confirmed.

2. Soil: The biotransformation of [FUR-^{14}C] BYI 2960 was studied in four different soils. These soils are representative for agricultural use areas as required by the guidelines and cover a representative range of physico-chemical properties. All soils were taken on fresh from the fields. Three days later, i.e. three days before starting the test the air dried soils were sieved through a 2 mm sieve and aliquots equivalent to 100 g dry matter were weighed into individual 300 mL Erlenmeyer flasks and fitted with trap attachments. The soils were pre-equilibrated at 20 °C in the dark.

Methods

1. Experimental conditions: The study was performed in static incubation test systems under aerobic conditions in the dark at 20.6 ± 0.3 °C. The test system consisted of Erlenmeyer flasks (300 mL) attached with a trap attachment (permeable to oxygen) containing soda lime for absorption of $^{14}CO_2$ and a polyurethane foam plug for adsorption of volatile organic compounds. Aliquots of 100 g of dry soil were weighed into the test flasks (each 28 flasks/soil). For all soils replicates were set up for each sampling (10 sampling dates including time 0, 4 spare flasks, and 1 flask for metabolite identification purposes treated with a 10x rate). Three flasks from each soil were used for determination of the microbial biomass. The final soil moisture was adjusted to 55% of WHCmax by adding deionized water.

2. Test Item Stock Solution: The entire delivered amount of [FUR-14C] BYI 02960 was dissolved in 4 mL methanol.

Table B.8.1.1.1-09 Soil physicochemical properties

Cation Exchange Capacity (CEC)	9.6 meq/100 g	13.4 meq/100 g	10.5 meq/100 g	19.2 meq/100 g
WHCmax	51.6 g H_2O/ 100 g DM	66.3 g H_2O/ 100 g DM	75.2 g H_2O/ 100 g DM	77.6 g H_2O/ 100 g DM

3. Test Item Application Solution: An application solution (total volume 60 mL) was made by diluting 2853 µL of the stock solution with 57.1 mL of purified water.

4. Mode of Application: Aliquots of 391 µL of the application solution were applied in droplets onto the 100 g pre-incubated subsamples of each soil. By the addition of the application solution, the water content was finally adjusted to 55% of WHCmax. The test vessels for DAT-0 were immediately processed for analysis. All other test vessels, including the biomass flasks which were not spiked with application solution, were fitted with trap attachments and incubated in the dark at nominal 20 ± 1°C.

[FUR-14C] BYI 02960 was applied at a rate of 416200 Bq per vessel. This corresponds to 105.63 µg per vessel which is equivalent to 99% of the application rate of 106.7 µg per vessel (calculated. a single application rate of 400 g BYI 02960 per hectare).

5. Sampling: Microbial biomass was determined prior to commencement of the test (soils sampled at the day of application), after 59 days, and at the end of the study 120 Days After Treatment (DAT-120). Entire test flasks were taken for processing and analysis at DAT-0, DAT-1, DAT-3, DAT-7, DAT-14, DAT-30, DAT-45, DAT-59, DAT-85, and DAT-120.

Prior to opening the incubation flasks (for moistening or sampling of soil), volatile (radioactive) compounds, possibly still present in the flasks, were transferred into the trap attachment by subjecting the flasks to vacuum in an excicator. At each sampling date the entire amount of soil in each test vessel was transferred into a centrifuge beaker and extracted using a mechanical shaker.

6. Description of analytical procedures: The soil processing procedure was optimized to obtain >90% extraction efficiency and >90% recovery of the test item at time zero. At each sampling date, the soil samples were extracted with 2 x 80 mL acetonitrile/water (50/50, v/v), 1 x acetonitrile/water (80/20, v/v) and 1 x 80 mL acetonitrile by shaking at ambient temperature. Another extraction step was performed with acetonitrile/water (80/20, v/v) at 70°C using a microwave.

The BYI 02960 residues and transformation products were analyzed and quantified by LSC and reversed phase radio-HPLC. Normal-phase Si-60 radio-TLC was used as a confirmatory method. The limit of quantification (LOQ) was derived from the LOD by the operation: LOQ = 3 x LOD resulting in a LOQ of about 0.9% of AR. However, values between LOD and LOQ were also used for quantification. The limit of the detection in ambient and aggressive organic extracts was in the range of 0.3% of AR. The limit of detection for a single TLC peak was estimated from the data sheets used for the comparison of the results obtained by HPLC and TLC. The lowest peaks quantified were assigned to DFA in the aggressive and account for 0.1% of AR.

The identity of the test item in stock solution and in extracts was confirmed by spectroscopic methods. In addition, spectroscopic methods were used to identify one metabolite.

Results

Results indicated that anticipated standardized conditions were maintained, and the soils were microbially active over the duration of the laboratory study (see Table B.8.1.1.1-09).

Data

The respective data for the four soils are shown in Table B.8.1.1.1-10 to Table B.8.1.1.1-13. The DAT-0 extraction efficiency was in the range of 94.6 to 97.3% of AR (mean 96.2% AR; sum of extracts only). The stability of the test item was verified by DAT 0 values of 94.3 to 96.9% AR for the soil extracts (mean 95.9% AR). These results indicate that the extraction method was appropriate to extract the applied [^{14}C]-labeled test item from the soil matrix.

Mass Balance

Material balances ranged from 95.8 to 99.7% (soil AX), 94.9 to 100.5% (soil HF), 96.9 to 100.0% (soil HN) and 94.9 to 99.6% (soil DD) of the applied radioactivity [AR]. The high material balances shown for all sampling intervals demonstrate that no significant RA dissipated from the flasks or was lost during processing.

Extractable and Bound Residues (NER)

Extractable ^{14}C-residues decreased from 97.3, 96.3, 96.7, and 94.6% AR at DAT-0 to 40.4, 23.0, 48.0 and 28.8% AR at study end (DAT-120) in soils AX, HF, HN, and DD, respectively.

Non-extractable ^{14}C-residues increased from 2.4, 3.8, 3.3 and 4.6% of AR at DAT-0 to 27.8, 33.6, 31.0 and 34.1% AR at the end of the study period for soils AX, HF, HN and DD, respectively. The major portions of non-extractable radioactivity were found in the insoluble humin fraction.

Table B.8.1.1.1-14 Summary of extractable and non-extractable residues

Soil	AX	HF	HN	DD
Extracted RA (%) Day 0	97.3±0.2	96.3±0.3	96.7±0.2	94.6±0.8
Day 120	40.4±0.6	23.0±0.5	48.0±0.4	28.8±0.3
Non-Extracted RA (%) Day 0	2.4±0.1	3.8±0.1	3.3±0.1	4.6±0.6
Day 120	27.8±0.1	33.0±0.4	31.0±0.1	34.1±0.1

Volatilization

The mineralization of [FUR-^{14}C] BYI 02960 was high. At the end of the study (DAT-120), $^{14}CO_2$ accounted for 27.6 (soil AX), 38.9 (soil HF), 18.0 (soil HN) and 32.0% (soil DD) of AR. Volatile organic compounds were not detected in significant amounts (≤ 0.1% AR).

Transformation of Test Item

The test item declined from 96.9, 95.9, 96.4 and 94.3% of AR at DAT-0 to 37.3, 20.2, 45.2 and 26.9% at the end of the study for soils AX, HF, HN and DD, respectively. Only very minor transformation products (all were below 2% AR) were detected in the extracts. Three metabolites, designated ROI 1, ROI 2 and ROI 3, were detected in all four soils and were characterized by their retention times. ROI 1 reached maximum levels of 1.2 (AX), 1.6 (HF), 1.7 (HN) and 1.7% (DD) of AR at DAT-45 or DAT-59. ROI 2 amounted to maximally 1.8 (AX), 1.5 (HF), 1.3 (HN) and 0.4% (DD) of AR with increasing amounts towards the end of the study. This metabolite was identified as BYI 02960-chloro by spectroscopic methods. ROI 3 accounted for up to 0.4 (AX), 0.5 (HF), 0.2 (HN) and 0.5% (DD) of AR, respectively. The transformation products assigned to ROI 4 and ROI 5 appeared only once with mean values of 0.4% (DD) and 0.1% (AX) of applied radioactivity, respectively. ROI 4 was tentatively identified as BYI 02960-des-difluoroethyl via co-chromatography. The total of non-characterized extracted radioactivity did not exceed 0.5% of AR.

The results were included in the proposed overall pathway of degradation of BYI 02960 in soil shown in Figure B.8.1.3-01.

Kinetics of Test Item Degradation

A summary of the DT_{50} and DT_{90} calculations for the test item is given under paragraph B.8.1.2.

Conclusions

Major Outcomes of Study

The data gathered in the current laboratory investigation demonstrate that [furanone-4-^{14}C] BYI 02960 is degraded in the four soils; a mean DT_{50} value of 56.2 days (geometric mean, n = 4 soils) was calculated. A synopsis of results is shown in Table B.8.1.1.1-15.

A few very minor metabolites were detected and quantified together with the test item. All further formed metabolites are regarded as transient, which is confirmed by the high mineralization rate of [FUR-^{14}C] BYI 02960 to $^{14}CO_2$ observed in this study, i.e. between 18.0 % (soil HN) and 38.9% of AR (soil HF) until the end of the study. Volatile organic compounds were very low (≤ 0.1% AR) at all sampling dates.

Table B.8.1.1.1-15 Synopsis of overall results

Soil	AX	HF	HN	DD
Total Recovery (%)	95.8 – 99.7	94.9 – 100.5	96.9 – 100.0	94.9 – 99.6
Extracted RA (%)	40.4 – 97.3	23.0 – 96.3	48.0 – 96.7	28.8 – 94.6
Max. CO_2 (%)	27.6	38.9	18.0	32.0
Bound Residues (%)	2.4 – 27.8	3.8 – 33.6	3.3 – 31.0	4.6 – 34.1
Extraction Efficiency on DAT-0 (%)	97.3	96.3	96.7	94.6

Significance of Results to Environmental Behavior of BYI 02960

The current laboratory study demonstrated that [FUR-^{14}C] BYI 02960 is degradable in soils under aerobic conditions. With respect to the radiolabel used mineralization to $^{14}CO_2$ is significant, however, other metabolites are not to be expected in soil, since – after their formation – they are degraded further (see Table B.8.1.1.1-16).

Table B.8.1.1.1-16 Synopsis of results of biotransformation of [FUR-^{14}C] BYI 02960 in soils incubated at 20 °C and 55 % of WHCmax under aerobic conditions

Soil	Laacher Hof AXXa	Hoefchen am Hohenseh	Hanscheiderhof	Dollendorf II
Soil type	Sandy loam	Silt loam	Silt loam	Silty clay
Major transformation products *	$^{14}CO_2$ (max. 38.9% NER (max. 34.1%)			
Minor transformation products	BYI 02960-chloro (max. 1.8%) BYI 02960-des-difluoroethyl (max. 0.4%)			

*): Criteria for term "major": >10% of AR at any DAT or >5% of AR at two successive DATs or steadily increasing until the end of the study.

Remarks

The aerobic soil degradation study is acceptable and the results are reliable.

Summary

The biotransformation of [FUR-^{14}C] BYI 02960 was studied in two US soils: silt loam Springfield, NE, and sandy loam Sanger, CA, for a maximum period of 120 days under aerobic conditions in the dark at approx. 20 °C and soil moistures maintained between pF 2.0 to 2.5. Gamma irradiated samples were investigated along with microbial active test systems. BYI 02960 was applied at the rate of 1.1 µg a.i./g soil, equivalent to 410 g a.i./ha assuming a 2.5 cm soil depth.

Duplicate test systems were analyzed at 0, 3, 7, 14, 28, 60, 92, and 120 days of incubation. The 50-g soil samples were extracted by shaking with acetonitrile:water (70:30) and acetonitrile (100%), followed by microwave extraction at 70 °C(aggressive extract) using acetonitrile:water (70:30). Extract aliquots were concentrated and analyzed by HPLC. Identification of the transformation products was performed by LC/MS, co-chromatography, and/or retention time comparison with reference standards.

Material balances were complete throughout the study, and the test item declined from 98.0 and 99.4% and of the applied amount at day 0 to 67.3 % and 30.8% of the applied at the end of the study. The first-order half-life of BYI 02960 in silt loam was 228 days. The first-order half-life in the sandy loam was 65.7 days.

BYI 02960 mineralizes relatively rapidly under aerobic condition to $^{14}CO_2$ (12.3% Springfield, 36.1% Sanger) and becomes increasingly bound to soil (16.4% Springfield, 30.6% Sanger, CA) by study end. The amount of $^{14}CO_2$ and bound residue formed in gamma-irradiated soils was significantly less than in non-sterile soils indicating a biological component to degradation and the formation of non-extractable residues from BYI 02960. Additionally, soil fractionation shows that even with extraction using strong base, BYI 02960 related residues remain bound to the solid (humin) fraction indicating very strong and irreversible binding to soil.

Materials and Methods

Materials

1. Test Item: Flupyradifurone: Code = BYI 02960; Label FUR = [Furanone-4-14C] BYI 02960 (sample ID: KATH 6252); Specific activity: 30.74 mCi/mMole; Supplied substance was repurified (vial C-1116A, 429.4 µCi/mL); the final radiochemical purity was 100%. Identity and purity of test item in the application solution were confirmed.

2. Soil: The biotransformation of [FUR-^{14}C] BYI 2960 was studied in two different soils (see Table B.8.1.1.1-17). These soils are representative for agricultural use areas as required by the guidelines and cover a representative range of physico-chemical properties. NE and CA soils were taken fresh from the fields. Each soil was collected from the top 0 to 8 inches of the field and shipped to the testing

facility subsequently. No pesticides were applied in the past 5 years to these sites where soils were collected. The NE soil was planted with alfalfa and maintained in a greenhouse prior to use (40 days). The CA soil was maintained in a walk-in refrigerator prior to use (7 days).

The soils were air dried and sieved through a 2-mm sieve. Subsequently, aliquots equivalent to 50 g dry matter were weighed into individual 250 mL glass flasks until starting the test.

Test systems were pre-equilibrated at 20 ± 1°C with soil moisture between pF 2.0 to 2.5 for six days prior to the treatment.

Methods

1. Experimental conditions: All test systems were incubated at 20 ± 1°C in the dark in a temperature-controlled environmental chamber. The test systems containing 50 g soil (dry-weight basis) consisted of a 250-mL glass flask (21 cm long and 7.2 cm internal diameter) connected to a flow-through system, containing an ethylene glycol trap for volatile organics followed by two 2 M potassium hydroxide traps for collecting CO_2 and a 1 M sulfuric acid trap for volatile acids. The headspace above the soil was continuously purged with humidified air throughout the study.

For both soils twenty test systems were treated at 1X for the kinetic study rate with each soil (1.1 µg/g; see next section). Three test systems were prepared for metabolite identification (MID) purposes, and these systems were treated at 10x the kinetic rate. MID test systems were not used for kinetic evaluation. Four control test systems were prepared as biomass test systems to demonstrate biological activity of the soil.

For the sterile portion of this study, soil was sent to Food Technology Service, Inc. (FTSI; Mulberry, FL) for gamma irradiation (actual delivered absorbed dose of 24.67 kGy). Gamma-irradiated soils were transferred to sterilized 250-mL glass flasks within a BioGuard Laminar Flow Hood using aseptic techniques. Soils were treated at the kinetic rate in the laminar flow hood using aseptic techniques, and then connected to the flow-through system. Sterility was tested at each sampling interval on each test system by plating soil dilutions on 3M Petrifilm Agar plates which were incubated at ~34°C for a minimum of 48 hours.

In total, 64 test systems were prepared. All the soils were adjusted to the appropriate moisture level for each soil, and the moisture was maintained throughout the course of the study.

2, Test Item Application Solution: The application (treatment) solution was prepared by diluting 955 µL of [FUR-^{14}C] BYI 02960 (C-1116A) with 36 mL of H_2O:MeOH (4:1) for a theoretical concentration of 0.11 µg/µL. The extensive radio-assays to determine the concentration of kinetic treatment solution resulted in 25,996,470 dpm/mL or 110 µg/mL. Radiochemical purity and identity were confirmed by HPLC and mass spectral analysis.

3. Mode and Rate of Application: Aliquots of 500-µL of the kinetic treatment solution were applied in droplets onto the 50 g pre-incubated subsamples of soils, using a 500-µL gas-tight syringe. This rate is equal to the field-use rate of 410 g a.i./ha at 2.5 cm depth and 1.5 g/cm^3 soil density. The final concentration of a.i. in each test system was 1.1 µg BYI 02960 per g soil (dry weight). By the addition the water contained the soil moisture was finally adjusted to approx. pF 2.0. Material balance for the study was based on the day 0 recovery of radioactivity (12,632,000 dpm Springfield, NE and 12,557,000 dpm Sanger, CA).

4.Test System Maintenance and Sampling: Test systems were checked for air flow through the traps and water levels in the moisture flasks. The test systems were incubated at 20 ± 1°C in the dark in an environmental chamber. The moisture loss in each system was monitored periodically by comparing the weight of the test system with the weight on Day 0. The moisture of the test systems was measured at each interval. The moisture was maintained at pF 2.5 to pF 2.0 for each soil by the addition of HPLC grade water, as needed, at periodic intervals.

Duplicate test systems were extracted and analyzed on days 0, 3, 7, 14, 28, 60, 92 and 120 days after treatment. Gamma-irradiated test systems were processed at 0, 60, 61 and 122 days after treatment.

For the sterile portion of this study, the goal was to compare the formation of bound residues with non-sterile test systems and therefore, soil extracts were radio-assayed but not analyzed by HPLC. Extracted soils were analyzed by combustion.

On the day of sampling, the test system and associated volatile traps were removed from the incubator for analysis. Prior to removing samples, the air flow was increased for approx. 15 minutes to ensure all headspace volatiles had been purged and trapped. The two KOH trap solutions were combined, volumes of the traps were recorded and triplicate aliquots were radio-assayed.

The soil was extracted and analyzed by LSC on the day of sampling. The soil extracts were analyzed by HPLC within 16 days after sample extraction. Concentrated extracts were stored in a laboratory freezer.

5. Description of analytical procedures: The soil processing procedure was optimized to obtain >90% extraction efficiency and >90% recovery of the test item at time zero. At each sampling date the entire amount of soil in each test vessel was transferred into a centrifuge bottle and extracted for 30 minutes with approximately 40 mL of acetonitrile:water (70:30, v/v) and centrifuged (5 minutes at 1850 g).

The supernatant was decanted, and the remaining soil was extracted two additional times with acetonitrile:water (70:30,v/v) followed by an extraction with approximately 40 mL of acetonitrile. The supernatants were pooled, and the volume was recorded. Extracts were radioassayed by LSC in triplicate (0.25 to 1.0 mL). An aliquot (approximately 4 mL) of the combined extracts was concentrated by a stream of nitrogen and analyzed by HPLC.

Soil remaining after the ambient acetonitrile/water and acetonitrile extractions was extracted by microwave extraction using 50 mL of acetonitrile:water (70:30, v/v) at 70°C for 10 minutes. The volume was recorded, and the extract was radioassayed by LSC in triplicate (0.25 to1.0 mL). An aliquot (approximately 4 mL) was concentrated by a stream of nitrogen and then analyzed by HPLC.

Extracted soils were air-dried under a fume hood and thoroughly homogenized. Subsamples (0.3 to 1.0 g) of the non-extracted residue (NER) were quantified by combustion.

To characterize the NER, the extracted soils from the day 92 sandy loam samples were fractionated to quantify the amounts of radioactivity associated with humic acid, fulvic acid, and humin. The BYI 02960 residues and transformation products were analyzed and quantified by LSC and radio-HPLC. Recovery of radioactivity from the HPLC column was determined by comparing radioactivity of the collected HPLC effluent (triplicate aliquots, radio-assayed) to the calculated radioactivity of the injected representative samples.

The LOD for HPLC was determined empirically by a series of injections of increasing radioactivity. The lowest amount of radioactivity detected resulted in minimum peak height of 3 times the background level in the chromatogram (520 dpm) and was considered to be the instrument LOD. The minimum amount of radioactivity injected for a sample was 3,274 dpm from the Sanger, CA day 14, replicate 2 microwave extract. This extract contained 2.8% of the applied activity which results in a LOQ of 0.4% of the applied radioactivity.

Liquid chromatography/electrospray ionization-mass spectrometry (LC/ESI-MS) and liquid chromatography/electrospray ionization-mass spectrometry/mass spectrometry analyses of standards and isolated compounds was performed.

Results and discussion

Results indicated that anticipated standardized conditions were maintained, and the soils were microbial active over the duration of the laboratory study (see Table B.8.1.1.1-17).

Data

The respective data for the two soils are shown in Table B.8.1.1.1-18 and Table B.8.1.1.1-19. The ambient and aggressive extracts were effective in extracting essentially all of the ^{14}C-residues in both soils at DAT-0, the beginning of the study (silt loam = 99.2%, sandy loam = 99.8%).

The stability of the test item was verified by DAT 0 values of 98.0 and 99.4% AR (mean of duplicates) for the soil extracts. These results indicate that the extraction method was appropriate for extraction of the applied [^{14}C]-labeled test item from the soil matrix.

Table B.8.1.1.1-18 Biotransformation of [FUR-^{14}C] BYI 02960 in silt loam Springfield (NE) under aerobic conditions; mean values and standard deviations expressed as % of AR

Compound	Days After Treatment (DAT)

Mass Balance

Material balances ranged from 98.6 to 100% (NE soil) and from 99.1 to 100.8% (CA soil) of the applied radioactivity [AR]. The high material balances shown for all sampling intervals demonstrate that no significant RA dissipated from the flasks or was lost during processing.In gamma-irradiated silt loam and sandy loam test systems, the material balances were complete as well.

Table B.8.1.1.1-20 Summary of material balances of radioactivity on four soils

Soil	Springfield	Sanger
Total Recovery (%)	100-99.6	100-100.4
Mean (%)	99.5	99.4
Relative SD (%)	0.6	0.6

Extractable and Bound Residues (NER)

Extractable ^{14}C-residues decreased from 99.2 and 99.8% of AR at DAT-0 to 70.9 and 33.7% of AR at study end (DAT-120) in NE and CA soil, respectively. In gamma-irradiated test systems extractable ^{14}C-residues only decreased from 100.8 and 99.4% of AR at DAT-0 to 90.7 and 82.4 % of AR at study end (DAT-120) in NE and CA soil, respectively.

Non-extractable ^{14}C-residues increased from 0.8 and 0.2% of AR at DAT-0 to 16.4 and 30.6% of AR at study end (DAT-120) in NE and CA soil, respectively. The majority of the NER was associated with the humin. In the sandy loam after extraction with the strong acid and base, an average of 74% still remained with the solid fraction (humin). Thus, even with exposure to strong base a significant portion of non-extractable BYI 02960 residues still remained bound to the solid phase of the soil, supporting the observations of biologically-mediated bound residues.

In gamma-irradiated test systems NER only increased from 0.3 and 0.2% of AR at DAT-0 to 6.2 and 8.7% of AR at study end (DAT-120) in NE and CA soil, respectively. Thus, NER were significantly lower in gamma-irradiated compared to non-sterile soils, indicating a biological component to the formation of bound residue.

Table B.8.1.1.1-21 Summary of extractable and non-extractable residues

Soil	Springfield	Springfield gamma-irradiated	Sanger	Sanger gamma-irradiated
Extracted RA (%) Day 0	99.2	100.8	99.8	99.4
Day 120 (122[#])	71.9	90.7	33.8	82.4
Non-Extracted RA (%) Day 0	0.8	0.3	0.2	0.2
Day 120	16.4	6.2	30.6	8.7

[#] gamma-irradiated soils

Volatilization

The mineralization of [FUR-^{14}C] BYI 02960 was high. At the end of the study (DAT-120), $^{14}CO_2$ accounted for 12.3% (NE soil) and 36.1% (CA soil) of AR. Volatile organic compounds were not detected in significant amounts (≤ 0.1% AR) throughout the study.

In gamma-irradiated test systems the mineralization of [FUR-^{14}C] BYI 02960 was low. At the end of the study (DAT-120), $^{14}CO_2$ accounted for 2.9% (NE soil) and 4.1% (CA soil) of AR, only. This indicates a biological component to the formation of $^{14}CO_2$.

Transformation of Test Item

The test item declined from 98.0 and 99.4% of AR at DAT-0 to 67.3 and 30.8% at the end of the study for soils NE and CA, respectively. Other than parent, only unidentified metabolites were measured and accounted for a maximum of 3.6 and 2.8% for soils NE and CA, respectively. The results are included in the proposed overall pathway of degradation of BYI 02960 in soil shown in Figure B.8.1.3-01.

Kinetics of Test Item Degradation

The degradation of the parent compound during the study is given under paragraph B.8.1.2.

Conclusions

Major Outcomes of Study

The data gathered in the current laboratory investigation demonstrate that BYI 02960 is degraded microbially in the soils. One part becomes increasingly bound to soil (16.4% Springfield, 30.6% Sanger) by study end. The other part is well mineralized to $^{14}CO_2$ (12.3% Springfield, 36.1% Sanger). A synopsis of results is shown in Table B.8.1.1.1-22.

All formed metabolites are regarded as transient, The mineralization rate of [FUR-^{14}C] BYI 02960 to $^{14}CO_2$ was high in this study. Volatile organic compounds were very low (≤ 0.1% AR) at all sampling dates.

The comparison of the behavior of the sterile and non-sterile soils, significantly lower amounts of bound residues and $^{14}CO_2$ in the sterile soils, indicate a biological component to the degradation / mineralization and formation of non-extractable residues from BYI 02960.

Additionally, soil fractionation shows that even with extraction using strong base, BYI 02960 related residues remain bound to the solid (humin) fraction indicating very strong and irreversible binding to soil.

Table B.8.1.1.1-22 Synopsis of overall results

Soil	Springfield Viable	Springfield Sterile	Sanger Viable	Sanger Sterile
Total Recovery (%)	98.9-100.4	98.1-101.1	99.6-100.8	95.2-99.6
Extracted RA (%)	70.9-99.2	90.7-100.8	33.7-99.8	82.4-99.4
Max. CO_2 (%)	12.3	2.9	36.1	4.1

Major metabolites	-	Not determined	-	Not determined

Significance of Results to Environmental Behavior of BYI 02960

The current laboratory study demonstrated that a viable aerobic soil environment will contribute significantly to the degradation of [FUR-^{14}C] BYI 02960. With respect to the radiolabel used mineralization to $^{14}CO_2$ is significant, however no metabolites are expected to be present in soil (see Table B.8.1.1.1-23).

Table B.8.1.1.1-23 Synopsis of results of biotransformation of [FUR-^{14}C] BYI 02960 in two soils incubated at 20 °C and pF 2.0 - 2.5 % under aerobic conditions

Soil	Springfield (NE)		Sanger (CA)	
Soil type	Silt loam		Sandy loam	
Soil status	Viable	Sterile	Viable	Sterile
DT_{50} of BYI 02960 [days]	228	Not calculated	66	Not calculated
Major transformation products *	CO_2 NER	(NER)	CO_2 (max. 36.1%) NER (max. 30.6%)	(NER)
Minor transformation products	-	CO_2	-	CO_2

*): Criteria for term "major":>10% of AR at any DAT or >5% of AR at two successive DATs or steadily increasing until the end of the study.
(NER): Major acc. to *, but did not exceed 10% of AR during the entire study period.

Remarks

The aerobic soil degradation study is acceptable and the results are reliable.

Summary

The biotransformation of [ethyl-1-^{14}C] BYI 02960 was studied in three European soils: Laacher Hof AXXa (AX), Höfchen am Hohenseh (HF), and Dollendorf II (DD) for a maximum period of approx. 120 days under aerobic conditions in the dark at approx. 20°C and 55% WHC_{max} (max. water holding capacity). BYI 02960 was applied at the nominal rate of 1.07 mg/kg dry weight of soil, which is equivalent to 400 g/ha field application rate.

At each sampling date, the soil samples were extracted with 2 x 80 mL acetonitrile/water (50/50, v/v), 1 x acetonitrile/water (80/20, v/v) and 1 x 80 mL acetonitrile by shaking at ambient temperature. Another extraction step was performed with acetonitrile/water (80/20, v/v) at 70°C using a microwave. The BYI 02960 residues and transformation products were analyzed and quantified by LCS and radio-HPLC. Radio-TLC was used as confirmation method.

Material balances were complete throughout the study, and the test substance declined from 96.0, 96.6 and 97.1% of AR at DAT-0 to 17.7, 39.6 and 23.8% of AR at the end of the study for soils DD, AX and HF, respectively. Applying double first-order kinetics a half-life (geometric mean) of 41.6 days was calculated for BYI 02960 in the tested soils under aerobic conditions.

The mineralization of [ETH-^{14}C] BYI 02960 was high. At the end of the study (DAT-118), up to 42.3 (DD), 25.9 (AX) and 33.9% AR (HF) of $^{14}CO_2$ were generated. Volatile organic compounds were not detected in significant amounts (≤ 0.1% AR).

In addition to carbon dioxide, one major transformation product was detected in the extracts of all three soils. It was identified as difluoroacetic acid (DFA) via HPLC-MS and accurate mass determination. DFA reached maximum values of 30.2, 22.0 and 33.8% of AR on DAT-45 or DAT-48 in soils DD, AX and HF, respectively. Towards the end of the study, the levels of DFA declined to 17.0, 16.3 and 23.8% of AR in soils DD, AX and HF, respectively.

Non-extractable ^{14}C-residues increased from 2.7, 2.8 and 3.2% of AR at DAT-0 to 17.9, 14.3 and 15.4% AR at the end of the study period for soils DD, AX and HF, respectively.

Materials and methods

Materials

1. Test Item: Flupyradifurone: Code = BYI 02960; Label ETH = [Ethyl-1-^{14}C] BYI 02960; Specific activity 3.93 MBq/mg; Batch ID KATH 6350 used for soil Dollendorf II on 2009-08-25; Batch KATH 6431 used soils Laacherhof AXXa and Hoefchen am Hohenseh 4a; Radiochemical purity: >98% (for

both batches); Chemical purity: >98% (for both batches); Identity and purity of test items in the application solution were confirmed.

2. Soil: The biotransformation of [ETH-^{14}C] BYI 2960 was studied in three different soils (see Table B.8.1.1.1-24). Soils Dollendorf II was taken on 2009-08-18, soils , Laacherhof AXXa and Hoefchen am Hohenseh 4a were taken on 2010-03-08 fresh from the field, and shipped subsequently. Few days later, i.e. five (DD) and four days before starting the test the gently air dried soils were sieved through a 2 mm sieve. One (soil DD) or three days (soils AX and HF) before application, aliquots equivalent to 100 g dry matter were weighed into the individual test flasks and fitted with trap attachments. Water was added in order to reach 55% of the maximum water holding capacity by the addition of application solution. The soils were pre-equilibrated at study conditions.

Methods

1. Experimental conditions: The study was performed in static incubation test systems under aerobic conditions in the dark at 19.2 ± 0.2°C (soil DD) or 20.2 ± 0.3 C (soils AX and HF) for a maximum period of 118 days. The test system consisted of Erlenmeyer flasks (300 mL) attached with a trap attachment (permeable for oxygen) containing soda lime for absorption of $^{14}CO_2$ and a polyurethane foam plug for adsorption of volatile organic compounds. Aliquots of 100 g of dry soil were weighed into the test flasks (each 23 flasks/soil). For all soils replicates were set up for each sampling (10 sampling dates including time 0, and each three flasks were used for determination of the microbial biomass. In

addition four (soil DD) and 16 (soils AX and HF) spare flasks were set up. The final soil moisture was adjusted to 55% of WHC_{max} by adding pure water.

2. Test Item Stock Solution: The entire delivered amount of [ETH-^{14}C] BYI 02960 was dissolved in 4 mL methanol. Identity and purity of test items were confirmed by HPLC-MS, HPLC-MS/MS and NMR.

3. Test Item Application Solution: The application solution for soil DD was made by diluting 1806 µL of respective stock solution with 10.2 mL of purified water, resulting in a mean concentration of 21076 Bq/20 µL. The application solution used for soils AX and HF was made by diluting 3080 µL of respective stock solution with 28.92 mL of purified water, resulting in a mean concentration of 526.4 Bq/500 µL.

4. Mode of Application: Aliquots of 398 µL of resp. application solution were applied in droplets onto the 100 g subsamples of soil Dollendorf II. In the same way aliquots of 398 µL of resp. application solution were applied onto the 100-g subsamples of soils Laacherhof AXXa and Hoefchen am Hohenseh 4a. By addition of the application solution the water content was finally adjusted to 55% of WHCmax. The test vessels for DAT-0 were immediately worked up. All other test vessels, including four reserve vessels and the biomass flasks which were not spiked with application solution, were fitted with trap attachments and incubated in the dark at nominal 20 ± 1°C. BYI 02960 was applied at a rate of 436,341.7 Bq per vessel containing soil DD and at a rate of 412,663.0 Bq per vessel containing soils AX and HF. This corresponds to 111.03 µg per DD and to 105.0 µg per AX or HF soil containing vessel, which is equivalent to 104.1% and 98.4% of the intended application rate of 106.7 µg per vessel (calculated for a single application rate of 400 g BYI 02960 per hectare).

5. Sampling: Microbial biomass was determined prior to commencement of the test (soils sampled one day before or at the day of application), after 69 or 61 days, and at the end of the study (114 or 117 days after treatment (DAT). Entire DD test flasks were taken for processing and analysis at DAT-0, DAT-1, DAT-3, DAT-7, DAT-14, DAT-30, DAT-45, DAT-62, DAT-90, and DAT-118, entire AX and HF test flasks were taken for processing and analysis at DAT-0, DAT-1, DAT-4, DAT-7, DAT-14, DAT-29, DAT-48, DAT-61, DAT-90, and DAT-117.

Prior to opening the incubation flasks (for moistening or sampling of soil), volatile (radioactive) compounds, possibly still present in the flasks, were transferred into the trap attachment by subjecting the flasks to vacuum in an exicator. At each sampling date the entire amount of soil in each test vessel was transferred into a centrifuge beaker and extracted using a mechanical shaker.

6. Description of analytical procedures: The soil processing procedure was optimized to obtain >90% extraction efficiency and >90% recovery of the test item at time zero. At each sampling date, the soil samples were extracted with 2 x 80 mL acetonitrile/water (50/50, v/v), 1 x acetonitrile/water (80/20, v/v) and 1 x 80 mL acetonitrile by 30-min shaking at ambient temperature. Another extraction step was

performed with acetonitrile/water (80/20, v/v) at 70°C using a microwave for 10 minutes. The supernatants were decanted and filtered using a folded filter. The folded filters were compressed to pills and combusted. The evolved $^{14}CO_2$ was trapped in a scintillation cocktail and analyzed for radioactivity by LSC.

The BYI 02960 residues and transformation products were analyzed and quantified by LSC and reversed phase radio-HPLC.

For HPLC analysis, 4 mL of the combined ambient organic extracts were concentrated to about 2 mL. It was confirmed by a recovery test that that no radioactivity was lost during the concentration step. The microwave extracts ("aggressive" extracts") were analyzed without any further processing. The limit of detection (LOD) in HPLC was equal to or better than 0.49% AR. Normal-phase Si-60 radio-TLC was used as confirmation method. For TLC analysis, the extracts were not processed further.

The identity of the test item in stock solution and in extracts was confirmed by spectroscopic methods. In addition, spectroscopic methods were used to identify one of the minor metabolites.

Results and discussion

Results indicated that anticipated standardized conditions were maintained, and the soils were microbial active over the duration of the laboratory study (see Table B.8.1.1.1-24).

Data

The respective data for the three soils are shown in Table B.8.1.1.1-25 to Table B.8.1.1.1-27. The DAT-0 extraction efficiency was in the range 96.5 to 97.5% of AR (mean 97.0% AR; sum of extracts only). The stability of the test item was verified by DAT 0 values of 96.0 to 97.1% AR for the soil extracts (mean 96.6% AR). These results indicate that the extraction method was well suited to extract the applied [^{14}C]-labeled test item from the soil matrix. TLC confirmed the results of the HPLC measurements for the test item and DFA.

Mass Balance

Material balances ranged from 95.5 – 100.0% (soil DD), 96.3 – 100.3% (soil AX) and 96.3 – 100.3% (soil HF) of the applied radioactivity [AR]. The high material balances shown for all sampling intervals demonstrate that no significant RA dissipated from the flasks or was lost during processing.

Extractable and Bound Residues (NER)

Extractable ^{14}C-residues decreased from 96.5, 97.0 and 97.5% AR at DAT-0 to 35.3, 57.6 and 48.6% of AR at study end in soils DD, AX and HF, respectively.

Non-extractable ^{14}C-residues increased from 2.7, 2.8 and 3.2% of AR at DAT-0 to 17.9, 15.0 and 15.4% AR at the end of the study period for soils DD, AX and HF, respectively. The major portions of radioactivity were found in the insoluble humin fraction.

Volatilization

The mineralization of [ETH-^{14}C] BYI 02960 was high. At the end of the study, $^{14}CO_2$ accounted for up to 42.3 (soil DD), 25.9 (soil AX) and 33.9% (soil HF) of AR. Volatile organic compounds were not detected in significant amounts (≤ 0.1% AR).

Transformation of Test Item

The test item declined from 96.0, 96.6 and 97.1% of AR at DAT-0 to 17.7, 39.6 and 23.0% at the end of the study for soils DD, AX and HF, respectively.

One major transformation product was detected in all three soils. It was identified as difluoroacetic acid (DFA) via HPLC-MS and accurate mass determination in ambient organic extracts originating from soil Dollendorf II. The amount of DFA reached maximum values of 30.2, 22.0 and 33.9% of AR on DAT-45 or DAT-48 in soils DD, AX and HF, respectively. At the end of the study, the amounts of DFA declined to 17.0, 16.3 and 23.8% of AR in soils DD, AX and HF, respectively.

In addition, one minor transformation product (ROI 2) was detected in all three soils with maximum amounts of 0.4 (DAT-118), 1.8 (DAT-90) and 1.6% (DAT-90) of applied radioactivity for soils DD, AX and HF, respectively. The total of unknown extracted radioactivity did not exceed 0.5% AR.

The results were included in the proposed overall pathway of degradation of BYI 02960 in soil shown in Figure B.8.1.3-01.

Kinetics of Test Item Degradation

A summary of the DT_{50} and DT_{90} calculations for the test item is given in under paragraph B.8.1.2.

Conclusions

Major Outcomes of Study

The data gathered in the current laboratory investigation demonstrate that BYI 02960 is well degraded in the four soils to form one major and one very minor metabolite. The major metabolite was identified as difluoroacetic acid (max. 33.9% of AR). The amounts of the minor metabolite detected did not exceed 1.8% of AR; no identification or characterization was made. Significant amounts of $^{14}CO_2$ (up to 42.3% AR) were measured at the end of the study indicating that mineralization of the test item and/or degradates occurred. The maximum amount of non-extractable radioactivity was 17.9% of AR.

Table B.8.1.1.1-28 Synopsis of results of biotransformation of [ETH-14C] BYI 02960 in soils incubated at 20 °C and 55 % of WHCmax under aerobic conditions)

Soil	DD	AX	HF
Total Recovery (%)	95.5-100.0	97.8-100.3	97.9-100.7
Extracted RA (%)	35.3-95.5	57.6-97.0	48.6-97.5
Max. CO_2 (%)	42.3	25.9	33.9
Bound Residues (%)	2.7-17.9	2.8-15.0	3.2-15.4
Major metabolites	DFA (30.2%)	DFA (22.0%)	DFA (33.9%)

Significance of Results to Environmental Behavior of BYI 02960

The current laboratory study demonstrated that [ETH-^{14}C] BYI 02960 is degradable in soils under aerobic conditions. With respect to the radiolabel used mineralization to $^{14}CO_2$ is highly significant. Difluoroacetic acid was detected as a further major transformation product. Other metabolites are not be expected to accumulate in soil see Table B.8.1.1.1-29.

Table B.8.1.1.1-29 Synopsis of results of biotransformation of [ETH-14C] BYI 02960 in soils incubated at 20 °C and 55 % of WHCmax under aerobic conditions

Soil	Dollendorf II	Laacher Hof AXXa	Hoefchen am Hohenseh
Soil type	Clay loam	Loamy sand	Silt loam
Major transformation products *	CO2 (max. 42.3% AR); NER (max 17.9%) DFA (max. 33.9% AR)		
Minor transformation products	-		

*): Criteria for term “major”: >10% of AR at any DAT or >5% of AR at two successive DATs or steadily increasing until the end of the study.

Remarks

The aerobic soil degradation study is acceptable and the results are reliable.

soils	:	One soils; silt loam	acceptability	:	**acceptable**

Summary

The biotransformation of [pyridine-2,6-^{14}C] BYI 02960 was studied in one soil, Höfchen am Hohenseh 4a (HF, Burscheid, Germany), a silt loam soil of pH 6.5 ($CaCl_2$) and 2.4% organic carbon content. The

incubation was conducted for max. 117 days under aerobic conditions in the dark at ca. 20°C and 55% WHC_{max} (max. water holding capacity). BYI 02960 was applied at the nominal rate of 106.7 µg/ 100 g soil, which is equivalent to a field application rate of 400 g/ha.

At each sampling date, i.e. 0, 1, 4, 7, 14, 29, 48, 61, 90 and 117 days after treatment (DAT), the duplicate soil samples were extracted with 2 x 80 mL acetonitrile/water (50/50, v/v), 1 x acetonitrile/water (80/20, v/v) and 1 x 80 mL acetonitrile by shaking at ambient temperature. Another extraction step was performed with acetonitrile/water (80/20, v/v) at 70°C using a microwave. The BYI 02960 residues and transformation products were analyzed and quantified by LCS and radio-HPLC. Radio-TLC was used as a confirmatory method.

Material balances were complete throughout the study (ranged on mean from 94.1 to 100.3% of AR), and the test substance declined from 96.7% at DAT-0 to 24.6% of AR at the end of the study.

The mineralization of [PYR-^{14}C] BYI 02960 was high. At the end of study (DAT-117), $^{14}CO_2$ accounted for 57.4% of AR. Volatile organic compounds were not detected in significant amounts (≤ 0.1% AR).

Only minor transformation products (all mean values were ≤ 2.5% of AR) were detected in the extracts and were characterized by their retention time. The transformation product assigned to ROI 2 reached a mean maximum level of 2.0% of AR at DAT-48. The maximum amount of the second transformation product (ROI 3) was detected on DAT-7 (2.5% of AR). Towards the end of the study, the amounts decreased below the detection limit. ROI 3 was identified as 6-chloronicotinic acid (6-CNA) by co-chromatography. The third minor transformation product was detected only once (DAT-48, 0.3% of AR). Non-extractable ^{14}C-residues increased from 3.3% of AR at DAT-0 to 16.7% of AR at the end of the study period.

Materials and methods

Materials

1. Test Item: Flupyradifurone: Code = BYI 02960; Label PYR = [Pyridine-2,6-^{14}C] BYI 02960 (sample ID: KATH 6432); Specific activity: 4.49 MBq/mg ;Radiochemical purity: >98% (acc. radio-HPLC and radio-TLC; Chemical purity: >98% (HPLC, UV detection at 210 nm); Identity and purity of test item in the application solution were confirmed.

2. Soil: The biotransformation of BYI 02960 was studied in one soil.. The soil was taken fresh from the field. On the day of sampling, the soil was broken up stepwise and gently air dried. Then, the soil was successively sieved to ≤ 2 cm, filled into plastic bags and stored in a climatic cabinet at 20 ± 2°C.

100 g aliquots (dry matter) of the sieved soil were weighed into individual 300 mL Erlenmeyer flasks. Water was added in order to finally reach 55% of the maximum water holding capacity by the addition of application solution (353 µL) on the day of application.

Three additional test systems were prepared which were used for microbial biomass determinations. Since no application solution was added to these vessels, they were directly adjusted to 55% of maximum water holding capacity. All vessels were fitted with trap attachments and pre-equilibrated at 20 ± 2°C in the dark for three days.

Table B.8.1.1.1-30 Soil physicochemical properties

WHCmax	64.7 g H2O/ 100 g DM

Methods

1. Experimental conditions: The study was performed in static incubation test systems under aerobic conditions in the dark at 20.2 ± 0.3 °C. The test system consisted of Erlenmeyer flasks (300 mL) attached with a trap attachment (permeable for oxygen) containing soda lime for absorption of $^{14}CO_2$ and a polyurethane foam plug for adsorption of volatile organic compounds. Aliquots of 100 g of dry soil were weighed into the test flasks. Replicates were set up and processed for each sampling (10 sampling dates including time 0, and 16 spare flasks were set up but not further processed in this study). Three flasks were used for determination of the microbial biomass. The final soil moisture was adjusted to 55% of WHC_{max} by adding pure water.

2. Test Item Stock Solution: The entire delivered amount of [pyridine-2,6-^{14}C] BYI 02960 was dissolved in 4 mL methanol.

3. Test Item Application Solution: An application solution was made by diluting 2048 µL of before-mentioned stock solution with 9.952 mL of purified water.

4. Mode of Application: Aliquots of 353 µL of the application solution were applied in droplets onto the 100 g pre-incubated subsamples of each soil. By the addition of the application solution, the water content was finally adjusted to 55% of WHC_{max}. The test vessels for DAT-0 were immediately processed for analysis. All other test vessels, including the biomass flasks which were not spiked with application solution, were fitted with trap attachments and incubated in the dark at nominal 20 ± 2°C.

[PYR-^{14}C] BYI 02960 was applied at a rate of 415954 Bq per vessel. This corresponds to 92.64 µg per vessel which is equivalent to 86.8% of the intended application rate of 106.7 µg per vessel (calculated for a single application rate of 400 g BYI 02960 per hectare).

5. Sampling: Microbial biomass was determined prior to commencement of the test (soils sampled at the day of application), after 61 days, and at the end of the study 117 days after treatment (DAT-117). Entire test flasks were taken for processing and analysis at DAT-0, DAT-1, DAT-4, DAT-7, DAT-14, DAT-29, DAT-48, DAT-61, DAT-90, and DAT-117.

Prior to opening the incubation flasks (for moistening or sampling of soil), volatile (radioactive) compounds, possibly still present in the flasks, were transferred into the trap attachment by subjecting the flasks to vacuum in a desiccator. At each sampling date the entire amount of soil in each test vessel was transferred into a centrifuge beaker and extracted using a mechanical shaker.

6. Description of analytical procedures: The soil processing procedure was optimized to get >90% extraction efficiency and >90% recovery of the test item at time zero. At each sampling date, the soil samples were extracted with 2 x 80 mL acetonitrile/water (50/50, v/v), 1 x acetonitrile/water (80/20, v/v) and 1 x 80 mL acetonitrile by shaking at ambient temperature. Another extraction step was performed with acetonitrile/water (80/20, v/v) at 70°C using a microwave.

The BYI 02960 residues and transformation products were analyzed and quantified by LSC and reversed phase radio-HPLC. Losses of radioactivity after concentration of extracts were minimal. Normal-phase Si-60 radio-TLC was used as confirmation method. The identity of the test item in stock solution and in extracts was confirmed by spectroscopic methods. In addition, spectroscopic methods were used to identify one of the minor metabolites.

Results and discussion

Results indicated that anticipated standardized conditions were maintained, and the soils were microbial active over the duration of the laboratory study (see Table B.8.1.1.1-30).

Data

The data for the soil are shown in Table B.8.1.1.1-31. The DAT-0 extraction efficiency was 96.7% of AR (ambient extracts 95.0% of AR). The stability of the test item was verified by a DAT-0 recovery of

96.3 ± 0.7% of AR. These results indicate that the extraction method was well suited to extract the applied [^{14}C]-labeled test item from the soil matrix.

n.d. = not detected; n.a. = not analyzed; ROI = region of interest; ROI 3 was identified as compound 6-CNA

Mass Balance

Material balance ranged from 94.1 ±0.3 to 100.3 ±0.8% of the applied radioactivity [AR]. The high material balances shown for all sampling intervals demonstrate that no significant RA dissipated from the flasks or was lost during processing.

Extractable and Bound Residues (NER)

Extractable ^{14}C-residues decreased from 96.7 ±0.8% at DAT-0 to 24.6 ±0.4% of AR at study end (DAT-117). Non-extractable ^{14}C-residues increased from 3.3 ±0.0% at DAT-0 to 16.2 ±0.1% of AR at the end of the study period.

Volatilization

The mineralization of BYI 02960 was high. At the end of the study (DAT-117), $^{14}CO_2$ accounted for 57.4 ±0.5% of AR. Volatile organic compounds were not detected in significant amounts (< 0.1% AR).

Transformation of Test Item

The test item declined from 96.3 ±0.7% of AR at DAT-0 to 22.7 ±0.5% of AR at the end of the study. Three minor transformation products were detected in the extracts. The transformation product assigned to ROI 2 reached a maximum level of 2.0% of AR at DAT-48. The amount of the second transformation product (ROI 3) increased to a maximum amount of 2.5% of AR on DAT-7 and

decreased below the detection limit towards the end of the study. This transformation product was identified as 6-chloronicotinic acid (6-CNA) by co-chromatography. The third minor transformation product was detected only once (DAT-48), accounting for 0.3% of AR.

The total of unknown extracted radioactivity did not exceed 0.5% of AR and was assigned to the background signal in the HPLC-analysis. The mentioned results were included in the proposed overall pathway of degradation of BYI 02960 in soil shown in Figure B.8.1.3-01.

Kinetics of Test Item Degradation

A summary of the DT_{50} and DT_{90} calculation for the test item is given in paragraph B.8.1.2.

Conclusions

Major Outcomes of Study

The data gathered in the current laboratory investigation demonstrate that BYI 02960 is degraded in HF soil. A synopsis of results is shown by Table B.8.1.1.1-32. A few very minor metabolites were detected and quantified together with the test item. All further formed metabolites are regarded as transient, which is confirmed by the high mineralization rate of [PYR-^{14}C] BYI 02960 to $^{14}CO_2$ observed in this study, i.e. 57.4% of AR until the end of the study. Volatile organic compounds were very low (≤ 0.1% AR) at all sampling dates.

Significance of Results to Environmental Behavior of BYI 02960

The current laboratory study demonstrated that [PYR-^{14}C] BYI 02960 is degradable in soil under aerobic conditions. With respect to the radiolabel used mineralization to $^{14}CO_2$ is significant, however, significant metabolites are not expected to be present in soil, since – after their formation – they are well mineralized (see Table B.8.1.1.1-32).

Table B.8.1.1.1-32 Synopsis of results of biotransformation of [PYR-^{14}C] BYI 02960 in soil HF incubated at 20 °C and 55 % of WHCmax under aerobic conditions

Soil	**Hoefchen am Hohenseh 4a**
Soil type	Silt loam
Major transformation products *	CO_2 (max. 57.4%) NER (max. 16.7%)
Minor transformation products	6-CNA (max. 2.5%)

*): Criteria for term "major": >10% of AR at any DAT or >5% of AR at two successive DATs or steadily increasing until the end of the study.

Remarks

The aerobic soil degradation study is acceptable and the results are reliable.

Summary

The biotransformation of [pyridine-2,6-^{14}C] BYI 02960 was studied in two US soils, silt loam Springfield, NE, and sandy loam Sanger, CA, for a maximum period of 120 days under aerobic conditions in the dark at approx. 20 °C and soil moistures maintained between pF 2.0 to 2.5. Gamma irradiated samples were investigated along with microbial active test systems. BYI 02960 was applied at the rate of 1.1 µg a.i./g soil, equivalent to 410 g a.i./ha assuming a 2.5 cm soil depth.

Duplicate test systems were analyzed at 0, 3, 7, 14, 28, 60, 92, and 120 days of incubation. The 50-g soil samples were extracted by shaking with acetonitrile:water (70:30) and acetonitrile (100%), followed by microwave extraction at 70 °C(aggressive extract) using acetonitrile:water (70:30). Extract aliquots were concentrated and analyzed by HPLC. Identification of the transformation products was performed by LC/MS, co-chromatography, and/or retention time comparison with reference standards.

Material balances were complete throughout the study, and the test item declined from 97.4 and 98.6% and of the applied amount at day 0 to 65.5 and 30.0% of the applied at the end of the study. In the silt loam, extractable ^{14}C-residues decreased from 99.3% of the applied amount at day 0 to 67.0% of the applied at the end of the study. Non-extractable 14C-residues increased from 0.7% of the applied amount at day 0 to a maximum of 11.3% at day 120. At study termination, evolved $^{14}CO_2$ reached 20.2%, and radioactive volatile organics were not detected. Total unidentified radioactivity ranged from 0.0% to 2.4% of the applied amount.

In the sandy loam, extractable ^{14}C-residues decreased from 99.9% of the applied amount at day 0 to 40.0% of the applied at the end of the study. One major degradate was identified as 6-chloronicotinic acid (6-CNA), which formed 6.9% on day 14, reached a maximum of 17.1% on day 60, and declined to 8.2% by the end of the study.

In the sterile silt loam, extractable 14C-residues decreased from 99.1% of the applied amount at day 0 to 89.4% of the applied at the end of the study. Non-extractable 14C-residues increased from 0.9% of the applied amount at day 0 to a maximum of 6.2% at day 122. At study termination, evolved $^{14}CO_2$ reached 0.4%, and radioactive volatile organics were not detected.

In the sterile sandy loam, extractable 14C-residues decreased from 99.8% of the applied amount at day 0 to 85.8% of the applied at the end of the study. Non-extractable ^{14}C-residues increased from 0.2% of the applied amount at day 0 to a maximum of 9.3% at day 122. At study termination, evolved $^{14}CO_2$ reached 0.9%, and radioactive volatile organics were not detected.

[PYR-^{14}C] BYI 02960 mineralizes relatively rapidly under aerobic condition to $^{14}CO_2$ (20.2% Springfield, 36.1% Sanger) and becomes increasingly bound to soil (11.3% Springfield, 25.5% Sanger, CA) by study end. Total unidentified radioactivity ranged from 0.0% to 2.4% (Springfield) and 0.0% to 3.0% (Sanger) of the applied amount.

The amount of $^{14}CO_2$ and bound residue formed in gamma-irradiated soils was significantly less than in non-sterile soils indicating a biological component to degradation and the formation of non-extractable residues from BYI 02960. Additionally, soil fractionation shows that even with extraction using strong base, BYI 02960 related residues remain bound to the solid (humin) fraction indicating very strong and irreversible binding to soil.

Materials and methods

Materials

1. Test Item: Flupyradifurone: Code = BYI 02960; Label PYR = [pyridine-2,6-^{14}C] BYI 02960 (Vial C-1135);Specific activity: 35.03 mCi/mMole; Radiochemical purity: >98%; Identity and purity of test item in the application solution were confirmed.

2. Soil: The biotransformation of [PYR-^{14}C] BYI 2960 was studied in two different soils NE and CA soils were taken fresh from the fields. Each soil was collected from the top 0 to 8 inches of the field and shipped to the testing facility subsequently. No pesticides were applied in the past 5 years to these sites where soils were collected.

The NE soil was stored under refrigeration for 8 days, transferred to a greenhouse and stored under crop cover (alfalfa) and after it was sieved with 2-mm sieve before use. The CA soil was maintained in a walk-in refrigerator prior to use at 3.9 ±0.8°C, sieved with 2-mm sievebefore use.

Aliquots equivalent to 50 g dry matter were weighed into individual 250 mL glass flasks until starting the test. Test systems were pre-equilibrated at 20 ± 1°C and soil moisture between pF 2.0 to 2.5 for six days prior to the treatment.

Methods

1. Experimental conditions: All test systems were incubated at 20 ± 1°C in the dark in a temperature-controlled environmental chamber. The test systems containing 50 g soil (dry-weight basis) consisted of a 250-mL glass flask (21 cm long and 7.2 cm internal diameter) connected to a flow-through system, containing an ethylene glycol trap for volatile organics followed by two 2 M potassium hydroxide traps for collecting CO_2 and a 1 M sulfuric acid trap for volatile acids. The headspace above the soil was continuously purged with humidified air throughout the study.

For both soils twenty test systems were treated at 1X for the kinetic study rate with each soil (1.1 µg/g) Three test systems were prepared for metabolite identification (MID) purposes, and these systems were treated at 10x the kinetic rate. MID test systems were not used for kinetic evaluation. Four control test systems were prepared as biomass test systems to demonstrate biological activity of the soil.

For the sterile portion of this study, soil was sent out for gamma irradiation (actual delivered absorbed dose of 24.67 kGy). Gamma-irradiated soils were transferred to sterilized 250-mL glass flasks within a BioGuard Laminar Flow Hood using aseptic techniques. Soils were treated at the kinetic rate in the laminar flow hood using aseptic techniques, and then connected to the flow-through system. Sterility was tested at each sampling interval on each test system by plating soil dilutions on 3M Petrifilm Agar plates which were incubated at ~35°C for a minimum of 48 hours.

In total, 64 test systems were prepared. All the soils were adjusted to the appropriate moisture level for each soil, and the moisture was maintained throughout the course of the study.

2. Test Item Application Solution: The application (treatment) solution was prepared by diluting 975 µL of [PYR-^{14}C] BYI 02960 (C-1135) with 37.5 mL of H_2O:MeOH (4:1) for a theoretical concentration of 0.11 µg/µL. The extensive radio-assays to determine the concentration of kinetic treatment solution resulted in 31,227, 300 dpm/mL or 116 µg/mL; the radiochemical purity and identity were confirmed by HPLC and mass spectral analysis.

3. Mode and Rate of Application: On 2010-01-25, aliquots of 480-µL of the kinetic treatment solution were applied in droplets onto the 50 g pre-incubated subsamples of soils, using a 500-µL gas-tight syringe. This rate is equal to the field-use rate of 410 g a.i./ha at 2.5 cm depth and 1.5 g/cm^3 soil density. The final concentration of a.i. in each test system was 1.1 µg BYI 02960 per g soil (dry weight). By the addition the water contained the soil moisture was finally adjusted to approx. pF 2.0. Material balance for the study was based on the day 0 recovery of radioactivity (14,495,777 dpm for Springfield, NE and 14,438,374 dpm for Sanger, CA).

4. Test System Maintenance and Sampling: Test systems were checked for air flow through the traps and water levels in the moisture flasks. The test systems were incubated at 20 ± 1°C in the dark in an environmental chamber. The moisture loss in each system was monitored periodically by comparing the weight of the test system with the weight on Day 0. The moisture of the test systems was measured at each interval. The moisture was maintained at pF 2.5 to pF 2.0 for each soil by the addition of HPLC grade water, as needed, at periodic intervals.

Duplicate test systems were extracted and analyzed on days 0, 3, 7, 14, 28, 60, 92 and 120 days after treatment. Gamma-irradiated test systems were processed at 0, 60 and 122 days after treatment. For the sterile portion of this study, the goal was only to compare the formation of bound residues with non-sterile test systems and therefore, soil extracts were radio-assayed but not analyzed by HPLC. Extracted soils were analyzed by combustion.

On the day of sampling, the test system and associated volatile traps were removed from the incubator for analysis. Prior to removing samples, the air flow was increased for approx. 15 minutes to ensure all headspace volatiles had been purged and trapped. The two KOH trap solutions were combined, volumes of the traps were recorded and triplicate aliquots were radio-assayed.

The soil was extracted and analyzed by LSC on the day of sampling. The soil extracts were analyzed by HPLC within 27 days after sample extraction. Concentrated extracts were stored in a laboratory freezer.

5. Description of analytical procedures: The soil processing procedure was optimized to get >90% extraction efficiency and >90% recovery of the test item at time zero. At each sampling date the entire amount of soil in each test vessel was transferred into a centrifuge bottle and extracted for 30 minutes with approximately 40 mL of acetonitrile:water (70:30, v/v) using a horizontal shaker, and centrifuged (5 minutes at 1850 g).

The supernatant was decanted, and the remaining soil was extracted two additional times with acetonitrile:water (70:30,v/v) followed by an extraction with approximately 40 mL of acetonitrile. The supernatants were pooled, and the volume was recorded. Extracts were radioassayed by LSC in

triplicate (0.25 to 1.0 mL). An aliquot (approximately 4 mL) of the combined extracts was concentrated by a stream of nitrogen and analyzed by HPLC.

Soil remaining after the ambient acetonitrile/water and acetonitrile extractions was extracted by microwave extraction using 50 mL of acetonitrile:water (70:30, v/v) at 70°C for 10 minutes. The volume was recorded, and the extract was radioassayed by LSC in triplicate (0.25 to1.0 mL). An aliquot (approximately 4 mL) was concentrated by a stream of nitrogen and then analyzed by HPLC.

Extracted soils were air-dried under a fume hood and thoroughly homogenized. Subsamples (0.3 to 1.0 g) of the non-extracted residue (NER) were quantified by combustion.

To characterize the NER, the extracted soils from the day 92 sandy loam samples were fractionated to quantify the amounts of radioactivity associated with humic acid, fulvic acid, and humin.

The BYI 02960 residues and transformation products were analyzed and quantified by LSC and radio-HPLC. Recovery of radioactivity from the HPLC column was determined by comparing radioactivity of the collected HPLC effluent (triplicate aliquots, radio-assayed) to the calculated radioactivity of the injected representative samples.

The LOD for HPLC was determined empirically by a series of injections of increasing radioactivity. The lowest amount of radioactivity detected resulted in minimum peak height of 3 times the background level in the chromatogram (520 dpm) and was considered to be the instrument LOD. The minimum amount of radioactivity injected for a sample was 6,034 dpm from the sandy loam day 120, replicate 1 microwave extract. This extract contained 2.5% of the applied activity which results in a LOQ of 0.2% of the applied radioactivity.

Liquid chromatography/electrospray ionization-mass spectrometry (LC/ESI-MS) and LC/ESI-MS/MS analyses of standards and isolated compounds was performed using a triple quadrupole mass spectrometer interfaced to an quaternary HPLC system (Thermo Electron).

Results and discussion

Results indicated that anticipated standardized conditions were maintained, and the soils were microbial active over the duration of the laboratory study (see Table B.8.1.1.1-33). For the gamma irradiated soils, sterility was lost during the study indicated by plate counts. However, results indicate the biological activity was compromised, as evidenced by the significant reduction in $^{14}CO_2$ formation in the sterile soils at the end of the study.

Data

The respective data for the four soils are shown in Table B.8.1.1.1-34 and Table B.8.1.1.1-35. The ambient and aggressive extracts were effective in extracting essentially all of the ^{14}C-residues in both soils at DAT-0, the beginning of the study (silt loam = 99.3%, sandy loam = 99.9%). The stability of the test item was verified by DAT 0 values of 97.4 and 98.6% AR (mean of duplicates) for the soil extracts These results indicate that the extraction method was very well suited to extract the applied [^{14}C]-labeled test item from the soil matrix.

a) No individual peak accounted to more than 2.4%.
b) Aggressive extracts were not analyzed since the RA content was less than 3% of total applied.

Mass Balance

Material balances ranged from 98.4 to 100% (NE soil) and from 98.9 to 101.6% (CA soil) of the applied radioactivity [AR]. The high material balances shown for all sampling intervals demonstrate that no

significant RA dissipated from the flasks or was lost during processing.In gamma-irradiated silt loam and sandy loam test systems, the material balances were complete as well.

Extractable and Bound Residues (NER)

Extractable ^{14}C-residues decreased from 99.3 and 99.9% of AR at DAT-0 to 67.0 and 40.0% of AR at study end (DAT-120) in NE and CA soil, respectively.

In gamma-irradiated test systems extractable ^{14}C-residues only decreased from 99.1 and 99.8% of AR at DAT-0 to 89.4 and 85.8 % of AR at study end (DAT-120) in NE and CA soil, respectively.

Non-extractable ^{14}C-residues increased from 0.7 and 0.1% of AR at DAT-0 to 11.3 and 25.5% of AR at study end (DAT-120) in NE and CA soil, respectively. The majority of the NER was associated with the humin. In the sandy loam after extraction with the strong acid and base, an average of 60% still remained with the solid fraction (humin). Thus, even with exposure to strong base a significant portion of non-extractable BYI 02960 residues still remained bound to the solid phase of the soil, supporting the observations of biologically-mediated bound residues.

In gamma-irradiated test systems NER only increased from 0.2 and 0.0% of AR at DAT-0 to 6.2 and 9.3% of AR at study end (DAT-120) in NE and CA soil, respectively. Thus, NER were significantly lower in gamma-irradiated compared to non-sterile soils, indicating a biological component to the formation of bound residue.

Table B.8.1.1.1-36 Summary of extractable and non-extractable residues

Soil	Springfield	Springfield gamma-irradiated	Sanger	Sanger gamma-irradiated

[#] gamma-irradiated soils

Volatilization

The mineralization of [PYR-^{14}C] BYI 02960 was high. At the end of the study (DAT-120), $^{14}CO_2$ accounted for 20.2% (NE soil) and 36.1% (CA soil) of AR. In gamma-irradiated test systems the mineralization of [FUR-^{14}C] BYI 02960 was low. At the end of the study (DAT-120), $^{14}CO_2$ only accounted for 0.4% (NE soil) and 0.9% (CA soil) of AR,. This indicates a biological component to the formation of $^{14}CO_2$. Volatile organic compounds were not detected in significant amounts (≤ 0.1% AR) throughout the study.

Transformation of Test Item

The test item declined from 97.4 and 98.6% of AR at DAT-0 to 65.5 and 30.0% at the end of the study for soils NE and CA, respectively.

In silt loam, other than parent, unidentified metabolites were measured and accounted for a maximum of 2.4%. In sandy loam, other than parent, one major degradate was identified as 6-chloronicotinic acid, which was formed 6.9% on day 14, reached a maximum of 17.1% on day 60, and declined to 8.2% by the end of the study. The total unidentified radioactivity accounted for a maximum of 3.0% of the applied amount.

The mentioned results were included in the proposed overall pathway of degradation of BYI 02960 in soil shown in Figure B.8.1.3-01.

Kinetics of Test Item Degradation
The degradation of the parent compound during the study is given in paragraph B.8.1.2.

Conclusion
Major Outcomes of Study
A synopsis of results is shown in Table B.8.1.1.1-37. The data gathered in the current laboratory investigation demonstrate that [PYR-^{14}C] BYI 02960 is degraded moderately rapid in the two soils;. One part of the residues becomes increasingly bound to soil (11.3% Springfield, NE, 25.5% Sanger, CA) by study end. The other part is well mineralized to $^{14}CO_2$ (20.2% Springfield, NE, 36.1% Sanger, CA). In the Sanger soil one interim metabolite, which was identified as 6-chloronicotinic acid, was to be observed, reaching its maximum of 17.1% on day 60 and declining to 8.2% of AR by the end of the study. All further formed metabolites are regarded as transient, which is confirmed by the high mineralization rate of [PYR-^{14}C] BYI 02960 to $^{14}CO_2$ observed in this study. Volatile organic compounds were very low (≤ 0.1% of AR) at all sampling dates.

Degradation, amount of bound residues as well as of $^{14}CO_2$ formed in gamma-irradiated soils was significantly less than in non-sterile soils, indicating a biological component to the degradation/ mineralization and formation of non-extractable residues from BYI 02960.

Additionally, soil fractionation shows that even with extraction using strong base, BYI 02960 related residues remain bound to the solid (humin) fraction indicating very strong and irreversible binding to soil.

Table B.8.1.1.1-37 Synopsis of overall results

Soil	Springfield Viable	Springfield Sterile	Sanger Viable	Sanger Sterile
Total Recovery (%)	100-99.6	96-100.0	100-100.4	96.0-100.0
Extracted RA (%)	70.9-99.2	89.4-99.1	33.7-99.8	85.8-99.8
Max. CO_2 (%)	12.3	0.4	36.1	0.9

Bound Residues (%)	0.8-16.4	0.9-6.2	0.2-30.6	0.2-9.3
Major metabolites	-	Not determined	6-CNA (17.1%)	Not determined

Significance of Results to Environmental Behavior of BYI 02960

The current laboratory study demonstrated that a viable aerobic soil environment will contribute significantly to the degradation of [PYR-^{14}C] BYI 02960. With respect to the radiolabel used mineralization to $^{14}CO_2$ is significant. One metabolite, which was identified as 6-chloronicotinic acid, was observed at a proportion of greater 10% of applied, and declined to the end of study. Other metabolites are not to be expected to be significant in soil, since – after their formation – they are well mineralized (see Table B.8.1.1.1-38).

Table B.8.1.1.1-38 Synopsis of results of biotransformation of [PYR-^{14}C] BYI 02960 in two soils incubated at 20 °C and pF 2.0 – 2.5 % under aerobic conditions

Soil	**Springfield (NE)**		**Sanger (CA)**	
Soil type	**Silt loam**		**Sandy loam**	
Soil status	**Viable**	**Sterile**	**Viable**	**Sterile**
Major transformation products *	CO_2 (max. 20.2%) NER (max. 11.3%)	(NER)	CO_2 (max. 36.1%) NER (max. 25.5%) 6-CNA (max. 17.1%)	(NER)
Minor transformation products	-	CO_2	-	CO_2

*): Criteria for term "major": >10% of AR at any DAT or >5% of AR at two successive DATs or steadily increasing until the end of the study.
(NER): Major acc. to *, but did not exceed 10% of AR during the entire study period.

Remarks

The aerobic soil degradation study is acceptable and the results are reliable.

Summary

The present laboratory study investigated the degradation of BYI 02960 in one soil (silt loam) under flooded anaerobic conditions. [Pyridine-2,6-^{14}C], [furanone-4-^{14}C] and [ethyl-1-^{14}C] BYI 02960 (equivalent to label PYR, FUR, and ETH, respectively) were applied at of 110.1, 104.6 and 105.9 µg/100 g soil (dry matter), i.e. equivalent to 103.2, 98.0 and 99.2% of the nominal application rate of 400 g/ha.

The soil in duplicate test flasks/interval was maintained under aerobic conditions for 30 days in the dark at 20 ± 2°C and approx. 55% of the maximum water holding capacity. Following the aerobic phase, the samples were flooded with oxygen-depleted de-ionized water (approx. 3 cm layer above soil level), set under nitrogen atmosphere, and maintained in the dark at 20 ± 2°C under anaerobic conditions for max. 123 days. During the aerobic study phase, air-permeable traps were attached for the collection of CO_2 and volatile organics (static test system design). At start of the anaerobic study phase, the trap systems were replaced by sealable two-valve glass stoppers connected with plastic gas sampling bags.

Soil samples and water layers were separated by decanting to allow for individual analysis. The soil was extracted four times with at ambient temperature (combined as "ambient organic extract"). Subsequently, the soil was extracted once at an elevated temperature ("aggressive extract"). BYI 02960 residues in water layers were directly analyzed by reversed phase HPLC; the soil extracts were subjected to solvent exchange prior to analysis (all labels). TLC was employed as second contrasting separation method for the confirmation of the results. A limit of quantification (LOQ) of equal or better than 0.9% of the applied radioactivity (% AR) was calculated for HPLC radioactivity detection within the sample matrices.

For all three radiolabels complete material balances found at all sampling intervals demonstrated that no significant portion of radioactivity dissipated from the flasks or was lost during processing. During the 30 days of aerobic incubation $^{14}CO_2$ accounted for up to 26.7 (PYR), 15.9 (FUR) and 6.9 % of AR (ETH). During the anaerobic incubation phase, mineralization to $^{14}CO_2$ was negligible (< 0.1 % of AR). Organic volatiles were not observed in the aerobic or in the anaerobic study phase (< 0.1 % AR at all sampling intervals).

The radioactivity extractable from soil decreased to 55.9, 55.2 and 82.0% of AR towards the end of the aerobic incubation phase (DAT-30), and further to 41.5, 40.2 and 53.4% of AR until the end of the anaerobic incubation period for labels PYR, FUR and ETH, respectively.

Within the aerobic phase of the study (30 days) the percentages of BYI 02960 in the entire systems decreased to 53.7, 52.6 and 54.7% of AR for labels PYR, FUR and ETH, respectively. During the anaerobic incubation period (i.e. flooded state) the portions of BYI 02960 slightly decreased further to 47.8, 47.2 and 47.7% of AR for labels PYR, FUR and ETH, respectively.

Only one transformation product exceeded 5% of AR over the entire study period. It was detected in the test systems of label ETH and it was identified as difluoroacetic acid (DFA). DFA levels increased to a level of 25.1% of AR during the initial 30 days of aerobic conditions. During the anaerobic phase, the amounts of DFA remained more or less stable (24.2 - 26.2% of AR).

In the aerobic incubation phase, non-extractable residues (NER) in soil increased from 2.7 to 12.9% (label PYR), 3.1 to 25.6% (Label FUR) and 2.8 to 10.8% of AR (Label ETH). During the anaerobic incubation phase the NER slightly increased further.

Applying single first order kinetics (SFO) to the BYI 02960 residues in the entire systems during the anaerobic phase of the study, the estimated DT_{50} values range from 581.8 to 693.2 days (geometric mean: 633.7 days).

Based on the results obtained within this study it can be expected that the amounts of BYI 02960 and its only significant metabolite DFA remain stable under flooded field conditions. Degradation would be expected to continue whenever the conditions become aerobic.

Materials and methods

Materials

1. Test Items: Flupyradifurone: Code = BYI 02960;
Label PYR = [Pyridine-2,6-^{14}C] BYI 02960 (sample ID: KATH 6403); Specific activity: 4.49 MBq/mg; Radiochemical purity: >98% (acc. radio-HPLC)
Label FUR = [Furanone-4-^{14}C] BYI 02960 (sample ID: KATH 6405); Specific activity: 3.94 MBq/mg Radiochemical purity: >98% (acc. radio-HPLC).
Label ETH = [Ethyl -1-^{14}C] BYI 02960 (sample ID: KATH 6404); Specific activity: 3.93 MBq/mgRadiochemical purity: >99% (acc. radio-HPLC)
Identity and purity of test items in the application solution were confirmed.

2. Soil: the biotransformation of BYI 02960, under anaerobic conditions, was studied in one soil. The soil was taken on 2009-12-07 fresh from the field. On the day of sampling, the soil was broken up stepwise and gently air dried. Then, the soil was successively sieved to ≤ 2 cm. Soil moisture after sieving was equivalent to 40.8% WHCmax. One day after preparation, soil portions were weighed into the incubation flasks, adjusted to 55% WHCmax and pre-incubated at about 20 ± 2°C until application, i.e. for approx. 7 days.

Maximum Water Holding Capacity [WHCmax]	67.0 g/100 g
Bulk Density (disturbed)	1.07 g/cm3

Methods

1. Experimental conditions: The study was performed in static incubation test systems under aerobic followed by anaerobic conditions in the dark at 19.9 ± 0.1 °C. The test system consisted of Erlenmeyer flasks (300 mL) attached, first with a trap attachment (permeable for oxygen) containing soda lime for absorption of $^{14}CO_2$ and a polyurethane foam plug for adsorption of volatile organic compounds, second with a gastight gas sampling bag. Aliquots of 100 g of dry soil were weighed into the test flasks. Replicates were set up and processed for each sampling (3 sampling dates including time 0 for the aerobic phase, 9 sampling dates including time 0 for the anaerobic phase). Additional flasks were used for determination of the microbial biomass. The final soil moisture, for the aerobic phase was adjusted to 55% of WHC_{max} by adding pure water.

The switch to anaerobic (flooded) conditions was made 30 days after test item application: The trap system of all remaining test flasks was removed and stored for later analysis. The soil of each flask was flooded with 150 mL of oxygen-depleted de-ionized water leading to a water layer of approx. 3 cm above soil level. The flasks were then equipped with sealable double-valve glass stoppers. The flasks were connected to plastic gas sampling bags, which had been flushed with nitrogen gas. The valves were set to connect flask headspace and gas sampling bag, but closing the system from the outer atmosphere. Such setup allowed for pressure-less closed-flask incubation. To ensure maintenance of fully oxygen-free conditions, the test systems furthermore were placed in an argon, then nitrogen flooded box within the incubation chamber.

2. Test Item Stock Solution: The entire delivered amount of [^{14}C] BYI 02960 was dissolved in 4 mL methanol.

3. Test Item Application Solution: An application solution was made by diluting 2-3-mL aliquots of stock solutions in 20 mL of purified water.

4. Mode of Application: The test systems were removed from the incubation chamber and dosed with 447 µL, 549 µL or 464 µL of respective application solutions per flask. Treatment was made as small droplets applied directly onto the soil surface using a micropipette. Each flask was then gently shaken to incorporate the radiochemical into the test soil. Care was taken not to form clumps during the mixing process. Finally, the test systems were fitted with the volatiles traps and placed back into the

incubation chamber. Biomass and anaerobic bacteria determination test systems were either left untreated (native soil sample DAT-0), or dosed with 30 µL of methanol.

The test vessels for DAT-0 were immediately processed for analysis. All other test vessels, including the biomass flasks which were not spiked with application solution, were fitted with trap attachments and incubated in the dark at nominal 20 ± 2°C.

[PYR-^{14}C] BYI 02960 was applied at a rate of 494,261.3 Bq per vessel. This corresponds to 110.1 µg per vessel which is equivalent to 102.3 % of the intended field application rate of 106.7 µg per vessel (calculated an application rate of 400 g BYI 02960 per hectare). [FUR-^{14}C] BYI 02960 was applied at a rate of 412,122.5 Bq per vessel, this corresponds to 104.6 µg per vessel which is equivalent to 98.0 % of the intended application rate. [ETH-^{14}C] BYI 02960 was applied at a rate of 416,163.9 Bq per vessel. This corresponds to 105.9 µg per vessel which is equivalent to 99.2 % of the intended application rate.

5. Sampling: Characterization of the soil microbial viability was achieved by (a) determinations of soil microbial biomass during the aerobic incubation phase, and (b) by determinations of anaerobic bacteria during the anaerobic incubation phase. Biomass measurements were conducted at the beginning of the incubation period (DAT-0) for a pre-equilibrated but untreated test system, and at the end of aerobic incubation period (DAT-30) for a test system treated with a test item and a test system treated with the application solvent (30 µL of methanol). Determinations of anaerobic bacteria were performed at the end of the study (DASF-123) for an untreated test system and a test system treated with the application solvent, each. For procedure descriptions see Sections 3.6.2.7 and 3.6.2.8 of report.

Entire test flasks were taken for processing and analysis at 0, 23 and 30 days after treatment (DAT, (i.e. the aerobic phase) and 0, 1, 4, 7, 14, 29, 60, 90 and 123 days after soil flooding (DASF).

Aerobic systems: After collection of the respective test systems from the incubation chamber, samples taken on days 23 and 30 were exposed to vacuum for about 10 min to purge the volatiles possibly still present in the headspace into the traps. Then, the flask and volatile traps were separated. For the samples which were directly processed after application (DAT-0), no volatiles were collected.
At each sampling date the entire amount of soil in each test vessel was transferred into a centrifuge beaker and extracted using a mechanical shaker.

Anaerobic systems: After collection of the respective test systems from the incubation box, they were connected to a volatiles combustion oven unit. Using nitrogen, volatiles present in the headspace and gas sampling bag were slowly purged over a soda lime trap for absorption of $^{14}CO_2$, through the catalytic oven for oxidative combustion of organic volatiles (e.g. methane), and finally through three liquid scintillation flasks filled with LSC cocktail, in order to absorb $^{14}CO_2$ contained in the combustion exhaust. LSC cocktail traps were directly analyzed.

Next, the test flasks were opened, and the oxygen content of the water layers as well as the redox potential and the pH value of the water phases and soils layer were immediately determined by electrode measurements.

The water layers were separated from the soil layers by decanting. For removal of suspended particles, the decanted water layers were centrifuged for about 20 min at ca. 10000xg and filtered through a paper filter. The supernatants were analyzed without further extraction. The centrifugation pellets were added to the soil phases, by re-use of the centrifuge flasks for the extraction of the respective soil layers.

Soil extracts and decanted water layers were subjected to chromatography profiling within a maximum of 2 days after sampling. Samples were stored in a refrigerator prior to analysis. After analysis, they were stored deep frozen at about -20°C. Extracted soil was air-dried at room temperature. Combustion analysis was conducted within a maximum of 127 days. Absence of losses upon storage can be concluded from the complete radioactive material balances. After analysis, the soil samples were stored deep frozen at about -20°C. Volatiles traps were processed and analyzed within a maximum of 35 days. Sample stability can be concluded from the complete radioactive material balances.

6. Description of analytical procedures: The soil processing procedure was optimized to obtain >90% extraction efficiency and >90% recovery of the test item at time zero. Extraction was by cycles of heavily shaking for about 30 minutes on a mechanical shaker at room temperature followed by centrifugation (ca. 10 min, 10000xg) and decanting through a paper filter. At each sampling date, the soil samples were extracted with 3 x 80 mL acetonitrile/water (80/20, v/v) and 1 x 80 mL acetonitrile by shaking at ambient temperature. A further extraction step followed with acetonitrile/water (80/20, v/v) at 70°C using a microwave for 10 minutes. 'Ambient' and 'aggressive' extracts were kept separate for individual chromatography profiling.

The BYI 02960 residues and transformation products were analyzed and quantified by LSC and reversed phase radio-HPLC. Losses of radioactivity after concentration of extracts were minimal. Normal-phase Si-60 radio-TLC was used as a confirmatory method. The identity of the test item in stock solution and in extracts was confirmed by spectroscopic methods. In addition, spectroscopic methods were used to identify one of the minor metabolites.

The disappearance kinetics of BYI 02960 in the entire test systems during the anaerobic phase was individually calculated for each radiolabel. The calculation was done according to FOCUS kinetics guidelines.

Results and discussion

Results indicated that anticipated standardized conditions were maintained, and the soils were microbial active throughout the entire laboratory study, i.e. in the aerobic as well as the anaerobic phase where anaerobic bacteria plate count assays showed the presence of at least 33000 colony forming units per gram of soil dry weight for untreated soil or soil treated with application solvent. This confirmed the establishment of an anaerobic micro flora in the test systems.

Oxygen content in the water layer was below 1 mg/L 4 days after soil flooding (DASF) for all three labels. Throughout the rest of the anaerobic incubation phase oxygen concentration stayed below this value. Redox potential measurements indicated transition of the system to reducing conditions, in both soil and water layer from DASF-29 or DASF-60 onwards. The pH values scatter until DASF-29. Afterwards, they increased slightly (from about pH 6.8 to pH 7.3/7.4) and approached a plateau at around DASF-60. The pH values in the sediment were slightly lower than the pH-values in the water layers (see Table B.8.1.1.2-02 to Table B.8.1.1.2-04).

Data

The respective data for the three different radiolabels are shown in Table B.8.1.1.2-05 to Table B.8.1.1.2-07. The DAT-0 extraction efficiency was 95.4, 96.7 and 95.2% of AR (sum of ambient and aggressive extract), and for labels PYR, FUR and ETH, respectively. The stability of BYI 02960 during processing was verified by mean purities >98.1, >98.2 and >98.2% in the ambient extracts and 100% in the aggressive extracts of labels PYR, FUR and ETH, respectively. These results indicate that the extraction method was well suited to extract the applied [^{14}C]-labeled test item from the soil matrix.

Mass Balance

Material balance ranged from 93.4 to 98.1% (PYR), 94.1 – 99.7% (FUR) and 95.7 – 99.4% (ETH) of the applied radioactivity [AR]. The high material balances shown for all sampling intervals demonstrate that no significant RA dissipated from the flasks or was lost during processing.

Table B.8.1.1.2-08 Synopsis mass balance and recovery of radioactivity

Label	PYR	FUR	ETH
Total Recovery (%)	93.4 – 98.1	94.1 – 99.7	95.7 – 99.4
Extracted RA (%)	41.5 – 95.4	40.2 – 96.7	52.0 - 95.2
Max. Volatile RA (CO_2) (%)	26.7	15.9	6.9
Bound Residues (%)	2.7 – 17.8	3.1 - 30.1	2.8 - 15.2
Extraction Efficiency on DAT-0 (%)	95.4	96.7	95.2

Extractable and Bound Residues (NER)

Extractable ^{14}C-residues (plus the portions in the water layer after flooding) decreased from 95.4, 96.7 and 95.2% of AR at DAT-0 to 50.5, 48.9 and 76.1% of AR at study end (DASF-123) for labels PYR, FUR and ETH, respectively.

Non-extractable ^{14}C-residues increased from 2.7, 3.1 and 2.8% of AR at DAT-0 to max. 17.8% (PYR), 30.1% (FUR) and 15.2% (ETH) of AR at DASF-90, respectively, a slight decrease was observed at the final sampling point.

Volatilization

^{14}C-carbon dioxide accounted for up to 26.7, 15.9 and 6.9% of AR at maximum for labels PYR, FUR and ETH, respectively. Mineralization occurred during the 30 days of aerobic incubation, during the anaerobic phase after 30 days the percentages of BYI 02960 in the entire systems decreased from 94.5, 95.1 and 93.5% of AR to 53.7, 52.6 and 54.7% of AR for labels PYR, FUR and ETH, respectively. During the anaerobic incubation period (i.e. flooded state) the portions of BYI 02960 decreased further to 47.8, 47.2 and 47.7% of AR for labels PYR, FUR and ETH, respectively.

Transformation of Test Item

In the course of the study several transformation products were detected and quantified (see Table B.8.1.1.2-05 to Table B.8.1.1.2-07). Up to five minor transformation products were detected in the test systems of label PYR, and up to four minor transformation products were detected in the test systems of label FUR. In the test systems of label ETH, two transformation products were detected. One of these was identified as difluoroacetic acid (DFA) by HPLC-MS with accurate mass detection. During the aerobic incubation phase, the amounts of DFA increased up to 25.1% of AR at DAT-30. During the anaerobic phase, the amounts of DFA remained more or less constant (24.2 - 26.2% of AR). The second, minor, transformation product (ROI Z) appeared from DAT-30 onwards in amounts ranging from 0.7 - 1.3% of AR.

The results did not change the proposed overall pathway of degradation of BYI 02960 in soil shown in Figure B.8.1.3-01.

Kinetics of Test Item Degradation

A summary of the DT_{50} and DT_{90} calculation for the test item is given in Table B.8.1.1.2-09 (including the data for alternate kinetic model evaluations). The single first order model (SFO) was chosen as the best fit kinetic model for all labels (indicated bold typed in Table B.8.1.1.2-09).

Overall, the amount of BYI 02960 was declined very slowly during the test period of 123 days. The estimated DT_{50} values range from 581.8 to 693.2 days (geometric mean: 633.7 days).

Table B.8.1.1.2-09 Summary of the kinetic evaluation (according to FOCUS) of the degradation of [14C] BYI 02960 in Anaerobic Soil at 20 °C

		Parent BYI 02960

Conclusions

Major Outcomes of Study

The data gathered in the laboratory investigation demonstrate that residues of BYI 02960 are degraded very slowly in silt loam HF under anaerobic conditions at 20°C without the formation of further metabolites. For parent compound a SFO geometric mean DT_{50} value of 633.7 days was calculated. Observed portions of $^{14}CO_2$, NER and one major metabolite (DFA) were formed during the 30 days of aerobic incubation phase. A synopsis of results is shown in Table B.8.1.1.2-10.

Significance of Results to Environmental Behavior of BYI 02960

Based on the results obtained within this study it can be expected that the amounts of BYI 02960 and its only major metabolite DFA remain stable under flooded field conditions.

Degradation would be expected to continue according to the proposed overall pathway of degradation of BYI 02960 (see Figure B.8.1.3-01) whenever the conditions in soil turn aerobic again.

Summary

The anaerobic biotransformation of [pyridine-2,6-^{14}C] BYI 02960 was studied in a loamy sand (pH 6.7 in 0.01M CaCl2, organic carbon 0.45%) from Sanger, California, USA. During the first phase of the study, the soil was maintained under aerobic conditions for 30 days in the dark at 20 ± 1 °C and at soil moisture of 55% maximum water holding capacity. Following the aerobic phase, the samples were flooded with water (water:soil ratio 3:1, w/w) and maintained in the dark under anaerobic conditions for 121 days at 20 ± 1 °C. [PYR-^{14}C] BYI 02960 was applied at a rate of 1.17 µg a.i./g, dry soil, equivalent to an application rate of 410 g a.i./ha.

Samples were analyzed at 0, 14 and 32 days of aerobic incubation, and at 0, 14, 30, 45, 59, 91 and 121 days of incubation following flooding (post treatment) of the samples (anaerobic phase). The water was decanted from each test system and the soil was extracted by a shaking method. In addition, aggressive extraction was conducted. The water layer, ambient extract and the microwave extracts were analyzed by HPLC. Identification of the parent compound and major metabolite was achieved by mass spectrometry (LC/ESI/MS) and co-chromatography using an authentic standard.

The average total material balance in the soil/water system for BYI 02960 was 96.5% ± 1.8% of AR. Non-extractable (bound) residues in soil increased from 0.6% at day 0 to 15.7% at day 32. At the end of the aerobic phase, 6.1% of the applied radioactivity was present as CO_2. No volatile organic compounds were present. The concentration of BYI 02960 in the aerobic phase decreased to 61.4% of AR at day 32.

In the anaerobic phase, radioactivity in the combined water and ambient extract decreased from 60.2% at day 0 to 35.8% by the end of the study. Aggressive extractions with both acetonitrile:water and methanol:water ranged from 3.1% to 2.9% of the applied radioactivity in the study, indicating that residue left after ambient and aggressive extraction was not easily extractable. Since non-extractable residues did not change during aerobic (15.7%) and anaerobic phases (16.1%), no further characterization was conducted. No CO_2 or volatile organic compounds were produced during the anaerobic phase of the study.

During the anaerobic phase, the concentration of BYI 02960 in soil decreased from 51.1% at day 0 to 26.2% of the applied amount at study termination. One major metabolite, 6-chloronicotinic acid (6-CNA), was detected during the aerobic phase of the study and it reached maximum of 12% (water/sediment) at day 0 of anaerobic phase and remained steady (12 to 14 %) throughout anaerobic phase. One minor metabolite, BYI 02960-chloro was detected during the aerobic phase and accounted for 2.8% at day 32. During the anaerobic phase, it remained steady (2%).

The observed DT_{50} values for BYI 02960 in the aerobic, then anaerobic soil/water system were determined using single first-order kinetics (SFO), first-order multi compartmental (DFOP) and double

first-order in parallel (FOMC) and half-lives were 152 days, 164 days and 584 days, respectively for the anaerobic phase. BYI 02960 degrades moderately under aerobic conditions and remains more or less stable during anaerobic phase in soil.

Materials and methods

Materials

1. Test Item: [Pyridine-2,6-^{14}C] BYI 02960 (Flupyradifurone) (sample IDC-1135A); Specific activity: 35.03 mCi/mMole; Radiochemical purity: 99; Identity and purity of test item in the application solution was confirmed.

2. Soil The biotransformation of BYI 2960 was studied in one soil. The soil was taken from Sanger, California, USA and transported by air to Stilwell, KS at ambient temperature. It was stored for 13 days at 4 °C prior to use. The soil was sieved through a 2 mm sieve. Soil moisture was adjusted to 50% WHCmax and pre-incubated at about 20 ± 2°C until application, i.e. for approx. 20 days.

Methods

1. Experimental conditions: The study was performed in flow-through incubation test systems under aerobic, and later under static anaerobic conditions in the dark at 20 ± 0.1 °C. During the aerobic phase, the test system consisted of Erlenmeyer flasks (250 mL) with a trap attached for absorption of ^{14}C-volatiles and $^{14}CO_2$, consisting of ethylene-glycol, potassium hydroxide and sulfuric acid,

respectively. During the anaerobic phase, test systems were flooded with nitrogen to purge oxygen from the systems. Aliquots of 50 g of dry soil were weighed into the test flasks. Replicates were set up and processed for each sampling. The final soil moisture was adjusted to 55% of WHC_{max} by adding pure water. The switch to anaerobic (flooded) conditions was made 30 days after test item application: The trap system of all remaining test flasks was removed and stored for later analysis.

2. Test Item Application Solution: [Pyridine 2,6-^{14}C] BYI 02960 was mixed into an aliquot of 1.3 mL acetonitrile dissolved 8.5 mL methanol:water (1:1).

3. Mode of Application: The application solution was applied at 200 µL evenly across the soil surface with a 250 µL syringe. The flasks were gently rotated to mix the treated soil, connected to volatile traps and kept at 20 C in the environmental chamber. [PYR-^{14}C] BYI 02960 was applied at a rate of 15,922,150 dpm per vessel. This corresponds to 58.4 µg per vessel.

4. Sampling: Duplicate test systems were sampled at day 0, 14 and 32 under aerobic conditions and after the 30 day aerobic incubation period, duplicate anaerobic test systems were analyzed at 0, 14, 45, 59, 91 and 121 days. During the anaerobic phase, pH, redox potential and dissolved oxygen were measured.

During the aerobic phase on the day of sampling, test systems were removed from the incubator along with the attached traps for the volatile and CO_2 analysis. During the anaerobic phase, volatile traps were attached and nitrogen was purged through the head space to trap any volatiles.

Samples were processed and soil was extracted on the day of sampling. The water was decanted from each test system and the soil was extracted by a shaking method. Water and extracts were analyzed with 10 days after sampling.

5. Description of analytical procedures: Extraction was done by cycles of heavily shaking for about 30 minutes on a mechanical shaker at room temperature followed by centrifugation (ca. 5 min, 2100g) and filtering through a paper filter. The soil samples were extracted with 3 x 150 mL acetonitrile/water (70/30, v/v) and 1 x 150 mL acetonitrile by shaking at ambient temperature. A further extraction step followed with acetonitrile/water (70/30, v/v) at 70°C using a microwave for 10 minutes. An aliquot of the combined 'ambient' and 'aggressive' extracts was transferred to a flask and rotovapped at 30°C.

The extracted soil was air dried and subsamples were combusted to quantify the non-extractable residues (NER). The water layer, ambient extract and the microwave extracts were analyzed by LSC and HPLC using a flow-through ^{14}C detector. Identification of the parent compound and major metabolite was achieved by mass spectrometry (LC/ESI/MS) and co-chromatography using an authentic standard.

Results and discussion

Results indicated that anticipated standardized conditions were maintained, and the soils were microbial active over the duration of the laboratory study.

Table B.8.1.1.2-12 Dissolved oxygen, pH and redox potential of the test systems of the [PYR 2,6-^{14}C] BYI 02960 anaerobic soil metabolism study (mean of duplicates)

Measurement Interval [Days of post flooding]	Dissolved Oxygen (mg/L)	pH	Redox (E_o) in Water (mV)	Redox (E_h) in Water (mV)	Redox (E_o) in Soil (mV)	Redox (E_h) in Soil (mV)

121	0.4	7.1	-70.9	126.2	-128.1	69.0

NA = not analyzed, $E_h = E_{Obs} + E_{Ref}$
Where: E_h = Redox potential referred to the hydrogen scale
E_{Obs} = Observed redox potential of electrode (Ag/AgCl)
E_{Ref} = Redox potential of the electrode as related to the hydrogen electrode (Ag/AgCl = +197 mV)

Data

Data on biotransformation is shown in Table B.8.1.1.2-13. The DAT 0 extraction efficiency was 99.4% of AR. The aggressive extraction removed approximately 2% to 3% radioactive residues during the study. These results indicate that the extraction procedure was efficient in extracting the majority of radioactive residues from the soil. At the end, bound residue was 16.1% of applied.

Table B.8.1.1.2-13 Biotransformation of [PYR-^{14}C] BYI 02960 in silt loam under aerobic, then anaerobic conditions; mean values and SD expressed as % of AR)

Mass Balance

The average material balance was 96.5% ± 1.8% (mean range = 93.8% to 100%)

Extractable and Bound Residues (NER)

In the aerobic phase, extractable ^{14}C-residues in soil decreased from 99.4% at day 0 to 75.3% at day 32. Bound residues increased from 0.6% at day 0 to 15.7% at day 32.

In the anaerobic phase extractable ^{14}C-residues in soil decreased from 60.2% at day 0 to 35.8% at day 121. In the water layer, ^{14}C-residues increased from 16.7% at day 0 to 38% at the end of the study. Bound residues reached a maximum of 18.7% at day 59 and declined slightly to 16.1% at day 121 post-flooding.

Volatilization

At the end of the aerobic and anaerobic phase 6.1 and 6.0% of AR were present as CO_2. No organic volatiles were detected.

Transformation of Test Item

Within the aerobic phase of the study (30 days) the percentages of BYI 02960 in soil decreased from 98.5% (day 0) to 61.4% of AR (day 32). The major metabolite 6-chloronicotinic acid (6-CNA) increased from 0.9 to 11.1% of AR. During the anaerobic phase, the concentration of BYI 02960 in water and soil decreased from 62.7% (day 0) to 48.9% of AR at the end of the study. The proportion of metabolite 6-CNA was more or less constant during the anaerobic phase (12.4% at day 121).

The minor metabolite BYI 02960-chloro was observed at day 14 of the aerobic phase, reaching a maximum of 2.8% on day 32. During the anaerobic phase, it remained between 2% and 3%.

Further, there was a diffuse area of radioactivity, consisting of multiple peaks, which reached a maximum of 8.7%. None of the peaks accounted for more than 3.1% of applied. The proposed degradation pathway is depicted in Figure B.8.1.3-01.

Kinetics of Test Item Degradation

A summary of the SFO DT_{50} and DT_{90} calculation for the test item is given in Table B.8.1.1.2-14. The degradation may be due to residual aerobic conditions following flooding and should not be considered anaerobic soil degradation, anaerobic conditions were achieved after 14 days post flooding. The calculated half-life values should be attributed to the initial aerobic conditions with the test systems and not anaerobic soil half-life.

Conclusions

Major Outcomes of Study

BYI 02960 degraded under aerobic/anaerobic conditions. Most of the degradation occurred during the aerobic phase and once anaerobic conditions were established, very little degradation occurred. During the aerobic phase, 6-CNA was the major metabolite formed and it remained more or less constant during the anaerobic phase (between 11 and 14% of AR), assuming that it needed further days post flooding until strictly anaerobic conditions were achieved. A minor degradate, BYI 02960-chloro, accounted for 2.8% at day 32 of the aerobic phase and remained more or less constant during the anaerobic phase, too. A synopsis of results is shown in Table B.8.1.1.2-14.

Significance of Results to Environmental Behavior of BYI 02960

BYI 02960 degrades under aerobic condition; however, once anaerobic conditions are reached its residues remain more or less stable in soil.

Summary

The anaerobic biotransformation of [pyridine-2,6-^{14}C] BYI 02960 was studied in sandy clay loam (pH 6.5 in 0.01 M $CaCl_2$, organic carbon 1.9%) from Springfield, NE, USA. During the first phase of the study, the soil was maintained under aerobic conditions for 29 days in the dark at 20 ± 2°C and at soil moisture of 55% maximum water holding capacity. Following the aerobic phase, the samples were flooded with water (water:soil ratio 3:1, w/w) and maintained in the dark under anaerobic conditions for 60 days at 20 ± 2 °C. The study was terminated after the 60 day sampling due to a failure of: the temperature control which resulted in a temperature of 50°C and compromised the remaining samples. [PYR-^{14}C] BYI 02960 was applied at a rate of 1.1 µg a.i./g, dry soil, equivalent to an application rate of 410 g a.i./ha.

Samples were analyzed at 0, 14 and 29 days of aerobic incubation, and at 0, 19, 31, 45 and 60 days of incubation following flooding (post treatment) of the samples (anaerobic phase). The water was decanted from each test system and the soil was extracted using a shaking method. In addition, an aggressive extraction was conducted. The water layer, ambient extract and the microwave extracts were analyzed by HPLC using a flow-through 14C detector. Identification of the parent compound was achieved by mass spectrometry (LC/ESI/MS) and co-chromatography using an authentic standard.

The material balance for the study was complete (on average 105.8% ± 3.2%, mean range = 100.0 to 109.4%). Extractable [^{14}C] residues in soil decreased from 99.7% at day 0 to 79.0% by day 29. Non-extractable (bound) residues in soil increased from 0.3% at day 0 to 9.8% at day 29. At the end of the aerobic phase, 16.2% of the applied radioactivity was present as CO_2. No volatile organic compounds were present. In the aerobic phase the concentration of BYI 02960 decreased from 99.7% of the applied amount at day 0 to 79.0% at day 29. In the anaerobic phase, radioactivity in the combined ambient and aggressive extracts remained steady from 69.5% at day 0 to 71.7% by the end of the

study. Aggressive extractions ranged from 6.7% to 11.7% of the applied radioactivity in the study, indicating that residue left after ambient and aggressive extraction was not easily extractable. NER and CO_2 in soil remained more or less constant during the anaerobic phase of the study, and no volatile organic compounds were produced.

BYI 02960 degrades moderately under aerobic conditions and its residues remain more or less stable during anaerobic phase in soil.

The study was terminated after the 60 day sampling due to a failure of the temperature control which resulted in a temperature of 50°C and compromised the remaining samples, this does not affect the interpretation of results of the study.

Materials and methods

Materials

1. Test Item: [Pyridine-2,6-^{14}C] BYI 02960 (Flupyradifurone) (sample IDC-1135A);Specific activity: 35.03 mCi/mMole; Radiochemical purity: 100%; Identity and purity of test item in the application solution was confirmed.

2. Soil: The test matrix used in this study was sandy clay loam from Springfield, Nebraska, USA. This site had no prior history of pesticide application for 5 years. The soil was transported from Nebraska to the testing facility, KS, by air cargo at ambient temperature, and upon arrival at Bayer CropScience, Stilwell, KS, was stored in a refrigerator at 4 ºC. Prior to the use, the soil was maintained at an average temperature of 4°C at the testing facility for 6 days. Soil was sieved through a 2-mm sieve. Soil was acclimated for a period of 6 days before treatment. Moisture was not adjusted due to no significant moisture loss from the time the test systems were set up until the time of flooding.

Table B.8.1.1.2-16 Soil physicochemical properties

Parameter	Results/Units
Geographic Location (City / State / Country)	Springfield / Nebraska, USA
GPS coordinates of sampling site	96.15085 41.03725
Taxonomic Name	Fine, kaolinitic, thermic Typic Kanhapludults
USDA Texture Class	Sandy clay loam
Sand / Silt / Clay (%)	53.1 / 23.2 /23.7
pH (soil/water, 1/1) pH (Saturated Paste) pH (soil/0.01 M $CaCl_2$ 1:2)	6.7 6.6 6.5
Organic Matter	3.3%
Organic Carbon	1.9%
Initial soil biomass (Day 0 aerobic)	263 mg microbial C/kg soil
Soil biomass on flooding day (Day 0 anaerobic)	433 mg microbial C/kg soil (untreated control soil)

Biomass at the end of the study (anaerobic)	Since the study was terminated due to the increased temperature from a malfunctioning incubator (>50 °C), biomass determination was not assessed as the biological component may have been compromised from the higher temperature
Cation Exchange Capacity (CEC)	17.6 meq/100 g
Maximum Water Holding Capacity	61.4%
Bulk Density (disturbed)	1.03 g/cm^3

Methods

1. Experimental Conditions: The study was performed under static aerobic incubation conditions, and later under flow-through anaerobic incubation conditions in the dark at 20 ± 0.1 °C. The test system consisted of 250-mL Pyrex® Erlenmeyer flasks (containing 50 g soil (dry weight)) with side arms for attachment to traps for the collection of CO_2 and volatile organic compounds. During the aerobic phase, test systems were kept in an environmental chamber at 20 ± 2 °C. The final soil moisture was adjusted to 55% of WHC_{max}. During the anaerobic (flooded) phase, they were kept in a temperature-controlled incubator with a nitrogen-filled atmosphere at 20 ± 2 °C. During incubation, aluminum foil was wrapped around flasks to prevent exposure to light.

The switch to anaerobic (flooded) conditions was made 29 days after test item application. The trap system of all remaining test flasks was removed and stored for later analysis.

2. Test Item Application Solution: [Pyridine 2,6-^{14}C] BYI 02960 (vial no. C-1135A) was mixed into an aliquot of 1.3 mL acetonitrile dissolved 8.5 mL methanol:water (1:1). The solution was mixed using a vortex and sonicator to get a homogeneous solution.

3. Mode and Rate of Application: The application solution (200 µL) was applied evenly across the surface of the soil using a 250-µL syringe. After treatment, 9 mL of water was added to the flasks to bring soil moisture to ~ 55% of max water holding capacity (MWHC). The flasks were gently rotated to mix the treated soil. The flasks were labeled, wrapped in aluminum foil and weighed. Flasks were connected to volatile traps and kept at 20 ± 2 °C in the environmental chamber.
[PYR-^{14}C] BYI 02960 was applied at a rate of 15,122,786 dpm per vessel. This corresponds to 56.1 µg per vessel. Material balances for the kinetic treatment test systems of the study were based on the theoretical dpm applied to the soil.

4. Sampling: Duplicate test systems at day 0, 14 and day 29 were analyzed under aerobic conditions. After the 29-day aerobic incubation, duplicate anaerobic test systems were analyzed at 0, 19, 31, 45 and 60-days post-flooding intervals. During the anaerobic phase of the study, test systems were measured for pH, redox potential, and dissolved oxygen. Radioactive CO_2 and volatile organics were measured at each interval. The water was separated from the soil by decanting.

Samples were processed and soil was extracted on the day of sampling. Water and extracts were analyzed within 7 days of sampling. The extracts and water were stored in a laboratory refrigerator.

The concentrated extracts were stored in the laboratory freezer until analysis, and were moved to a central freezer for long-term storage.

During the aerobic phase on the day of sampling, test systems were removed from the incubator along with the attached traps for the volatile and CO_2 analysis. During the anaerobic phase test systems were removed from the incubator, volatile traps were attached and nitrogen was purged through the head space to trap any volatiles from the head space into the bubblers.
5. Description of Analytical Procedures: The volatile organics were collected from the headspace of the treated test systems using 2 M KOH, ethylene glycol, and 1 M H_2SO_4. The trapping solutions were radioassayed in triplicate 1-mL aliquots for KOH, ethylene glycol and H_2SO_4. The aqueous portion of the sample was filtered through a Whatman GF/F glass filter into a 250-mL graduated cylinder. The water was radioassayed in triplicate 1-mL aliquots by LSC.

The soil was transferred to a 250-mL bottle, and 40 mL of acetonitrile/water (70/30) was added to the bottle which was then extracted on a bench-top shaker for 30 minutes. The samples were centrifuged for 5 minutes at 1850 g. The extracts were filtered through a Whatman GF/F filter into a 250-mL graduated cylinder. The extraction procedure was repeated two additional times with acetonitrile/water (70/30) and another time with 100% acetonitrile. The combined aqueous portion (ambient extract) was radioassayed in triplicate 1-mL aliquots. A further extraction step followed once with 50 mL of acetonitrile/water (70/30) and once with 50 mL of methanol/water (50/50) at 70°C using a microwave for 10 minutes (650 Watts). After the acetonitrile/water (70/30) microwave extraction the sample was centrifuged for 5 minutes at 1850 g and decanted through a Whatman GF/F filter into a 250-mL graduated cylinder. Following the methanol/water (50/50) microwave extraction the entire sample were filtered through a Whatman GF/F filter into the same 250-mL graduated cylinder and aliquots (3 x 1-mL) were radioassayed. The remaining soil was allowed to air dry on the filter.

The extracted soil samples were air dried, homogenized thoroughly and weighed. Subsamples (approximately 0.5 g) of the soil were combusted to quantify the non-extractable residue (NER).

The water layer, ambient extract and the microwave extracts were analyzed by LSC and HPLC using a flow-through ^{14}C detector. Identification of the parent compound and major metabolite was achieved by mass spectrometry (LC/ESI/MS) and co-chromatography using an authentic standard.

Results and discussion

Results indicated that anticipated standardized conditions were maintained, and the soils were microbial active over the duration of the laboratory study.

Table B.8.1.1.2-17 Dissolved oxygen, pH and redox potential of the test systems of the [PYR 2,6-^{14}C] BYI 02960 anaerobic soil metabolism study (mean of duplicates)

Measurement Interval [Days of post flooding]	Dissolved Oxygen (mg/L)	pH	Redox (E_o) in Water (mV)	Redox (E_o) in Soil (mV)
0	4.52	6.13	250.7	264.8
19	0.45	6.64	150.2	182.1
33	0.30	6.69	-10.6	20.9
45	0.26	7.04	-64.6	-46.1
60	0.03	6.98	-152.1	-128.9

NA = not analyzed, $E_h = E_{Obs} + E_{Ref}$
Where: E_h = Redox potential referred to the hydrogen scale
E_{Obs} = Observed redox potential of electrode (Ag/AgCl)
E_{Ref} = Redox potential of the electrode as related to the hydrogen electrode (Ag/AgCl = +197 mV)

Data

Data on biotransformation is shown in Table 8.1.1.2-18. The DAT 0 extraction efficiency was 99.7% of applied radioactivity. The shake procedure extracted an average of 99.7% of the applied radioactivity at aerobic day 0. This indicated that the extraction procedure was efficient in extracting the majority of the radioactive residues from the soil, and did not degrade the parent. The bound residue at the end of the study was 12.9% of the applied radioactivity.

Mass Balance

The average material balance for the study was 105.8 ± 3.2% (mean range = 100.0 to 109.5%).

Extractable and Bound Residues (NER)

In the aerobic phase, extractable [^{14}C]residues in soil decreased from 99.7% at day 0 to 79.0% by day 29. Non-extractable (bound) residues in the soil increased from 0.3% at day 0 to 9.8% at day 29.

In the anaerobic phase, extractable [^{14}C]residues in soil remained constant with residues from 69.5% at day 0 to 71.7% at day 60. In the water layer [^{14}C]residues also remained constant from 7.7% at day 0 to 6.3% at the end of the study. Non-extractable residues in soil reached a maximum of 14.8% at day 19 and declined to 12.9% at day 60, post flooding.

Volatilization

At the end of the aerobic and anaerobic phase, 16.2 and 17.9% of the applied radioactivity was present as CO_2, and no organic volatile compounds were detected.

Transformation of Test Item

During the aerobic phase, the concentration of [PYR-^{14}C] BYI 02960 in the soil decreased from 99.7% at day 0 to 74.4% of the applied amount at day 29. Other unidentified radioactivity remained constant from aerobic day 14 until the end of the study, ranging from 4.6 to 6.4% of the applied amount of radioactivity. During the anaerobic phase, the concentration of BYI 02960 remained constant, starting at 71.9% on day 0 and ending at 72.5% at the termination of the study. Non-extractable residues were less than 20% of AR, therefore, no further fractionation was conducted.

Kinetics of Test Item Degradation

Following the flooding of the Springfield, NE, sandy clay loam test system, BYI 02960 levels remained stable through the end of the study. Since degradation of BYI 02960 did not occur during the anaerobic phase of the study, kinetic endpoints could not be derived.

Conclusions

Major Outcomes of Study

[PYR-^{14}C] BYI 02960 steadily degraded during the aerobic phase, but once the test systems were flooded with water, no further degradation of [PYR-^{14}C] BYI 02960 occurred during the anaerobic phase. Although the study was terminated after the 60 day sampling the results are consistent with those obtained with the other soils and labels.

Significance of Results to Environmental Behavior of BYI 02960

BYI 02960 degrades under aerobic conditions. Once anaerobic conditions are reached, BYI 02960 is stable. Thus, degradation will not be a major route of dissipation in a flooded anaerobic soil environment.

Remarks

The anaerobic soil degradation study is acceptable and the results are reliable, altough the study was terminated after 60 days due to a failure of the temperature control. The study did not complete the guidance subscribed 120 days, however the same trend was observed as in the other anaerobic degradation studies submitted. Limited degradation of the test substance was observered.

B.8.1.1.3 Soil Photolysis

STUDY IIA, 7.1.3/01

Characteristics

year of execution	:	2008-2009	incubation time	:	up to 8 days
GLP statement	:	yes	nominal concentration	:	40.8 µg / 3 g soil
guideline	:	SETAC (1995), EPA 161-3 draft OECD (TG 2002)	temperature	:	22°C
test substance	:	[pyridinylmethyl-^{14}C] BYI 02960 and [furanone-4-^{14}C] BYI 02960	light intensity	:	1082 W m^{-2} for label PYM and 1116 W m^{-2} for label FUR (Cut off < 290 nm)
purity	:	radiochemical purity > 99%	Conclusion	:	study results reliable
soil	:	loam, Guadalupe, California, USA	acceptability	:	**acceptable**

Summary

Phototransformation of [pyridinylmethyl-^{14}C]- and [furanone-4-^{14}C] BYI 02960 was studied on a loam soil from Guadalupe, California, USA at an application rate of about 400 g/ha. The study was conducted for a period of eight days at 20°C ± 1°C and at soil moisture of about 75% of 1/3-bar water holding capacity (humid test samples). In addition, photolysis was studied on air dried samples.

[PYM-^{14}C] and [FUR-^{14}C] BYI 02960 were directly applied to the surface of the soil aliquots at an initial concentration of about 40.8 µg/ 3 g soil. The treated samples were continuously exposed to artificial irradiation (xenon lamp with <290 nm cut-off filter, 1082 W m^{-2} for label PYM and 1116 W m^{-2} for label FUR). In addition, dark controls were set up. Test vessels were connected to traps for the collection of CO_2 and organic volatiles. Samples from humid test systems were taken in duplicate 0, 0.2, 1, 4, 5, 7, and 8 days after application for the determination of the parent compound and the transformation product residues. Samples from additional test systems containing air dried soil were only taken at the end of the study period. The soil was extracted at ambient temperature with 2 x acetonitrile/water (1/1, v/v), 1 x acetonitrile/water (8/2, v/v) and pure acetonitrile at ambient temperature (ambient extraction). Afterwards, the soil was extracted once with acetonitrile/water (8/2, v/v) at an elevated temperature of 70°C (aggressive extraction). The BYI 02960 residues were analyzed by reversed phase HPLC with radioactivity detection. Selected samples were additionally analyzed by TLC as a confirmatory method. Identification and confirmation of the parent compound was by HPLC-MS, HPLC-MS/MS and NMR (stock solution) or co-chromatography (selected extracts).

The mass balances were complete indicating that no losses occurred during exposure or processing of samples. The mass balances were 99.3 ± 1.2% and 99.4 ± 0.9% of the AR in the irradiated and dark

soil samples of label PYM, respectively. For label FUR, the corresponding mass balances were 99.5 ± 0.6% and 99.5 ± 0.8% of the AR.

Extractable residues for radiolabel PYM decreased from 99.7% of the AR at day 0 to 98.0% and 98.9% of the AR at the end of the study for irradiated and dark systems respectively. Extractable residues for radiolabel FUR decreased from 99.3% of the AR at day 0 to 96.9% and 99.4% of the AR at the end of the study for irradiated and dark systems respectively. For both radiolabels tested the amounts of non-extractable residues (NER) in the irradiated and dark samples were low during the entire study.

In the irradiated test systems, BYI 02960 decreased to 93.8 and 93.5% of the AR by the end of the study for PYM and FUR radiolabel, respectively. No major transformation product was detected in the soil extracts, very minor transformation products were observed. The amounts of $^{14}CO_2$ at study termination amounted to 0.1% and 2.2% of the AR for PYM and FUR test systems, respectively. Organic volatile formation was negligible throughout the study (≤ 0.1% of the AR).

In the dark PYM and FUR test systems, BYI 02960 decreased just to 98.4 and to 97.3% of the AR by the end of the study. No transformation products were detected. At study termination, the amounts of $^{14}CO_2$ were 0.1% of the AR for both labels. Organic volatile formation was negligible throughout the study (≤ 0.1% of the AR).

In order to test the effects of the dryness of soil, a supplementary test was performed. As degradation was generally low, no significant differences between humid and dry soil samples were observed.

Overall the degradation of BYI 02960 was very slow. The degradation in irradiated test systems was slightly less slow compared to the degradation observed in dark test systems. The experimental DT50 values of BYI 02960 in the irradiated samples were 99.6 days (PYM) and 109.3 days (FUR), showing a good comparability for the results obtained with the two labels. The corresponding experimental DT_{50} values of BYI 02960 in the dark controls were > 1000 days (PYM) and 419.2 days (FUR).

The results of this study indicate that phototransformation on soil is of minor importance for the degradation of BYI 02960 under outdoor conditions and no major phototransformation products are expected.

Materials and methods

Materials

1. Test Items: Flupyradifurone: Code = BYI 02960; Label PYM = [Pyridinylmethyl-^{14}C] BYI 02960 (sample ID: KATH 6703); Specific activity: 4.37 MBq/mgRadiochemical purity: >99% (acc. radio-HPLC) Label FUR = [Furanone-4-^{14}C] BYI 02960 (sample ID: KATH 6702); Specific activity: 3.94 MBq/mg

;Radiochemical purity: >99% (acc. radio-HPLC); Identity and purity of test items in the application solution were confirmed.

2. Soil: The biotransformation of BYI 2960 was studied in one soil. The soil was taken fresh from the field. At the test facility, the soil was air dried broken up for sieving. Then, the soil was successively sieved to ≤ 10, 5, 3.35 and 2 mm. The sieved soil was filled in a plastic bag and stored at 4-8°C until further use.

Soil mapping unit	Latitude N35° 01'05.6", Longitude W120° 36'10.1"

Methods

1. Preparation and application of the test item: The test systems for the kinetic photolysis test with humid soil consisted of 32 quartz glass vessels for each label (36-mm inner diameter, 35-mm height, base area 10.2 cm^2) each containing 3 g of soil (dry weight), providing about 3-mm soil depth. In addition, 4 vessels containing air dried soil were prepared for each label. A glass neck with ground joint (NS 10) was attached to the side of the wall. There, except for day 0) the flask is closed with a solid trap attachment, a small glass tube of 90 mm length and 12 mm inner diameter, in which volatile compounds were bound to soda lime and polyurethane foam. The trap is packed in the following sequence: PU-foam plug → quartz wool → 2 g soda lime → quartz wool → 0.5 g soda lime → quartz wool. Soil moisture was about 75% of 1/3-bar water holding capacity at the time of application. Moisture adjustment was performed on day 4 by replenishing the lost water with 0 to 50 µL of Milli-Q-water using a Hamilton injection device.

Duplicate treated test systems were analyzed at each sampling interval for both irradiated and dark test systems.

In addition to the main test with soil Guadalupe CA adjusted to a definitive moisture (75% of 1/3 bar moisture), a supplementary non kinetic experiment was conducted in order to assess the effect of dryness on phototransformation of BYI 02960. For this purpose, soil was air dried to a remaining soil

moisture of 0.04 g / 3 g dry soil (about 11% of 1/3 bar moisture). Application of the test items, maintenance procedures and sampling details of this test were in line with the main test, but samples were taken on the last sampling intervals only.

The test items [PYM -^{14}C] BYI 02960 and [FUR-^{14}C] BYI 02960 were dissolved in 5.0 mL Milli-Q-water/methanol (1/1, v/v). The purity of the ^{14}C-labeled test items was determined by HPLC, resulting in mean purities of 99.8% and 99.6% for PYM and FUR, respectively.

According to an intended application rate of 400 g/ha, 39.2 µL (PYM) and 37.9 µL (FUR) of application solution was pipetted into each incubation vessel. The solutions were applied evenly as drops across the surface of the soil. The soil was not mixed or agitated after application.

The material balance of the study for both dark and irradiated test systems was based on the average amount of radioactivity (RA) recovered with these measurements: 186,094 Bq or 42.58 µg BYI 02960 for PYM and 156,914 Bq or 39.83 µg BYI 02969 for FUR (per 3 g soil (dry weight)).

2. Irradiation and sampling: The photolysis vessels were placed in a Suntest CPS+ unit (Xenotest GmbH, Hanau, Germany) containing a xenon lamp simulating natural sunlight. The light emission was filtered with a 290 nm cut-off UV-filter, which eliminates all wavelengths <290 nm. The exposure time and intensity under experimental conditions can be related to natural solar radiation, e.g. of Houston (Texas; USA), Los Angeles (California; USA) or Tampa (Florida; USA), representing areas of high intensity of sunlight. For example the total radiant exposure representative of a summer day (July) at a horizontal plane is 26 MJ m^{-2} (at Los Angeles), 22 MJ m^{-2} (at Houston) or 23 MJ m^{-2} (at Tampa). For humid samples, two test systems for each label were processed for analysis immediately after the application on day 0 (0 h). Subsequently, duplicates of both irradiated and dark soil samples for each label were processed at 0.2, 1, 4, 5, 7, and 8 days post-application. Air dried samples were only processed and analyzed at day 8 after application.

Soil samples were extracted immediately on the day of sampling. Extracts were analyzed within three days of sample extraction and then stored in a freezer (-18°C or below). Samples for CO_2 and volatile organics were stored at ambient temperature (≤ 12 days) until processing for analysis.

Prior to opening a test vessel, volatile compounds possibly still present in the headspace were transferred into the trap attachment. For this purpose, the test vessels were placed in a desiccator for 15 min and the headspace was carefully purged through the trap.

3. Description of analytical procedures: Volatile organic compounds possibly contained in the PU foam plug were extracted with 5 mL of ethyl acetate. 500 µL aliquots of the extracts were analyzed by LSC in duplicate. The radioactivity (i.e. $^{14}CO_2$) absorbed by the soda lime was liberated with 18% aqueous HCl

and purged and absorbed in a series of three Zinsser vials each filled with 20-mL of ice-cooled scintillation cocktail intended for radio-assay by LSC.

The extraction of the soil samples was similar to the extraction procedure used in the aerobic soil degradation study. The total amount of soil of each vessel was transferred into a 40 mL Teflon® centrifuge beaker and extracted once with 8 mL acetonitrile/water (1/1, v/v) followed by 5 mL acetonitrile/water (1/1, v/v), 5 mL ACN/water (8/2, v/v) and 5 mL ACN. The extractions were performed at ambient temperature on a mechanical shaker for 30 min. Each extraction step was followed by centrifugation (15 min, 10 000 x g) and decanting of the supernatant. All ambient extracts were combined and the volume was determined. Aliquots thereof were analyzed by LSC and reversed phase HPLC with radioactivity detection. Extracts sampled on day 0, 4 and 8 were also analyzed by TLC. Afterwards, the soil was extracted once with acetonitrile/water (8/2, v/v) at an elevated temperature of 70°C (aggressive extraction). Identification and confirmation of the parent compound was done by HPLC-MS, HPLC-MS/MS and NMR (stock solution) or co-chromatography (selected extracts).

The extracted soil was air dried and the non-extractable Residues (NER) were quantified by combustion.

The limit of quantification (LOQ) was set to three times the maximum background radioactivity, i.e. about 1.5 Bq (0.34 ng/500 µL for label PYM and 0.38 ng/500 µL for label FUR). The lowest amount measured in ambient and aggressive organic extract samples was about 25 Bq/500 µL, i.e. 16.7 times higher than the LOQ. For CO_2 liberated from soda lime and organic volatiles extracted with ethylacetate the lowest radioactivity measured (after background subtraction) were 1.2 and 0.01 Bq, respectively. Although these values were lower than the LOQ they were evaluated, resulting in amounts of radioactivity < 0.1% of AR.

Results and discussion

Data

Data on phototransformation and dark controls is shown in Table B.8.1.1.3-02 and Table B.8.1.1.3-03.

Mass Balance

The material balances were shown to be complete. For irradiated test systems the overall mean (±RSD) was of 99.3 (±1.2) and 99.5 (±0.6) % for label PYM and FUR, respectively. For dark test systems the overall mean (±RSD) was of 99.4 (± 0.9) and 99.5 (± 0.8) % for label PYM and FUR, respectively.

Distribution and Composition of Residues

For irradiated test systems PYM and FUR, the extractable amounts of radioactivity were 99.7% and 99.3% of the AR at day 0 and 98.0% and 96.4% at day 8, respectively. The amounts of NER were 0.1% and 0.0% of the AR at day 0 and remained at very low levels of 0.8% and 0.9% of the AR at the end of the test. $^{14}CO_2$ formation increased up to 0.1% and 2.2% by day 8 for label PYM and FUR, respectively. Organic volatile formation was negligible throughout the study (<1%).

For dark test systems PYM and FUR, the extractable amounts of radioactivity were 99.7% and 99.3% of the AR at day 0 and 98.9% and 97.4% at day 8, respectively. NER were 0.1% and 0.0% of the AR at day 0 and remained at the very low levels of 1.0% and 0.9% of the AR at the end of the test, respectively. $^{14}CO_2$ formation increased up to 0.1% at day 8 for both labels. Organic volatile formation was negligible throughout the study (<1%).

In the irradiated PYM test systems, BYI 02960 decreased from an average of 99.3% of the AR at day 0 to 93.8% of the AR by the end of the study. No major transformation product was detected in the soil extracts. From day 4 onwards, minor transformation products were detected. The maximum amount of a single peak accounted for 1.8% of AR (day 7).

In the irradiated FUR test systems, BYI 02960 decreased from an average of 99.1% of the AR at day 0 to 93.5% of the AR by the end of the study. From day 1 onwards, minor transformation products were detected. The maximum amount of a single peak was 1.3% of AR (day 8). The DT_{50} and DT_{90} values

of BYI 02960 in dark and irradiated samples were calculated using a single first order model (see Table B.1.1.3-04).

Table B.8.1.1.3-04 Degradation of BYI 02960 on surface of loam soil Guadalupe

Test System	Half-life		Experimental DT_{50} [days]	Experimental DT_{90} [days]
	Kinetic Model	Chi^2 Error		
Dark, Label PYM	SFO	0.41	> 1000	> 1000
Irradiated, Label PYM	SFO	0.61	99.6	331.0
Dark, Label FUR	SFO	0.29	419.2	> 1000
Irradiated, Label FUR	SFO	0.32	109.3	363.2

SFO = single first order

Conclusions

Major Outcomes of Study

Overall the soil photolytical degradation of BYI 02960 was very slow. The degradation in irradiated test systems was slightly less slow compared to the degradation observed in dark test systems. Based on the experimental DT_{50} values of 99.6 and 109.3 days for [pyridinymethyl-^{14}C] BYI 02960 and [furanone-4-^{14}C] BYI 02960, respectively, the DT_{50} values of BYI 02960 under environmental conditions were calculated to be 358 and 405 solar summer days at Los Angeles, California, USA, 466 and 527 days at Athens, Greece and 638 and 722 solar summer days at Tokyo, Japan.

Significance of Results to Environmental Behavior of BYI 02960

Direct phototransformation of BYI 02960 on soil surfaces is not regarded as a relevant degradation process in the environment. Based on the experimental DT_{50} values of 99.6 and 109.3 days for [PYM-^{14}C] BYI 02960 and [FUR-^{14}C] BYI 02960, respectively, the DT_{50} values of BYI 02960 under environmental conditions were calculated to be 358 and 405 solar summer days at Los Angeles, California, USA, 466 and 527 days at Athens, Greece and 638 and 722 solar summer days at Tokyo, Japan. The soil photolytic DT_{50} for North Europe (London) is 582 days for the [PYM-^{14}C] BYI 02960 and 659 days for the [FUR-^{14}C] BYI 02960.

Remarks

The soil photolysis study is acceptable and the results are reliable.

B.8.1.2 Rate of degradation in soil (Annex IIA 7.2; Annex IIIA 9.1)

The laboratory studies presented in paragraph B.8.1.1 (route of degradation in soil) were also designed to derive information on the rate of degradation of flupyradifurone (BYI 02960) and its significant metabolites under standardized laboratory conditions in soil. In this chapter the methods and results of the respective kinetics calculations were described in more detail. In addition, a separate experimental degradation study was performed with 6-CNA, a major aerobic soil metabolite.

B.8.1.2.1 Laboratory studies (Annex IIA 7.2; Annex IIIA 9.1)

Rate of degradation; parent substance

The degradation rate for the studies performed for flupyradifurone is briefly discussed under chapter B.8.1.1 and these studies IIA 7.1.1/01-7.1.1/06 are on the route of degradation and are also used for rate IIA 7.2.1/01-7.2.1/10. Evaluation of the degradation kinetics of the aerobic soil degradation studies described under paragraph B.8.1.2.1 has been performed to derive EU trigger endpoints and model input parameters. The endpoints are derived accoriding to the FOCUS kinetics (2006) KINGUI was used to fit the measured parameters and obtain the endpoints.

Summary

The route of degradation and experimental design for study 7.1.1/01 has been described under paragraph B.8.1.1. The best fit kinetic for “trigger evaluation” was obtained of 68.8 days was calculated for BYI 02960 in the tested soils under aerobic conditions.

Table B.8.1.2.1-01 Synopsis of ”trigger” best-fit degradation kinetics calculated for BYI 02960

		Parent BYI 02960

Materials and methods

Materials

Materials used in this study are comprehensively described in paragraph B.8.1.1.

Method

Determination of Degradation Kinetics

The parameters of all three kinetic models were estimated by non-linear optimization to the measured data with the software KinGUI v.1.1. The best fit model was chosen on the basis of the goodness of fit as judged by visual assessment and on the chi^2 scaled-error criterion.

Results

The input parameters used for the model of the four soils are given in Table B.8.1.2.1-02. The graphical results of the parameter estimation are given in Figure B.8.1.2.1-01 to Figure B.8.1.2.1-04.

Table B.8.1.2.1-02 Percentage of BYI 02960 used as input parameters for modelling

	DFOP *	**56.4**	**265.1**	**1.6945**
Geometric mean	**DFOP ***	**68.8**	**331.3**	

*: best fit (values bold typed)
SFO: Single first-order

FOMC: First-order multi compartment
DFOP: Double first-order in parallel

The fit of the single first-order (SFO) model was less good than the fits of the biphasic models first-order multi compartment (FOMC) and double first-order in parallel (DFOP). The latter two models however were equivalent, concerning the visual assessment as well as the marginal difference in chi^2 error (< 3 %).

Where there is significant extrapolation the FOMC model is not suitable for prediction of DT_{90} values, since unrealistic DT_{90} values are estimated that are far outside the study duration. Therefore as the FOMC and DFOP models gave equivalent fits the DFOP model was selected for evaluation of the trigger end-points for all soils.

Overall, the geometric mean of the DT_{50} and the DT_{90} values for degradation of BYI 02960 in the tested soils under aerobic conditions at 20 °C were 68.8 and 331.3 days, respectively.

Conclusions

The current laboratory study demonstrated that [pyridinylmethyl-^{14}C] BYI 02960 is degraded in soil under aerobic conditions with geometric mean DT_{50} and the DT_{90} values in the tested soils under aerobic conditions at 20°C of 68.8. An overall summary of the “best-fit” trigger values for all soils is given Table B.8.1.2.1-21.

Remarks

The RMS does not agree with the argument of the authors that DFOP is preferred because it gave lower values of the $DegT_{90}$ than FOMC. FOCUS (2006) developed procedures for selecting the most suitable kinetic model depending on the intended use of the endpoint (trigger value or modelling input).

1. The measurements show a small bi-phasic pattern, so the RMS agrees with the authors that the SFO fits are poor because the residuals show systematic deviations. Although, the authors did not perform the advised modified fitting procedure for the SFO fits (relevant for this case: constrain the initial concentration), the RMS thinks that constraining the initial concentration would improve the fit.
2. Considering deriving endpoints to be used as triggers (Figure 7-1, page 110 FOCUS, 2006), the next step in the flow chart is to determine which of the models (FOMC or DFOP) is best. For all four soils it is not possible to decide from the visual assessment of the fits which model (FOMC, DFOP) gives a better fit; fits are equally good. Comparing the statistical output showed that for soil AX and DD FOMC gives a better fit and for soils HF and HN DFOP gives a better fit based on chi^2 error.
3. Considering deriving degradation parameters for modelling (Figure 7-2, page 114 FOCUS, 2006), DFOP is preferred because 10% of the initially measured concentration was not

reached within the experimental period. Based on this the endpoints depending on its intended use and in line with FOCUS (2006) are shown below.

All endpoints for 'model input' were based on DFOP. The endpoints for 'trigger value' were based on DFOP for HF and HN and on FOMC for AX and DD.

Table B.8.1.2.1-03a Summary of the kinetic evaluation for and trigger and modelling values according to FOCUS

Soil	Kinetic model	Parent BYI 02960 Trigger		Parent BYI 02960 Modelling	
		DT_{50} (d)	DT_{90} (d)	DT_{50} (d)	DT_{90} (d)
AXXa	SFO	70.3	233.6	70.3	233.6
	FOMC	**62.9**	**>1000**	62.9	>1000
	DFOP	63.4	443.3	**63.4**	**443.3**
HF	SFO	54.4	180.6	54.4	180.6
	FOMC	50.8	270.2	50.8	270.2
	DFOP	**52.4**	**209.3**	**52.4**	**209.3**
HN	SFO	112.6	373.9	112.6	373.9
	FOMC	**134.8**	**>1000**	134.8	>1000
	DFOP	120.0	489.7	**120.0**	**489.7**
DD	SFO	60.1	199.8	60.1	199.8
	FOMC	**55.2**	**398.9**	55.2	398.9
	DFOP	56.4	265.1	**56.4**	**265.1**

SFO: Single first-order
FOMC: First-order multi compartment
DFOP: Double first-order in parallel

The extraction methods used are appropriate and the total recovery of the radioactivity was satisfactory (96-102%).

The RMS concludes that the study has been well conducted and that its results (i.e. decline curves of BYI 02960) are in line with the draft guidance on time dependent sorption and are suitable to be used in a kinetic analysis to calculate timedependent sorption parameters.

According to the autors of the study best fit rate of degradation values were all obtained with the DFOP model. As pointed out in the evaluation above RMS does not agree. However, the new geometric mean trigger endpoint is almost similar and therefor the RMS suggests to use the value obtained by the applicant. The geometric mean for persistence is 68.8 days (based on the DFOP values). The RMS agrees to use this value as endpoint for [PYR-^{14}C] BYI 02960.

Summary

The route of degradation and experimental design has been described under in paragraph B.8.1.1.

The best fit kinetic for "trigger evaluation" was obtained by double first-order kinetics. A geometric mean a half-life of 56.2 days was calculated for BYI 02960 in the tested soils.

Table B.81.2.1-04 Synopsis of "trigger" half-lives calculated for BYI 02960

Soil (soil type)	Kinetic model	Parent BYI 02960 DT_{50} [d]	DT_{90} [d]	Chi^2 error [%]
AX (Sandy loam)	DFOP	62.2	390.6	1.55

Materials and methods

Materials

Materials used in this study are comprehensively described in paragraph B.8.1.1.

Method

Determination of Degradation Kinetics

In order to determine the best-fit kinetic model for the degradation of BYI 02960 in soil over time SFO, DFOP and FOMC models were considered. The best fit model was chosen on the basis of the goodness of fit as judged by visual assessment and on the chi^2 scaled-error criterion.

Results

The input parameters used for the model of the four soils are given in Table B.8.1.2.1-05. The graphical results of the parameter estimation are given in Figure B.8.1.2.1-05 to Figure B.8.1.2.1-08.

Kinetics of test Item Degradation

The degradation of the parent compound during the study was evaluated by first-order non-linear regression analysis, a summary of the kinetic analyses for all models is shown in Table B.8.1.2.1-06. Where there is significant extrapolation the FOMC model is not suitable for prediction of DT_{90} values, since unrealistic DT_{90} values are estimated that are far outside the study duration. Therefore as the FOMC and DFOP models gave equivalent fits the DFOP model was selected for evaluation of the trigger end-points for all soils.

Table B.8.1.2.1-06 Summary of the Kinetic Evaluation (for Trigger Values According to FOCUS) of the Degradation of [FUR-^{14}C] BYI 02960 in Aerobic Soils at 20 °C and 55 % of WHCmax)

Soil	Kinetic model	Parent BYI 02960		
		DT50 (d)	DT90 (d)	Chi^2 value

*Bold : best fit (values bold typed)
SFO: Single first-order
FOMC: First-order multi compartment
DFOP: Double first-order in parallel

Conclusions

The current laboratory study demonstrated that [FUR-^{14}C] BYI 02960 is degradable in soils under aerobic conditions with a geomean DT_{50} (trigger endpoint) of 56.2 days for the current study. An overall summary of the "best-fit" trigger values for all soils is given Table B.8.1.2.1-21.

Remarks

The best fit rate of degdration obtained were all with the DFOP model. The geometric mean DT_{50} for persistence is 56.2 days. The RMS agrees to use this value as endpoint for [FUR-^{14}C] BYI 02960.

Kinetics of test Item Degradation

The degradation of the parent compound during the study was evaluated by first-order non-linear regression analysis, a summary of the kinetic analyses for all models is shown in Table B.8.1.2.1-09. In the Springfield soil all models resulted in equivalent fits, the DFOP and FOMC were regarded as less reliable due to the extrapolation required, therefore the SFO was selected. In the Sanger soil the DFOP and FOMC models resulted in better fits, therefore the DFOP was selected as FOMC is less reliable where extrapolation beyond the experimental period is required.

Conclusions

The current laboratory study demonstrated that [FUR-^{14}C] BYI 02960 is degradable in soils under aerobic conditions with DT_{50} values of 58.3 and 228 days. An overall summary of the "best-fit" trigger values for all soils is given in Table B.8.1.2.1-21.

Remarks

The RMS agrees with the applicant to use the SFO fit as best fit for Springfield and DFOP fit for Sanger soil as best fit. The DT_{50} used for persistence is 228 and 58.3 days.

Figure B.8.1.2.1-13 Results of the KinGUI parameter estimation for SFO (left), FOMC (right) and DFOP (under) for HF soil

Kinetics of test Item Degradation

A summary of the DT_{50} and DT_{90} calculations for the test item is given in Table B.8.1.2.1-12. In all cases the fit of the single first-order (SFO) model was less good than the fits obtained with the two biphasic models first order multi compartment (FOMC) and double first order in parallel (DFOP). Although the difference between the latter two models was quite low concerning the chi^2 errors, the visual assessments indicated a better fit of the last sampling points using the DFOP model. Therefore, the DFOP kinetic model was chosen as best fit for all soils.

Table B.8.1.2.1-12 Summary of the kinetic evaluation (for trigger values according to FOCUS)

Soil	Kinetic model	Parent BYI 02960		
		DT50 (d)	DT90 (d)	Chi^2 value
DD	SFO	38.6	128.1	4.1
	FOMC	33.8	178.4	2.0
	DFOP*	**33.9**	**649.6**	1.9

	FOMC	34.1	287.5	2.2
	DFOP*	**34.1**	**329.8**	2.3
Geometric mean	**Best fit**	**41.6**	**486.7**	

* Bold: best fit according to chi2 error or visual assessment
SFO: Single first-order
FOMC:First-order multi compartment
DFOP: Double first-order in parallel

Conclusion

The current laboratory study demonstrated that BYI 02960 is degradable in soils under aerobic conditions The geometric mean of the DT_{50} and the DT_{90} values for degradation of BYI 02960 was 41.6 and 486.7 days, respectively. An overall summary of the “best-fit” trigger values for all soils is given in Table B.8.1.2.1-21.

Remarks

The best fit rate of degdration obtained were all with the DFOP model. The geometric mean for persistence is 41.6 days. The RMS agrees to use this value as endpoint for Ethyl-1-^{14}C BYI 02960.

Kinetics of test Item Degradation

A summary of the DT_{50} and DT_{90} calculation for the test item is given in Table B.8.1.2.1-17. The fit of the single first-order (SFO) model was less good than the fits of the biphasic models first-order multi compartment (FOMC) and double first-order in parallel (DFOP). The latter two models however were equivalent, concerning the visual assessment as well as the marginal difference in chi^2 error. In all cases the chi^2 values of the fits of both, FOMC and DFOP model, were very low (< 3 %).

Where there is significant extrapolation the FOMC model is not suitable for prediction of DT_{90} values, since unrealistic DT_{90} values are estimated that are far outside the study duration. Therefore as the FOMC and DFOP models gave equivalent fits the DFOP model was selected for evaluation of the trigger end-point.

Table B.8.1.2.1-17 Summary of the kinetic evaluation (for trigger values according to FOCUS) of the degradation of [PYR-^{14}C] BYI 02960 in aerobic soil

Soil	Kinetic model	Parent BYI 02960		
		DT_{50} (d)	DT_{90} (d)	Chi^2 value
HF	SFO	43.4	144.2	6.2
	FOMC	33.1	327.0	1.7
	DFOP*	**33.0**	**221.3**	**2.0**

*: best fit (values bold typed)
SFO: Single first-order; FOMC: First-order multi compartment; DFOP: Double first-order in parallel

Conclusions

The current laboratory study demonstrated that [PYR-^{14}C] BYI 02960 is degradable in soils under aerobic conditions with a DT_{50} of 33 days. An overall summary of the "best-fit" trigger values for all soils is given in Table B.8.1.2.1-21.

Remarks

The RMS agrees with the notifier to use DFOP DT_{50} as persistence trigger.

soils	:	two soils; silt loam, sandy laom	acceptability	:	**acceptable**

Summary

The route of degradation and experimental design has been described in paragraph B.8.1.1. The best fit kinetic for "trigger evaluation" was obtained by DFOP or FOMC.

Table B.8.1.2.1-18 Summary of the kinetic evaluation (for trigger values according to FOCUS)

Soil	Kinetic model	Parent BYI 02960		
		DT50 (d)	DT90 (d)	Chi2 value
Springfield	DFOP	242	898	0.7
Sanger	FOMC	56.3	324	1.8

FOMC: First-order multi compartment
DFOP: Double first-order in parallel

Materials and methods

Materials

Materials used in this study are comprehensively described within paragraph B.8.1.1.

Methods Determination of Degradation Kinetics

In order to determine the best-fit kinetic model for the degradation of BYI 02960 in soil over time SFO, FOMC and DFOP models were considered. The goodness of fit was assessed by visual inspection and an error criterion based on a chi-square (χ^2) significance test. In addition to these, the coefficient of determination (r^2) was calculated and reported by the kinetics modelling tool.

Results

The input parameters used for the model of the two soils are given in Table B.8.1.2.1-19. The graphical results of the parameter estimation are given in Figure B.8.1.2.1-15 to Figure B.8.1.2.1-16.

Table B.8.1.2.1-19 Percentage of BYI 02960 used as input parameters for modelling

Soil (Soil type)	Springfield (Silt loam)	Sanger (Sandy loam)
Days after treatment		
0 *	100.8	99.4
0 *	99.2	100.6
3	93.2	96.2
3	95.0	94.3
7	93.2	87.4
7	93.8	87.4
14	90.4	84.6
14	88.1	83.1
28	83.4	67.4
28	83.0	67.2
60	77.3	47.6
60	76.2	46.0
90	70.4	34.8
90	69.8	34.8
120	66.1	29.5
120	65.0	30.5

* Total recovery of radioactivity used as input parameter for DAT 0 sample

Kinetics of test Item Degradation

A summary of the DT_{50} and DT_{90} calculation for the test item is given in Table B.8.1.2.1-20. The fit of the single first-order (SFO) model was less good than the fits of the biphasic models first-order multi compartment (FOMC) and double first-order in parallel (DFOP). The letter two models however were equivalent, concerning the visual assessment as well as the marginal difference in chi^2 error. In all cases the chi^2 values of the fits of SFO, FOMC and DFOP model, were very low (< 3 %). Due to the extent of extrapolation required and the lower reliability of the derived parameters the SFO fit was regarded as more robust.

Figure B.8.1.2.1-15 Results of the KinGUI parameter estimation for SFO (left), FOMC (right) and DFOP (under) for Springfield soil

Figure B.8.1.2.1-16 Results of the KinGUI parameter estimation for SFO (left), FOMC (right) and DFOP (under) for Sanger soil

Table B.8.1.2.1-20 Summary of the kinetic evaluation (for trigger values according to FOCUS)

Soil	Kinetic model	Parent BYI 02960		
		DT50 (d)	DT90 (d)	Chi^2 value
Springfield	SFO	211	400	1.6
	FOMC	429	>1000	0.6
	DFOP*	**242**	**898**	**0.7**
Sanger	SFO	62.2	207	3.0
	FOMC*	**56.3**	**> 1000**	**1.7**
	DFOP	56.3	324	1.8

* Bold: best fit according to chi2 error or visual assessment
SFO: Single first-order
FOMC: First-order multi compartment
DFOP: Double first-order in parallel

Conclusions

The current laboratory study demonstrated that BYI 02960 is degradable in soils under aerobic conditions with "best fit" DT_{50} values of 242 and 56.3. An overall summary of the "best-fit" trigger values for all soils is given in Table B.8.1.2.1-21.

Remarks

The RMS agrees with the notifier to use DFOP for Springfield soil and FOMC for Sanger soils as the best fit DT_{50} of as persistence trigger.

Degradation rates

Summary of the persistence trigger DT_{50} and DT_{90} values in aerobic soil studies

A summary of the DT_{50} and DT_{90} "best-fit" trigger values calculated as described above is given in Table B.8.1.2.1-21.

Table B.8.1.2.1-21 Overall summary of derived DT_{50} and DT_{90} values for degradation of BYI 02960 in aerobic soil (trigger evaluation according to FOCUS kinetics)

Kinetic Evaluation of Laboratory Studies – Modelling endpoints

In addition to the evaluation of trigger values by considering "best-fit" as described above parameters suitable for use in environmental modelling have been separately evaluated in accordance with the procedures of FOCUS kinetics (2006).

STUDY IIA, 7.2.1/07

Characteristics

reference	:	Sur, R., Dorn, S. (2012)	study type	:	kinetic evaluation
year of execution	:	2012	incubation time	:	n.a
GLP statement	:	no	nominal concentration	:	n.a
guideline	:	FOCUS Kinectics (2006) US EPA, OPPTS 835	temperature	:	n.a.
test substance	:	n.a	DT_{50}	:	see results
purity	:	n.a	metabolites	:	see results
soils	:	n.a.	acceptability	:	**acceptable**

Summary

The present report is a supplement to Menke 2011 (study IIA, 7.1.1/01), summarized in paragraph B.8.1.1. It compiles additional raw data of the kinetic evaluation of the degradation of BYI 02960 in soil to determine modelling endpoints. The evaluation followed the recommendations of the FOCUS working group on degradation kinetics. The trigger endpoints of BYI 02960 were derived in the study IIA, 7.2.1/01 and are summarized in Table B.8.1.2.1-21.

Methods

The measured data were taken into account as reported (individual replicates). All experimental data sets and all data points were weighted equally (weighting factor 1), which corresponds to an absolute error model. The initial concentration was fitted.

The goodness of the fits was assessed visually and by the Chi^2 error as described in FOCUS (2006). A single-sided t-test was used to identify the probability that the degradation rate is not significant, that is equal or smaller than zero. A probability t-prob of 0.05 is considered as sufficiently small to obtain significant degradation parameters, which are suitable for modelling purposes (FOCUS 2006).

As outlined in the underlying main report, parameter optimization was carried out with the MATLAB evaluation tool 'KinGUI' (MATLAB 2005 and Bramley 2007) considering alternative kinetic models. The graphs of the model fits are shown in Figure B.8.1.2.1-01 to Figure B.8.1.2.1-04.

Conclusion

The degradation parameters for modelling input are summarized in Table B.8.1.2.1-22. For modelling endpoints the SFO model was considered acceptable for Dollendorf II (DD) and Hoefchen am Hohenseh 4a (HF) and the DFOP model was chosen for Laacher Hof AXXa (Ax) and Hanscheiderhof (HN).

Table B.8.1.2.1-22 Modelling endpoints of BYI 02960

Soil	Kinetic Model	BYI 02960			
		DT_{50} (d)	χ^2 err (%)	Visual Acceptability	t-prob
Ax	DFOP	169.1*	1.1702	Yes	k_1: <0.001 k_2: <0.001
HF	SFO	54.4	2.3139	Yes	<0.001
HN	DFOP	157.5*	1.2373	Yes	k_1: <0.001 k_2: <0.001
DD	SFO	60.1	3.3408	Yes	<0.001

* slow compartment of DFOP model

Remarks

The RMS agrees with the applicant to use the slow phase DT_{50} of the DFOP fits of Ax and HN soils and SFO DT_{50} of HF and DD soils as input parameters for environmental modelling.

STUDY IIA, 7.2.1/08

Characteristics

reference	:	Sur, R., Dorn, S. (2012)	study type	:	kinetic evaluation
year of execution	:	2012	incubation time	:	n.a

soils	:	n.a.	acceptability	:	**acceptable**

Summary

The present report is a supplement to Menke and Unold 2011 (study IIA, 7.1.1/02), summarized in paragraph B.8.1.1. It compiles additional raw data of the kinetic evaluation of the degradation of BYI 02960 in soil to determine modelling endpoints. The evaluation followed the recommendations of the FOCUS working group on degradation kinetics (FOCUS, 2006). The trigger endpoints of BYI 02960 were derived in study IIA, 7.2.1/02 and have been summarized in Table B.8.1.2.1-21.

Method

The measured data were taken into account as reported (individual replicates). All experimental data sets and all data points were weighted equally (weighting factor 1), which corresponds to an absolute error model. The initial amount of the parent was fitted.

The goodness of the fits was assessed visually and by the Chi^2 error as described in FOCUS (2006). A single-sided t-test was used to identify the probability that the degradation rate is not significant, that is equal or smaller than zero. A probability t-prob of 0.05 is considered as sufficiently small to obtain significant degradation parameters, which are suitable for modelling purposes (FOCUS 2006).

As outlined in the underlying main report, parameter optimization was carried out with the MATLAB evaluation tool 'KinGUI' (MATLAB 2005 and Bramley 2007) considering alternative kinetic models. The graphs of the model fits are shown in Figure B.8.1.2.1-05 to Figure B.8.1.2.1-08.

Conclusion

The degradation parameters for modelling input are summarized in Table B.8.1.2.1-23. For modelling endpoints the SFO model was considered acceptable for Dollendorf II (DD) and Hoefchen am Hohenseh 4a (HF) and the DFOP model was chosen for Laacher Hof AXXa (Ax) and Hanscheiderhof (HN).

Table B.8.1.2.1-23 Modelling endpoints of BYI 02960

Soil	Kinetic Model	BYI 02960			
		DT_{50} (d)	χ^2 err (%)	Visual Acceptability	t-prob
Ax	DFOP	141.5*	1.5528	Yes	k_1: <0.001 k_2: <0.001
HF	SFO	40.5	5.2961	Yes	<0.001

DD	SFO	55.1	3.8698	Yes	<0.001

*slow compartment of DFOP model

Remarks

The RMS agrees with the applicant to use the slow phase DT_{50} of the DFOP fits of Ax and HN soils and SFO DT_{50} of HF and DD soils as input parameters for environmental modelling.

STUDY IIA, 7.2.1/09

Characteristics

reference	:	Sur, R., Dorn, S. (2012)	study type	:	kinetic evaluation
year of execution	:	2012	incubation time	:	n.a
GLP statement	:	no	nominal concentration	:	n.a
guideline	:	FOCUS Kinectics (2006) US EPA, OPPTS 835	temperature	:	n.a.
test substance	:	n.a	DT_{50}	:	see results
purity	:	n.a	metabolites	:	see results
soils	:	n.a.	acceptability	:	**acceptable**

Summary

The present report is a supplement to Menke and Unold 2011 (study IIA, 7.1.1/04). It compiles additional raw data of the kinetic evaluation of the degradation of BYI 02960 and the major metabolite DFA in soil to determine modelling endpoints. The evaluation followed the recommendations of the FOCUS working group on degradation kinetics (FOCUS, 2006). The trigger endpoints of BYI 02960 were derived in the study IIA, 7.2.1/04 have been summarized Table B.8.1.2.1-21, the degradation kinetic for the metabolite is summarized in study IIA, 7.2.3/05.

The present kinetics evaluation followed the recommendations of the FOCUS working group on degradation kinetics for modelling endpoints.

Methods

The measured data were taken into account as reported (individual replicates). All experimental data sets and all data points were weighted equally (weighting factor 1).

For all residues used in the kinetic evaluation, the following procedure was applied. Any value below LOD directly before or after a value ≥ LOD was set to 0.5 LOD. The LOD was chosen as 0.5% of applied radioactivity (AR). The remaining values below LOD were excluded from the analysis. The values of the parent compound BYI 02960 at zero days after application (DAT 0) were set to the recovery rate. The reason for this modification is that exactly at the time of application only the parent compound can occur. If metabolites occur at DAT 0, those values are set to zero for the same reason. If recovery rates are >110% or <90%, the values from those sampling points are excluded from the analysis as well.

The kinetic evaluation was performed following the recommendations of FOCUS 2006 to derive environmental fate modelling. All data were equally weighted which corresponds to an absolute error model. Four kinetic models are considered in the testing procedure as recommended by FOCUS 2006: the single first-order (SFO), first-order multiple-compartment (FOMC, Gustafson-Holden), the double-first-order in parallel (DFOP) and the hockey-stick model (HS). The graphs of the model fits are shown in Figure B.8.1.2.1-11 to Figure B.8.1.2.1-13.

Conclusion

For modelling endpoints the SFO model was considered acceptable for Dollendorf II and Hoefchen am Hohenseh 4a and the DFOP model was chosen for Laacher Hof AXXa.

Table B.8.1.2.1-24 DT_{50} of BYI 02960 for modelling

Soil	Kinetic model	DT_{50} [d]	χ^2 err (%)	Visual acceptablity	t-prob
Dollendorf II (DD)	SFO	38.6	4.209	yes	<0.001
Laacher Hof AXXa (Ax)	DFOP	210.2*	1.556	yes	k_1 <0.001 k_2 <0.05
Hoefchen am Hohenseh 4a (HF)	SFO	43.0	6.166	yes	<0.001

*slow compartment of DFOP model

Remarks

The RMS agrees with the applicant to use the slow phase DT_{50} of the DFOP fit of Ax soil and the SFO DT_{50} for HF and DD soils as input parameters for environmental modelling.

STUDY IIA, 7.2.1/10

Characteristics

reference	:	Sur, R., Dorn, S. (2012)	study type	:	kinetic evaluation
year of execution	:	2012	incubation time	:	n.a
GLP statement	:	no	nominal concentration	:	n.a
guideline	:	FOCUS Kinectics (2006) US EPA, OPPTS 835	temperature	:	n.a.
test substance	:	n.a	DT_{50}	:	see results
purity	:	n.a	metabolites	:	see results
soils	:	n.a.	acceptability	:	**acceptable**

Summary

The present report is a supplement to Menke and Unold 2011 (IIA 7.1.1/05). It compiles additional raw data of the kinetic evaluation of the degradation of BYI 02960 and 6-CNA in soil to determine modelling endpoints. The evaluation followed the recommendations of the FOCUS working group on degradation kinetics (FOCUS, 2006). The trigger endpoints of BYI 02960 were derived in the study IIA, 7.2.1/05 have been summarized in Table B.8.1.2.1-21, the degradation kinetics for the metabolite is summarized in study IIA, 7.2.3/03.

Methods

For all residues used in the kinetic evaluation, any value below LOD directly before or after a value ≥ LOD was set to 0.5 LOD. The LOD was chosen as 0.5% of applied radioactivity (AR) which corresponds to 0.005 mg/kg. The values of the parent compound BYI 02960 at zero days after application (DAT = 0) were set to the recovery rate. The reason for this modification is that exactly at the time of application only the parent compound can occur. If metabolites occur at DAT 0, those values are set to zero for the same reason. If recovery rates are >110% or <90%, the values from those sampling points are excluded from the analysis.

For the kinetic modelling analysis the mathematical software tool MatLab with a user shell “KinGUI” were employed (MatLab 2005, Bramley, 2007). The kinetic evaluation was performed following the recommendations of FOCUS 2006 to derive degradation parameters for environmental fate modelling. Four kinetic models are considered in the testing procedure as recommended by FOCUS 2006: the single first-order (SFO), first-order multiple-compartment (FOMC, Gustafson-Holden), the double-first-order in parallel (DFOP) and the hockey-stick model (HS). The graphs of the model fits are shown in Figure B.8.1.2.1-14.

Conclusion

The degradation of BYI 02960 was best described with bi-phasic kinetics for modeling endpoints. The DFOP model was used to describe the kinetics for Hoefchen am Hohenseh 4a.

Table B.8.1.2.1-25 DT_{50} of BYI 02960 for modelling

Soil	Kinetic model	DT_{50} [d]	χ^2 err (%)	Visual acceptablity	t-prob
Hoefchen am Hohenseh 4a (HF)	DFOP	90.0*	1.7060	yes	$k_1 < 0.001$ $k_2 < 0.001$

*slow compartment of DFOP model

Remarks

The RMS agrees with the applicant to use the slow phase DT_{50} of the DFOP fit of HF soil as input parameters for environmental modelling.

STUDY IIA, 7.2.1/03

Characteristics

Remarks

The RMS agrees with the applicant to use the SFO DT_{50} of Springfield and Sanger soils as input parameters for environmental modelling.

Summary of Modelling Input DT_{50} values in aerobic soil studies

A summary of the DT_{50} values calculated for modelling input is given in Table B.8.1.2.1-28. Considering the moisture content of the soils during incubation the DT_{50} was corrected to pF2, for the studies performed on European soils no correction for soil moisture content was required, for the studies on US soils the correction factor as outlined below was employed.

Details of the soil moisture correction are given in the PEC reports included in the Annex III (Sur and Ellerich, 2012, M-427646-01-1, study IIA1, 9.7/01).

Table B.8.1.2.1-28 Overall summary of derived DT_{50} values for degradation of BYI 02960 in aerobic soil - modelling input parameters

Studies performed with and for the aerobic degradation rate of metabolites are described here.

Rate of degradation; metabolite added as parent

Metabolite 6-CNA

The rate of degradation of the major metabolite 6-CNA has been investigated in 3 soils. The metabolite is also a common metabolite to the insecticide acetamiprid, this study has been evaluated in the context of the review report for the active substance acetamiprid, SANCO/1392/2001 – Final, 16 June 2004. Access to the study has been granted by the owners Nippon Soda (Nisso). Only a brief summary of the study is presented here. Due to changes in the requirements for kinetic evaluation a new kinetic evaluation of the study was performed and is described in study IIA, 7.2.3/02

STUDY IIA, 7.2.3/01

Characteristics

reference	:	Lowden, P., Oddy, A.M., Jones, M.K. (1997)	study type	:	aerobic degradation
year of execution	:	1997	incubation time	:	119 d
GLP statement	:	no	nominal concentration	:	130 g ha^{-1}
guideline	:	not specified	temperature	:	20°C
test substance	:	[14C]-IC-O (equivalent to 6-CNA)	DT50	:	see results
purity	:	radiochemical purity >988% 95.76% (batch no. CFQ 9603)	metabolites	:	not applicable
soils	:	three soils; sandy loam, clay, loam	acceptability	:	**acceptable**

Summary

The study was performed to examine the rate of degradation of [^{14}C]-IC-O (equivalent to 6-CNA) at 20± 2°C. Three soils were selected, which were a sandy loam (RPAL reference 97/03), a silty clay loam (RPAL reference 97/04) and a clay loam (RPAL reference 97/05). Portions of soil (approximately 100 or 500 g oven dried equivalent) were placed in uniquely labelled soil flasks and treated with [14C]-IC-O solution at a rate equivalent to 130 g ha^{-1}). The moisture content was adjusted to 45% of the maximum water holding capacity and maintained at that level throughout the study. The flasks were placed in a closed system maintained in the dark in which moist, carbon-dioxide-free air was continuously blown over the soils, then through ethylene glycol followed by potassium hydroxide. At intervals up to and including 119 days after treatment soil samples were extracted with solvent (methanol/ammonium acetate 2M (80:20 v/v)) or acetonitrile water (80:20 v/v) and the extracts containing sufficient radioactivity were examined by high performance liquid chromatography (HPLC).

The unextracted radioactivity was assayed using a combustion technique. Selected extracts were further examined by liquid chromatography followed by mass spectrometry (LC-MS). Parts for the original DAR from acetamiprid on metabolite [^{14}C]-IC-O are included.

Materials and Methods :

The rate of degradation of ^{14}C-IC-0 was studied in three soils (sandy loam, silty clay loam and clay loam, Table B.8.1.2.1-1) at 20 °C for a period of 119 days. Portions of soil were placed in labelled soil flasks and treated with ^{14}C-IC-0 solution at a rate equivalent to 130 g/ha. The soils were brought to 45% of their maximum moisture holding capacity by the addition of deionised water. Two flasks from each soil type were taken and extracted. At each sampling point two further flasks from each soil were taken along with their associated ethylene glycol and potassium hydroxide traps. The sampling points were 1, 3, 5, 7, 10, 14, 32, 60, and 119 days after treatment.

Table B.8.1.2.1-1 : Physico-Chemical Properties of Soils :

Soil Type	Sand (%)	Silt (%)	Clay (%)	Org. C (%)	pH	CEC [1)]	MWC (%)	Bio-mass [2)] (initial)	Bio-mass [2)] (final)
CL	25.2	50.7	24.2	1.7	7.2	23.2	63.1	230	338
SL	55.7	36.2	8.2	3.1	6.7	8.7	86.0	804	428
SiCL	19.9	49.5	30.6	3.8	7.8	78.9	106.7	1047	978

1) meq/100g

2) µg C per g of soil

The soil samples were extracted with solvent (methanol/ammonium acetate 2M, 80:20 v/v) or acetonitrilewater (80:20 v/v) and the extracts containing sufficient radioactivity were analysed by HPLC. The unextracted radioactivity was assayed using a combustion technique. Selected extracts were further examined by LC-MS.

Recoveries of applied radioactivity were generally good throughout the study with all but three of the individual flasks at each time point falling within the range 90 -110%. The major metabolite detected was carbon dioxide which was trapped in the potassium hydroxide traps and accounted for approximately 84% of the applied dose in the sandy loam, about 92% in the UK silty clay loam and 84% in the clay loam at the end of the study.

The percentage of material in the solvent extract declined with time from over 90% at day 0 to less than 2% at day 119. This fall was initially concomitant with an increase in unextractable residues and with the decrease in radioactivity associated with the soil as the compound was mineralised to carbon dioxide.

Results:

Recoveries of the applied radioactivity were within the range 90-110%. The non-extractable residues reached a maximum level which ranged in the three soils from 9% to 14% of the applied dose, by the end of the study (day 119). Respectively, volatile radioactivity reached maximum levels between 84 and 92%, at day 119, in the three soils used. Analysis showed that the only volatile product was carbon dioxide which was trapped in the potassium hydroxide traps. Chromatographic analysis of soil extracts showed the presence of IC-0 and two very minor metabolites. Spectroscopic examination of the extracts confirmed the presence of parent IC-0 (Table B.8.1.2.1-2). The two very minor compounds were transient metabolites and were both less than 3% maximum in all three soils, of applied dose.

Table B.8.1.2.1-2 : Summary table of IC-0 concentrations (% applied dose) based on HPLC results

	Days						
Soil Type	**0**	**1**	**3**	**5**	**7**	**10**	**14**
Sandy loam	100.06	90.38	60.42	35.6	12.76	8.06	2.5
Silty clay loam	94.58	75.54	47.84	19.11	8.57	1.78	1.47
Clay loam	93.35	89.36	76.68	62.39	44.32	20.21	9.7

The DT_{50} for IC-0 was calculated from the HPLC results, using the KIM computer program, and was found to be 3.5 days in the sandy loam, 2.9 days in the silty clay loam and 6.5 days in the clay loam. The DT_{90} was found to be 8.3 days in the sandy loam, 6.6 days in the silty clay loam and 13.3 days in the clay loam.

Chromatographic analysis of the soil extracts showed the presence of IC-O and two very minor metabolites. Spectroscopic examination of the extracts confirmed the presence of parent IC-O. The two very minor compounds were transient metabolites and were both less than 3% maximum in all three soils.

Remarks

The aerobic soil degradation study for 6-CNA is acceptable.

STUDY IIA, 7.2.3/02

Characteristics

reference	:	Sur, R., Dorn, S. (2012)	study type	:	kinetic evaluation
year of execution	:	2012	incubation time	:	n.a
GLP statement	:	no	nominal concentration	:	n.a
guideline	:	FOCUS Kinectics (2006) US EPA, OPPTS 835	temperature	:	n.a.
test substance	:	n.a	DT_{50}	:	see results
purity	:	n.a	metabolites	:	see results
soils	:	n.a.	acceptability	:	**acceptable**

Summary

The aerobic degradation of 6-chloronicotinic acid (6-CNA) was kinetically evaluated based on a laboratory study with three soils (Lowden et al. 1997, IIA 7.2.3/01). The evaluation followed the recommendations of the FOCUS working group on degradation kinetics and considered trigger and

modelling endpoints (Table B.8.1.2.1-29). Degradation of 6-CNA was best described by single first-order (SFO) kinetics in all cases.

Table B.8.1.2.1-29 Trigger and Modelling DT_{50} and DT_{90} of 6-CNA

Compound	Soil	Kinetic model	DT_{50} [d]	DT_{90} [d]
6-CNA	Aldham's Farm	SFO	2.9	9.7
	Flint Hall Farm	SFO	2.2	7.4
	Boarded Barns Farm	SFO	5.3	17.5

Materials and methods

The biotransformation of [^{14}C]-6-CNA, labelled in the 2,6 positions of the pyridine ring was studied in three soils from the UK.

Measured data of individual replicates were taken into account and all experimental data sets and all data points were weighted equally (weighting factor 1). For all residues used in the kinetic evaluation, any value below LOD directly before or after a value ≥ LOD was set to 0.5 LOD. The LOD was chosen as 3.88% of applied radioactivity (AR) which corresponds to 0.005 mg/kg. The remaining values below LOD were excluded from the analysis. The values of 6-CNA at zero days after application (DAT = 0) were set to the recovery rate because exactly at the time of application only the parent compound can occur. Values from sampling points with recovery rates >110% or <90% were excluded from the analysis.

Method

For the kinetic modelling analysis the mathematical software tool MatLab with a user shell "KinGUI" were employed (MatLab 2005, Bramley, 2007). The kinetic evaluation was performed following the recommendations of FOCUS 2006 to derive degradation parameters for comparison with triggers and for tier-1 PEC_{soil} calculation as well as for environmental fate modelling. Four kinetic models are considered in the testing procedure as recommended by FOCUS 2006: the single first-order (SFO), first-order multiple-compartment (FOMC, Gustafson-Holden), the double-first-order in parallel (DFOP) and the hockey-stick model (HS). Testing of DFOP and HS models was not required.

Results

The input parameters used for the model of the three soils are given in Table B.8.1.2.1-30. The graphical results of the parameter estimation are given in Figure B.8.1.2.1-17 to Figure B.8.1.2.1-19.

[a] not applicable

Conclusions

The current laboratory study demonstrated that 6-chloronicotinic acid (6-CNA) is well degradable under aerobic conditions in soils with a DT_{50} of 2.2 to 5.3 days. The values derived by SFO kinetics are acceptable for risk assessment of the persistence criteria for metabolite 6-CNA and as input for environmental exposure modelling.

Remarks

The kinetic evaluation of the soil degradation study of 6-CNA is acceptable and the values are used as trigger and model endpoints.

Rate of degradation; modelling of metabolite degradation from parent study

STUDY IIA, 7.2.3/03

Characteristics

reference	:	Sur, R., Dorn, S. (2012)	study type	:	kinetic evaluation

soils	:	n.a.	acceptability	:	**acceptable**

Summary

The aerobic degradation of [pyridine-2,6-^{14}C] BYI 02960 was kinetically evaluated based on a laboratory study with one soil (Menke and Unold, 2011; IIA, 7.1.1/05). During the study the metabolite 6-chloronicotinic acid (6-CNA) reached a maximum percentage of 2.5% of AR at DAT 7. The present kinetics evaluation followed the recommendations of the FOCUS working group on degradation kinetics and considered trigger and modelling endpoints for the metabolite 6-CNA, the end-points for BYI 02960 were described under paragraph B.8.1.2.1 above.

Degradation of metabolite 6-CNA could be described with SFO kinetics. The pathway fit (FOMC parent / SFO metabolite) was considered acceptable for trigger endpoints while the pathway fit DFOP parent / SFO metabolite was used for modelling endpoints.

Table B8.1.2.1-32 Trigger DT_{50} and DT_{90} of 6-CNA

Compound	Soil	Kinetic model	DT_{50} [d]	DT_{90} [d]
6-CNA	Hoefchen am Hohenseh 4a	SFO	3.1	10.4

Table B.8.1.2.1-33 DT_{50} of 6-CNA for modelling

Compound	Soil	Kinetic model	DT_{50} [d]	Formation fraction pa→6-CNA
6-CNA	Hoefchen am Hohenseh 4a	SFO	3.0	0.2660

Materials and Methods

Materials

The biotransformation of [pyridine-2,6-^{14}C] BYI 02960 was studied in a one European soil (silt loam, Hoefchen am Hohenseh 4a) for 118 days under laboratory aerobic conditions at 20±1°C in the dark (Menke & Unold, 2011, IIA 7.1.1/05).

The test item in the extracts declined from 96.3% of AR at DAT 0 to 22.7% at the end of the study. Only minor transformation products (all mean values were ≤ 2.5% of AR) were detected in the extracts, the maximum amount was detected on DAT 7 with 2.5% of AR and was identified as 6-CNA by co-chromatography. Towards the end of the study, the amounts decreased below the detection limit. Measured data of individual replicates were taken into account and all experimental data sets and all data points were weighted equally (weighting factor 1).

For all residues used in the kinetic evaluation, any value below LOD directly before or after a value ≥ LOD was set to 0.5 LOD. The LOD was chosen as 0.5% of applied radioactivity (AR) which corresponds to 0.005 mg/kg. The values of the parent compound BYI 02960 at zero days after application (DAT = 0) were set to the recovery rate. The reason for this modification is that exactly at the time of application only the parent compound can occur. If metabolites occur at DAT 0, those values are set to zero for the same reason. If recovery rates are >110% or <90%, the values from those sampling points are excluded from the analysis.

Methods

Determination of Degradation Kinetics

For the kinetic modelling analysis the mathematical software tool MatLab with a user shell "KinGUI" were employed (MatLab 2005, Bramley, 2007). The kinetic evaluation was performed following the recommendations of FOCUS 2006 to derive degradation parameters for comparison with triggers and for tier-1 PEC_{soil} calculation as well as for environmental fate modelling. Four kinetic models are considered in the testing procedure as recommended by FOCUS 2006: the single first-order (SFO), first-order multiple-compartment (FOMC, Gustafson-Holden), the double-first-order in parallel (DFOP) and the hockey-stick model (HS).

Results

The input parameters used for the model of the three soils are given in Table B.8.1.2.1-33. The graphical results of the parameter estimation are given in Figure B.8.1.2.1-20 to Figure B.8.1.2.1-21.

[c] excluded because below detection limit

Kinetics of TEST Item Degradation

The appropriate models for trigger and modelling endpoints were selected according to visual assessment and χ^2 error and are presented in in Table B.8.1.2.1-35 for the metabolite 6-CNA.

Table B.8.1.2.1-35 χ^2 error, t-probability (significance of deg. rate) and visual acceptability of different kinetic models for 6-CNA in soil Hoefchen am Hohenseh

Compound	Criterion	FOMC parent/ SFO metabolite	DFOP parent/ SFO metabolite
6-CNA	χ^2 err [%]	16.9529	15.3680
	Visual acceptability	Yes	Yes
	t-prob	0.0937	<0.001
	Formation fraction 6-CNA	0.2534	0.2660
	Endpoint	Trigger	Modelling

Conclusions

The current laboratory study demonstrated that 6-chloronicotinic acid is very well degradable (DT_{50}, 3 days) under aerobic conditions in soils.

Remarks

The RMS considers the endpoint obtained acceptable and reliable. Altough, the χ^2 error was slightly above 15% this was still considered acceptable by the RMS in case of a metabolite and, thus, the results may be used for modelling endpoints.

Sanger	Modelling (SFO-SFO)	24.8	82.4	0.6936

Materials and Methods

This study is comprehensively described within report IIA 7.1.1/06.

Determination of Degradation Kinetics

In order to determine the best-fit kinetic model for the degradation of 6-CNA the models SFO parent and SFO for 6-CNA plus DFOP for parent and SFO for 6-CNA were used. The goodness of fit was assessed by visual inspection and an error criterion based on a chi-square (χ^2) significance test. In addition to these, the coefficient of determination (r^2) was calculated and reported by the kinetics modelling tool.

Results

The input parameters used for the model of the soil is given in Table B.8.1.2.1-37. The graphical results of the parameter estimation are given in Figure B.8.1.2.1-22 to Figure B.8.1.2.1-23.

120	29.5	7.2	30.5	9.3

Figure B.8.1.2.1-22 Results of the KinGUI parameter estimation for DFOP for BYI 02960 and SFO for 6-CNA used for trigger values for 6-CNA

Figure B.8.1.2.1-23 Results of the KinGUI parameter estimation SFO for BYI 02960 and SFO for 6-CNA used for modelling values for 6-CNA

Kinetics of test Item Degradation

For the observed degradation of BYI 02960 and the formation and decline of 6-CNA in the Sanger sandy loam soil, SFO-SFO and DFOP-SFO kinetic models were used. Both approaches gave an acceptable fit to the measured data. However, the visual examination of the observed data and models, as well as the χ^2 scaled error statistic and the coefficient of determination (r^2), showed that DFOP-SFO is the best-fit model.

The parameter values from the best-fit DFOP-SFO model should be used with care for extrapolation purposes (e.g. for environmental modelling), since the DFOP parameters are highly inter-correlated (r^2 > 0.97 between k_1, k_2 and g) and the parameter estimates have large standard deviations. The parameter values from the SFO –SFO model are more robust for extrapolation purposes, despite the slightly worse fit of the model to the measured data.

Table B.8.1.2.1-38 Summary of the kinetic evaluation formation and decline of 6-CNA

Soil	Kinetic model		6-CNA					
	Parent	6-CNA	DT50 (d)	DT90 (d)	Chi^2 value	t-prob	Visual assessment	Formation fraction
Sanger	DFOP	SFO	36.6*	121	13.8	<0.001	+	0.5272
	SFO	SFO	24.8#	82.4	15.1	<0.001	+	0.6936

* best fit trigger value
# modelling value

Conclusions

The current laboratory study demonstrated that 6-CNA is degraded in soil with a best fit DT_{50} of 36.6 days and a modelling DT_{50} (non-normalised) of 24.8 days.

Remarks

The RMS considers the endpoints obtained acceptable and reliable. Altough, the χ^2 error was slightly above 15% this was still considered acceptable for metabolites and, thus, the results may be used for modelling endpoints.

Summary

The present report is a supplement to Menke and Unold 2011, summarized in study IIA, 7.1.1/04. It compiles additional raw data of the kinetic evaluation of the degradation of BYI 02960 and the major metabolite DFA in soil to determine modelling endpoints. The evaluation followed the recommendations of the FOCUS working group on degradation kinetics (FOCUS, 2006). The degradation parameters for the metabolite are summarized below.

The present kinetics evaluation followed the recommendations of the FOCUS working group on degradation kinetics for modelling endpoints.

Materials and methods

Materials

This study is comprehensively described within report IIA 7.1.1/04

Measured data of individual replicates were taken into account and all experimental data sets and all data points were weighted equally (weighting factor 1).

For all residues used in the kinetic evaluation, the following procedure was applied. Any value below LOD directly before or after a value ≥ LOD was set to 0.5 LOD. The LOD was chosen as 0.5% of applied radioactivity (AR). The remaining values below LOD were excluded from the analysis. The values of the parent compound BYI 02960 at zero days after application (DAT 0) were set to the recovery rate. The reason for this modification is that exactly at the time of application only the parent compound can occur. If metabolites occur at DAT 0, those values are set to zero for the same reason. If recovery rates are >110% or <90%, the values from those sampling points were excluded from the analysis.

Methods

Determination of Degradation Kinetics

For the kinetic modelling analysis the mathematical software tool MatLab with a user shell “KinGUI” were employed (MatLab 2005, Bramley, 2007). The kinetic evaluation was performed following the recommendations of FOCUS 2006 to derive degradation parameters for comparison with triggers and for tier-1 PEC_{soil} calculation as well as for environmental fate modelling. Four kinetic models are considered in the testing procedure as recommended by FOCUS 2006: the single first-order (SFO), first-order multiple-compartment (FOMC, Gustafson-Holden), the double-first-order in parallel (DFOP) and the hockey-stick model (HS).

Results

The input parameters used for the model of the three soils are given in Table B.8.1.2.1-41 to Table B.8.1.2.1-43. The graphical results of the parameter estimation are given in Figure B.8.1.2.1-24 to Figure B.8.1.2.1-28.

Kinetics of test Item Degradation

The appropriate models for trigger and modelling endpoints were selected according to visual assessment and χ^2 error and are presented in the following table.

Table B.8.1.2.1- 44 χ^2 error, t-probability (significance of degradation rate) and visual acceptability of different kinetic models for DFA in soil

Soil	Criterion	BYI 02960-DFA	
		DFOP or FOMC** parent/ SFO metabolite	SFO parent/ SFO metabolite
Dollendorf II	χ2 err [%]	5.412	5.169
	Visual acceptability	Yes	Yes
	t-prob	<0.001	<0.001
	Formation fraction DFA	0.7477	0.9087
	Endpoint	Trigger	Modelling
Laacher Hof AXXa	χ2 err [%]	8.359	n.r.

Hoefchen am Hohenseh 4a	χ2 err [%]	7.394	4.033
	Visual acceptability	Yes	Yes
	t-prob	<0.001	<0.001
	Formation fraction DFA	0.7359	1.0000
	Endpoint	Trigger	Modelling

n.r. = relevant; ** for parent DFOP kinetic model used for DD and Ax soil and FOMC kinetic model used for HF soil

Conclusions

The current laboratory study demonstrated that difluoroacetic acid is degradable under aerobic conditions in soils. The tigger endpoints obtained for DFA, where parent was dosed, were obtained from DFOP (DD and Ax soil) or FOMC (HF soil) kinetic fit for the parent and SFO kinetic fit for DFA. The modelling endpoints obtained for DFA, where parent was, dosed were obtained from SFO (DD and HF soil) or DFOP (Ax) kinetic fit for the parent and SFO kinetic fit for DFA.

Remarks

The RMS considers the endpoints obtained for trigger and modelling acceptable and reliable.

Summary

Soil dissipation of BYI 02960 under European field conditions was investigated after application of BYI 02960 SL 200 on bare soil plots at sites in Monheim, Burscheid and Hanscheider Hof (all Germany), Great Chishill (United Kingdom), Albaro (Italy), and Vilobi d'Onyar (Spain). An application was also made in Chilly (Northern France), however the trial was aborted due to heavy rain shortly after application. The sites are located in the ecoregions Northern and Southern Europe.

BYI 02960 SL 200 was sprayed once pre-emergence onto the soil at 1.25 L/ha, corresponding to 250 g BYI 02960/ha in 180 to 320 sqm plots. The measured initial zero-time concentrations corresponded from 91% to 107% of the intended dose rate (250 g/ha). The control plots were at least 5 m away from the treated plots.

Soil samples were taken (nominally) at 0 to 540 days post-application to a maximum depth of 100 cm and analyzed for BYI 02960 and its soil metabolite DFA (difluoroacetic acid).

Soil samples of 20 g were extracted in a microwave extractor with 50 mL of acetonitrile/water (4/1, v/v). Possible matrix effects were eliminated by using an internal standard solution of isotopically labeled reference items which was added to the extracts of samples. Then a subsample was filtrated to remove fine particles of the soil. Identification and quantitation of the test items was done by high performance liquid chromatography using MS/MS detection in the Multiple Reaction Monitoring mode. The method was validated using three different soils. The limit of quantitation (LOQ) was 5.0 µg/kg, and the limit of detection (LOD) was 1.5 µg/kg for both analytes.

At Monheim (Germany), the amount of BYI 02960 determined in 0-10 cm at day 0 was 237 g/ha, which is 95% of the nominal application rate. BYI 02960 declined from 237 g BYI 02960/ha in soil at day 0 to 35.6 g/ha at day 545, corresponding to 15% of the applied amount. BYI 02960 had a DT_{50} of 41.0 days, and a DT_{90} of 749 days.

At Great Chishill (United Kingdom), the amount of BYI 02960 determined in 0-10 cm at day 0 was 236 g/ha, which is 94% of the nominal application rate. BYI 02960 declined from 236 g BYI 02960/ha in soil

at day 0 to 70.2 g BYI 02960/ha in soil at day 552, corresponding to 29.8% of the applied amount. BYI 02960 had a DT_{50} of 251 days, and a DT_{90} of >1000 days.

At Burscheid (Germany), the amount of BYI 02960 determined in 0-10 cm at day 0 was 245 g/ha, which is 98% of the nominal application rate. BYI 02960 declined from 245 g BYI 02960/ha in soil at day 0 to 17.9 g/ha at day 540, corresponding to 7.3% of the applied amount. BYI 02960 had a DT_{50} of 42.8 days, and a DT_{90} value of 484 days.

At Albaro (Italy), the amount of BYI 02960 determined in 0-10 cm at day 0 was 268 g/ha, which is 107% of the nominal application rate. BYI 02960 declined from 268 g BYI 02960/ha in soil at day 0 to 7.8 g/ha at day 547, corresponding to 2.9% of the applied amount. BYI 02960 had a DT_{50} value of 8.3 days, and a DT_{90} value of 279 days.

At Vilobi d'Onyar (Spain), the amount of BYI 02960 determined in 0-10 cm at day 0 was 240 g/ha, which is 96% of the nominal application rate. BYI 02960 declined from 240 g BYI 02960/ha in soil at day 0 to 8.8 g/ha at day 533, corresponding to 3.7% of the applied amount. BYI 02960 had a DT_{50} of 22.6 days, and a DT_{90} value of 215 days.

At Hanscheider Hof (Germany), the amount of BYI 02960 determined in 0-10 cm at day 0 was 229 g/ha, which is 91% of the nominal application rate. BYI 02960 declined from 229 g BYI 02960/ha in soil at day 0 to 20.5 g/ha at day 540, corresponding to 9.0% of the applied amount. BYI 02960 had a DT_{50} of 39.0 days, and a DT_{90} value of 579 days.

In general, BYI 02960 residues remained in the upper 0-20 cm soil layer and only very small amounts (<LOQ) were translocated to a maximum depth of 30 cm. At one site (Vilobi d'Onyar, Spain), BYI 02960 residues just above the LOQ were found at day 13 up in the 20-30 cm soil layer. BYI 02960 dissipated from soil at all test sites with DT_{50} values ranging from 8.3 to 251 days.

The metabolite BYI 02960-DFA appeared in the upper soil layer 0-20 cm in amounts of up to 17.4 g/ha soil. However, the metabolite declined to values of max. 7.9 g/ha soil towards the end of the study (in Burscheid, Germany). An overview of the results for parent compound is given in Table B.8.1.2.2-01.

Table B.8.1.2.2-01 Results synopsis for BYI 02960

Location: Trial No.	Soil type (USDA)	Kinetic model	DT50 [d]	DT90 [d]
Monheim (Germany): 09-2702-01	Sandy loam (0-100 cm)	DFOP	41.0	749

Materials and Methods

Materials

1. Test item: BYI 02960 SL 200;Content of active substance: 200 g/L (soluble concentrate); Specification No: 102000021884, Batch No: 2009-001253

2. Trial locations: The study was conducted at six sites, typical for the ecoregions Southern and Northern Europe (Table B.8.1.2.2-02). At an additional site (Chilly, Northern France) was abandoned because of a heavy rain event of 25 mm occurring 7 hrs after application. The remaining six sites were neither subjected to erosion, flooding nor to run-off. A trial consisted of a treated and an untreated plot at each test site. The control plots were at least 5 m away from the treated plots.

Methods

1. Application: The representative formulation BYI 02960 SL 200, containing 200 g/L BYI 02960 was sprayed once with an application rate of 1.25 L/ha and 300 L water/ha, corresponding to 250 g BYI 02960 per hectare, using a knapsack sprayer.

2. Meteorological data: Air temperature, precipitation including irrigation, and sunshine data were recorded during the field tests. Temperatures were within the range of the long term average for all trial sites.

The overall precipitation was normal in all trials with some exceptions: In trial 09-2702-01 (Monheim, Germany) April and June 2010 were very dry, whereas May, July and August to September 2010 were very wet. In trial 09-2702-02 (Great Chishill, UK) July 2009 was wet but September and October 2009 was dry and April to July 2010 was dry but August 2010 was very wet compared to the long-term average. In trial 09-2702-03 (Burscheid, Germany) May to September 2009 was dry but October to December 2009 wetter compared to the long-term average. In addition, April 2010 was very dry compared to the long-term average. In trial 09-2702-05 (Albaro, Italy) the situation was very special during the trial period: May 2009 and April 2010 was very dry and December 2009 to March 2010, May/June 2010 and August to December 2010 was wet compared to the long-term average. In trial 09-2702-06 (Vilobi d'Onyar, Spain) the summer in 2009 and 2010 was dry compared to the long-term average, except for May 2010 which was wet compared to the long-term average. In trial 09-2702-07 (Hanscheider Hof, Germany) May to September 2009 was dry but October to December 2009 wetter compared to the long-term average, but April 2010 was very dry compared to the long-term average.

3. Sampling and sample processing: Before application samples were taken from control plots to a depth of 10 cm with a soil piercer (Ø 50 mm) and immediately after application from treated plots. All

samples at day 0 consisted of 20 soil cores. All subsequent samplings were performed using a ”Wacker Hammer” (Ø 48 to 50.0 mm). At each sampling interval 20 cores from the treated plots were taken, randomly distributed over the plots. From control plots 10 to 20 soil cores were taken.

In all treated plots the samples were taken to a maximum depth of 100 cm on the following days: 0 (post-application; each 0-10 cm depth), 6-7 (0-30 cm depth), 12-14, 28-30, 60-68 (each 0-50 cm depth), 90-96, 111-128, 177-204, 354-394, 432-478, 533-552 (each 0-100 cm depth) after treatment. From the control plot samples were taken on day 0 before application and 354-394 and 533-552 days after application. In addition, for soil characterisation samples were taken on day -3 (i.e. prior) to day 7 after application from the treated plots to a depth of 100 cm.

The soil samples were deep-frozen within 24 hours, stored and shipped to the test facility BCS, Monheim at maximum -18°C. The cores with the frozen field samples were cut into 10 cm segments. The control samples or the treated samples of each horizon separately (laboratory samples) were milled in a hammer mill and carefully homogenized. A portion of each of the homogenized laboratory samples was transferred into polystyrene boxes (analytical samples) and stored at or below -18 °C until preparation for analysis.

4. Analytical procedure: The modification M001 to the analytical method 01074 was developed for the determination of BYI 02960 and its metabolites in soil. Soil samples of 20 g are extracted in a microwave extractor with 50 mL of a mixture of acetonitrile/water (4/1, v/v). Possible matrix effects of BYI 02960 and its metabolite DFA are eliminated by using an internal standard solution of isotopically labeled reference items. This solution is added to the sample solutions after extraction. Then a subsample is filtrated to remove fine particles of the soil. Identification and quantitation of the test items is done by high performance liquid chromatography using MS/MS detection in the MRM mode (Multiple Reaction Monitoring mode). The method was validated using three different soils. The limit of quantitation (LOQ) for each single analyte is 5.0 µg/kg in soil. The limit of determination (LOD) for each single analyte is 1.5 µg/kg. Recoveries for each fortification level were in an acceptable range (70 - 110%).

Results

Residue Concentrations

The measured initial mean concentrations (n = 4) of BYI 02960 for the test sites were 237 g/ha (Monheim, Germany), 236 g/ha (Great Chishill, UK), 245 g/ha (Burscheid, Germany), 268 g/ha (Albaro, Italy), 240 g/ha (Vilobi d'Onyar, Spain), and 229 g/ha (Burscheid/Hanscheider Hof, Germany) representing 91 to 107 % of the intended dose rate.

Dissipation of BYI 02960 varied at the different test locations. At one site each a very fast and a rather slowly dissipation was observed, whereas the other four sites were similarly in a moderate range of dissipation of the residues. In general the dissipation of BYI 02960 showed a biphasic behavior.

After treatment, BYI 02960 dissipated in a first step very fast within one month followed by a second more slowly step until the end of the study to residue levels of 2.9 to 29.8 % of the total nominal applied amount. Mean residue levels of BYI 02960 reached 35.6 g/ha on day 545 in Monheim, Germany (15% of applied), 70.2 g/ha on day 552 in Great Chishill, UK (29.8% of applied), 17.9 g/ha on day 540 in Burscheid, Germany (7.3% of applied), 7.8 g/ha on day 547 in Albaro, Italy (2.9% of applied), 8.8 g/ha on day 533 in Vilobi d'Onyar, Spain (3.7% of applied), and 20.5 g/ha on day 540 in Hanscheider Hof, Germany (9.0% of applied). In general, BYI 02960 residues remained in the upper 0-20 cm soil layer and only very small amounts could be detected to a maximum depth of 30 cm.

The metabolite DFA appeared in the upper soil layer 0-20 cm in amounts of up to 17.4 g/ha soil. However, the metabolite declined to values of max. 7.9 g/ha soil towards the end of the study.

Kinetics Analysis

Based on the chi^2 error criterion and visual assessment the best fit kinetic model was chosen for the evaluation of the dissipation time. The calculated data are based on the quantifiable residues reported for the entire soil profile in [g/ha], and results are presented in Table B.8.1.2.2-03.

DFOP: Double first-order in parallel

Conclusions

Based on the results it can be concluded that BYI 02960 shows a biphasic degradation behavior under the investigated Northern and Southern European field conditions. BYI 02960 residues remained in the upper 0-20 cm soil layer. Only small amounts below the LOQ could be detected to a maximum depth of 30 cm. At study completion, i.e. 540 days post-application, the remaining BYI 02960 residues in soil corresponded to 2.9 to 29.8% of the applied amount. The calculated DT_{50} of BYI 02960 ranged between 8.3 and 251 days.

In general the field dissipation observed for BYI 02960 residues, i.e. for BYI 02960 and its main soil metabolite DFA, was comparable to that found within the standardized laboratory studies.

Remarks

The field dissipation study is acceptable and the endpoints are reliable. The field study results are not normalized because these are not used for further assessment since the laboratory DT_{50} is smaller

than 60 days and field study is not triggered. For completeness the field study is included in the DAR. The graphs of the fits are available in the study but also not included since the results are not used further. Only the worst case field DT_{50} of 251 days is used for PEC_{soil} calculations (kinetic parameters DFOP, k_1=34.66 and k_2=0.0015 and g =0.27).

B.8.1.2.3 Soil residue studies

No further studies have been performed.

B.8.1.2.4 Soil accumulation studies

No field accumulation studies have been performed as the accumulation of BYI 02960 can be calculated from the degradation data obtained. The results of modelling, considering specific application rates and crops are presented in the PEC_{soil} calculations for the representative uses.

B.8.1.3 Summary route and rate of degradation in soil

Aerobic soil degardation

The route of Flupyradifurone (BYI 02960) degradation in soil was studied using different radiolabel positions, [pyrindinyl-methyl-^{14}C = PYM], [pyridine-2,6-^{14}C = PYR], [furanone-4-^{14}C = FUR] and [ethyl-1-^{14}C = ETH] BYI 02960. The data gathered in the aerobic soil metabolism studies demonstrated that BYI 02960 is degraded in soil.

When using the PYM label in four different European aerobic soils no major metabolites were detected. All formed metabolites were regarded as transient, which was confirmed by the high mineralization rate to $^{14}CO_2$, i.e. up to 58.6% of AR from [PYM-^{14}C] BYI 02960. The portions of not extractable residues (NER) were comparatively low throughout the study (max 16.8% of AR) in case of [PYM-^{14}C] BYI 02960. As minor transformation products BYI 02960-chloro (max. 1.8%) and BYI 02960-des-difluoroethyl (max. 0.4%) were identified (for structures see Figure B.8.1.3-01).

In studies with the FUR label (four European and two US soils) similar results were obtained with regard to the formation of NER (maximum 34.1% of AR) and extensive mineralization to $^{14}CO_2$ (up to 38.9% of AR). With the exception of $^{14}CO_2$ no major metabolites were formed in any of the soils. Degradation, amount of NER as well as of $^{14}CO_2$ formed in sterilised soil was significantly less than in non-sterile soils, indicating a biological component to the degradation/mineralization and formation of non-extractable residues from BYI 02960. Additionally, soil fractionation showed that even with extraction using strong base, BYI 02960 related residues remain bound to the solid (humin) fraction indicating very strong and irreversible binding to soil.

When using [ETH-^{14}C] BYI 02960 in three aerobic soils one major metabolite, identified as difluoroacetic acid (max. 33.9% of AR), and one very minor metabolite was detected and quantified. Again, significant amounts of $^{14}CO_2$ (up to 42.3% AR) were measured, indicating that mineralization of

the test item and/or its metabolites occurred. The maximum amount of NER was relatively low at 17.9% of AR.

The biotransformation of [PYR-^{14}C] BYI 02960 was studied in one aerobic EU and two US soils. The mineralization to $^{14}CO_2$ was significant (max. 57.4, 20.2 and 36.1% of AR) with the formation of minor metabolites in two soils. However, in one US soil, one major metabolite, which was identified as 6-chloronicotinic acid, was formed at maximum of 17.1%. NER formation was in the range of max. 11.3 to 25.5% of AR in the three soils.

Considering the results from laboratory soil metabolism studies the major routes of degradation of BYI 02960, under aerobic conditions, are:

- cleavage of the difluoroethyl group producing difluoroacetic acid (DFA),
- cleavage of the molecule at the pyridinylmethylene bridge with subsequent oxidation to 6-CNA
- mineralization to CO_2 and formation of non-extractable residues.

Degradation under anaerobic conditions and due to photolysis on the soil are not relevant routes for BYI 02960.

Figure B.8.1.3-01 Proposed degradation pathway of BYI02960 in soil

Note: The degradates observed and the maximum values are those for all label positions and soils

The biotransformation of BYI 02960 was studied in several EU and US soils under standardized aerobic and anaerobic laboratory conditions, as well as in a terrestrial field dissipation study performed on six different sites in Europe. BYI 02960 was found to be moderately degradable in aerobic soil under laboratory as well as under field conditions. The clear bi-phasic degradation kinetics indicates that the compound is less available for biotransformation with time, probably due to a time-dependent sorption behavior in soil. The BYI 02960 residues remain stable under anaerobic conditions.

The following Table B.8.1.3-01 summarises the findings in the aerobic laboratory studies. The kinetics data for the metabolite 6-CNA indicate that it is very rapidly degraded in soil with a mean DT_{50} of < 1 week. The metabolite DFA indicated a slightly longer DT_{50}, i.e. it was calculated to be in the range of approx. 2 months.

Anaerobic soil degradation

Three studies investigating the degradation of [PYR-^{14}C], [FUR-^{14}C] and [ETH-^{14}C] BYI 02960 in soils under aerobic, then flooded anaerobic conditions showed that it can be expected that the amounts of BYI 02960 and its major aerobic soil metabolites DFA and 6-CNA remain stable under flooded field conditions. Degradation would be expected to continue according to the proposed overall pathway of degradation of BYI 02960 (see Figure B.8.1.3-01) whenever the conditions in soil turn aerobic again.

Soil photolysis

Phototransformation of [PYM-^{14}C] and [FUR-^{14}C] BYI 02960 was studied on a loam soil. From the results it is concluded that direct phototransformation of BYI 02960 is not regarded as a relevant degradation process in the environment. The soil photolytic DT_{50} of BYI 02960 was 99.6 and 109.3 days.

Field studies

Soil dissipation of BYI 02960 under European field conditions was investigated after application of BYI 02960 SL 200 on bare soil plots at sites in Monheim, Burscheid and Hanscheider Hof (all Germany), Great Chishill (United Kingdom), Albaro (Italy), and Vilobi d'Onyar (Spain). An application was also made in Chilly (Northern France), however the trial was aborted due to heavy rain shortly after application. The sites are located in the ecoregions Northern and Southern Europe.

In general, BYI 02960 residues remained in the upper 0-20 cm soil layer and only very small amounts (<LOQ) were translocated to a maximum depth of 30 cm. At one site (Vilobi d'Onyar, Spain), BYI 02960 residues just above the LOQ were found at day 13 up in the 20-30 cm soil layer. BYI 02960 dissipated from soil at all test sites with DT_{50} values ranging from 8.3 to 251 days.

The metabolite BYI 02960-DFA appeared in the upper soil layer 0-20 cm in amounts of up to 17.4 g/ha soil. However, the metabolite declined to values of max. 7.9 g/ha soil towards the end of the study (in Burscheid, Germany). An overview of the results for parent compound is given in Table B.8.1.3-02.

The field data are not different from the laboratory data in that it does not result in different DT_{50}-values on average. The average DT_{50}-value for the non-normalized field studies is 38.4 days (geometric mean) and 40.0 days (median) compared to the laboratory DT_{50}-values of 72.2 (geometric mean) and 59.7 days (median). A normalization might be conducted, since these values are not required for modelling this is not conducted.

Summary

Freundlich adsorption and desorption constants K_F and K_{OC} of BYI 02960 have been determined in batch equilibrium experiments with four different soils using radiolabeled test substance ([PYM-^{14}C] BYI 02960). The adsorption phase of the study was carried out using pre-equilibrated air-dried soils in 0.01 M aqueous $CaCl_2$ solution with soil/solution ratios of 1:4 for all soils. BYI 02960 was applied at concentrations of nominal 1.0, 0.3, 0.1, 0.03, and 0.01 mg/L. Desorption phase was performed by supplying pre-adsorbed soil samples with fresh 0.01 M aqueous $CaCl_2$ solution for one desorption cycle. Adsorption and desorption took place in the dark at 20 ± 1 °C for 24 hours, each. The test item was stable throughout the study, and the parental mass balance determined for all soils at the highest concentration was in the range of 92.9 - 94.7%.

For key data and results of study see Table B.8.2.1-01.The calculated adsorption constants $K_{f\ (ads)}$ of the Freundlich isotherms for the four test soils ranged from 2.08 to 3.82 mL/g, and the mean $K_{OC(ads)}$ was 93.3 mL/g. The Freundlich exponent 1/n was in the range of 0.8445 to 0.8682, and the mean 1/n was 0.86.

The desorption $K_{F(des)}$ and the normalized $K_{OC(des)}$ values were significantly higher (i.e. 2 times higher) than those obtained for the adsorption phase, indicating that the test item once adsorbed to soil is not readily desorbed.

Materials and Methods

Materials

1. Test Item: Code BYI 02960, CAS no. 951659-40-8 (unlabeled substance); Label position = Pyridinylmethyl-^{14}C] BYI 02960, sample ID BECH 2135; Specific activity: 118.1 µCi/mg (4.37 MBq/mg); Radiochemical and chemical purity: >99% (at beginning of study); The test item was identified by LC-MS/MS).

The test item was dissolved in acetonitrile / Milli-Q-water 1:1 (v/v) (approx. 1 mg/mL) after arrival at the testing facility and stored in a freezer in the dark. Radiopurity of the labeled test item was checked by HPLC analysis before application.

2. Soils: Four soils originating from Germany were used in the batch equilibrium experiments. The pH values of the soil batches were measured in 0.01 M aqueous $CaCl_2$. The soils were air-dried and homogenized by sieving (≤ 2 mm). The detailed parameters of soils are shown in Table B.8.2.1-02.

Methods

1. Experimental conditions: Adsorption and desorption constants of BYI 02960 were determined by batch equilibrium experiments. In pre-tests, the stability of the test substance, an adequate soil/solution ratio as well as appropriate adsorption and desorption equilibration times were determined. Following the preliminary tests the adsorption and desorption phases were carried out for 24 hours using a soil: solution ratio of 1:4.

The adsorption phase of the study was carried out using pre-equilibrated air-dried soils (each 5 g dry weight) in 0.01 M aqueous $CaCl_2$ solution with soil/solution ratios of 1:4 for all soils. [PYM-^{14}C] BYI 02960 was applied at concentrations of nominal 1.0, 0.3, 0.1, 0.03, and 0.01 mg/L. Desorption was performed by supplying pre-adsorbed soil samples with fresh 0.01 M aqueous $CaCl_2$ solution for one desorption cycle. The samples were incubated at constant temperature of 20 ± 1 °C for 24 hours in the dark and continuously agitated using an overhead shaker. Thereafter, the suspensions were centrifuged and the supernatants were analyzed by LSC. Additionally, the pH values of the supernatants were determined.
The experiments were performed in duplicate. The adsorption parameters were calculated using the Freundlich adsorption isotherm.

2. Analytical procedures: In the pre-test the supernatant was analyzed by HPLC. The recovery in HPLC was 97.6% of the injected RA. The limit of quantification (LOQ) of the HPLC analysis was calculated by considering the applied amount of radioactivity and the lowest amount of radioactivity which could be quantified (i.e. LOD = 3 Bq). As an example, for the supernatant phase in case of 0.1 mg/L application rate at soil Laacherhof AXXa a limit of quantification of 1.15% of AR was calculated, corresponding to a LOQ of approx. 1.2 µg/kg.

No degradation product was detected.
In the definitive test the BYI 02960 residue in the supernatant was analyzed by liquid scintillation counting (LSC). After the desorption step, for the calculation of the mass balance, the remaining soil was freeze-dried and combusted. The trapped $^{14}CO_2$ after combustion was measured by LSC. Due to the stability of the test item, the partition of the test item was determined based on the amount of radioactivity measured in the supernatant by LSC.

Results

Mass Balance

In pre-tests, the stability of the test substance, an adequate soil/solution ratio as well as appropriate adsorption and desorption equilibration times were determined, a summary of the recovery after adsorption is presented in Table B.8.2.1-03.

Table B.8.2.1-03 Preliminary study - Recovery of Test Item in Soil after Preliminary Equilibrium Test: Adsorption after incubation for 96 hours calculated as percentage of test item in solution and soil extract.

Soil ID	Laacherhof AXXa (Ax)	Hoefchen am Hohenseh 4a (HF)	Hanscheiderhof (HN)	Dollendorf II DD)
Supernatant [%AR]	51.4	49.4	46.1	34.9
Test item [% of injected]	97.3	97.5	97.7	96.7
Solid phase (ACN extract) [%AR]	45.0	47.5	50.0	60.6
Test item [% of injected]	97.9	98.0	97.7	97.7

Transformation of Test Item

The stability of the BYI 02960 in the test system used was confirmed by performing HPLC analyses prior to the definitive test.

Findings

After 24 hours of equilibration, 34.9 - 52.9%, 36.6 - 52.3%, 38.1- 54.3%, and 50.2 - 66.4% of the applied test item were adsorbed in soils Laacher Hof AXXa, Hoefchen am Hohenseh 4a, Hanscheiderhof, and Dollendorf II, respectively. The adsorption behavior of BYI 02960 in the concentration range of two orders of magnitude (i.e. from 0.01 to 1.0 mg/L) was accurately described for all soils with the Freundlich equation (see Table B.8.2.1-07). The correlation coefficient of the individual isotherms was 0.9988 to 0.9999. The calculated adsorption constants Kf (ads) of the Freundlich isotherms ranged from 2.077 mL/g to 3.822 mL/g. The Freundlich exponents 1/n were in the range of 0.8445 to 0.8682, indicating that the concentration of the test item affected the adsorption behavior in the examined concentration range.

In general, the organic matter in soil, determined as organic carbon content, is the most important part to bind organic chemicals. Therefore, the adsorption coefficients Kf (ads) are correlated with the organic carbon content of the soil, in order to get a comparability of the adsorption behavior in different soils. For BYI 02960 the calculated KOC(ads) values varied between 74.9 and 107.0 mL/g (mean: 93.3 mL/g.

At the end of the desorption phase, 31.5 - 44.4%, 33.8 - 43.4%, 31.0 - 39.9%, and 22.0 - 31.9% of the initially adsorbed amount was desorbed in soils Laacher Hof AXXa, Hoefchen am Hohenseh 4a, Hanscheiderhof, and Dollendorf II, respectively. The calculated desorption constants K_f (des) of the Freundlich isotherms for the four test soils ranged from 4.115 - 7.056 mL/g. The $K_{OC(des)}$ values of the soils ranged from 138.4 - 236.7 mL/g (mean: 188.9 mL/g). Thus, the $K_{OC(des)}$ values were significantly (1.8 to 2.2 times) higher than the $K_{OC(ads)}$ values, indicating a strengthened binding of the test item once adsorbed to the soil.

Conclusions

BYI 02960 can be classified as intermediate mobile for adsorption and low mobile for desorption. For a compilation of results see Table B.8.2.1-07.

Remarks

The results of the adsorption desorption study for BYI 02960 is acceptable and reliable. Flupyradifurone does no dissociate in aqueous solutions in the pH-range 1< pH <12 and hence there is no reason to expect a pH dependence of the sorption. The range of tested pH values is about two units and reflects typical agricultural soils. The Kom values seem to decrease with higher pH values, however, a statistical significant correlation could not be determined (e.g. by the Kendall test included in the German input decision tool). Moreover the coefficient of variation for the resulting Kom values accounts for 20 % and indicates a very good determination of this parameter. Looking at the Kf dependence on pH it becomes also clear that the magnitude of sorption is not dependent on pH. The endpoints will be used for risk assessment.

purity	:	radiochemical purity > 99%	acceptability	:	**acceptable**

Summary

Freundlich adsorption and desorption constants K_F and K_{OC} of BYI 02960 have been determined in batch equilibrium experiments with two different soils using radiolabeled test substance ([PYM-^{14}C] BYI

02960). The adsorption phase of the study was carried out using pre-equilibrated air-dried soils in 0.01 M aqueous $CaCl_2$ solution with soil/solution ratios of 1:1 soil Sanger and 1/2 for soil Springfield. BYI 02960 was applied at concentrations of nominal 1.0, 0.3, 0.1, 0.03, and 0.01 mg/L. Desorption phase was performed by supplying pre-adsorbed soil samples with fresh 0.01 M aqueous $CaCl_2$ solution for one desorption cycle. Adsorption and desorption took place in the dark at 20 ± 1 °C for 24 hours, each. For the highest concentration, two additional desorption cycles were performed with 24 hours equilibration time each. The test item was stable throughout the study, and the parental mass balance determined for all soils at the highest concentration was in the range of 93.4 - 94.4%. For key data and results of study see Table B.8.2.1-08.

The calculated adsorption constants $K_{f\ (ads)}$ of the Freundlich isotherms for the two test soils were 0.597 and 2.512 mL/g, and the mean $K_{OC(ads)}$ was 1.554 mL/g. The Freundlich exponent 1/n was 0.8505 and 0.9021 (mean 0.8763).

The desorption $K_{f\ (des)}$ and the normalized $K_{OC(des)}$ values were significantly (i.e. 2.0 and 3.6 times) than those obtained for the adsorption phase, indicating that the test item once adsorbed to soil is not readily desorbed.

Table B.8.2.1-08 Key data and results of study

Soil origin	Sanger, CA, USA	Springfield, NE, USA
Soil type (USDA)	Sandy loam	Silt loam
pH (aqueous $CaCl_2$ solution)	6.8	6.5
Organic carbon [%]	0.7	1.9
$K_{f\ (ads)}$ [mL/g]	0.597	2.512
1/n	0.9021	0.8505
$K_{oc(ads)}$ [mL/g]	**85.2**	**132.2**

(Arithmentic mean $K_{OC(ads)}$: 108.7 mL/g and 1/n 0.8363)

Material and Methods

Materials

1. Test Item: Code BYI 02960, CAS no. 951659-40-8 (unlabelled substance); Label position = [Pyridinylmethyl-^{14}C] BYI 02960, sample ID MERVP017-SS; The test item was identified by HPLC-MS/MS; Specific activity: 118.1 µCi/mg (4.37 MBq/mg); Radiochemical and chemical purity: >99% (at beginning of study)

The test item was dissolved in acetonitrile after arrival at the testing facility and stored in a freezer in the dark. Radiopurity of the labeled test item was checked by HPLC analysis before application.

2. Soils: Two soils originating from the USA were used in the batch equilibrium experiments. The pH values of the soil batches were measured in 0.01 M aqueous $CaCl_2$. The soils were air-dried and homogenized by sieving (≤ 2 mm). The detailed parameters of soils are shown in Table B.8.2.1-09.

Methods

1. Experimental conditions: Adsorption and desorption constants K_{OC} of BYI 02960 were determined for two soils (see Table B.8.2.1-09) with batch equilibrium experiments using [PYM-^{14}C] BYI 02960. Preliminary tests were performed prior to the definitive test in order to optimize the test conditions.

The adsorption phase of the study was carried out using pre-equilibrated air-dried soils (each 5 g dry weight) in 0.01 M aqueous $CaCl_2$ solution with soil/solution ratios of 1:4, 1:2 and 1:1 for the soils. BYI 02960 was applied at concentrations of nominal 1.0, 0.3, 0.1, 0.03, and 0.01 mg/L. Desorption phase was performed by supplying pre-adsorbed soil samples with fresh 0.01 M aqueous $CaCl_2$ solution for one desorption cycle. The samples were incubated at constant temperature of 20 ± 1 °C for 24 hours in the dark. Thereafter, the suspensions were centrifuged and the supernatants were analyzed by LSC. Additionally, the pH values of the supernatants were determined. The experiments were performed in duplicate. The adsorption parameters were calculated using the Freunlich adsorption isotherm.

2. Analytical procedures: In the pre-test the supernatant was analyzed by HPLC. The recovery in HPLC was 97.4% of the injected radioactivity. The limit of quantification (LOQ) of the HPLC analysis was calculated by considering the applied amount of radioactivity and the lowest amount of radioactivity which could be quantified (LOD). The limit of detection (LOD) was set to 150 dpm, i.e. 0.3% of applied radioactivity, deduced from the chromatograms of the parental mass balance samples (supernatant, 96 hours equilibration time, highest concentration nominal 1.0 mg/L). The LOQ (limit of quantification) was set to three times the LOD, i.e. 450 dpm or 0.9% of applied radioactivity.

In the definitive test the BYI 02960 residue in the supernatant was analyzed by liquid scintillation counting (LSC). After the desorption step, for the calculation of the mass balance, the remaining soil was freeze-dried and combusted. The trapped $^{14}CO_2$ after combustion was measured by LSC.

Transformation of Test Item

The stability of the BYI 02960 in the test system used was confirmed by performing HPLC analyses prior to the definitive test.

Findings

The adsorption behavior of BYI 02960 in the concentration range of two orders of magnitude (i.e. from 0.01 - 1.0 mg/L) was accurately described for all soils with the Freundlich equation (for summary of results see Table B.8.2.1-14). The correlation coefficient of the individual isotherms was 0.9993 and 0.9995. The calculated adsorption constants $K_{f\ (ads)}$ of the Freundlich isotherms were 0.597 and 2.512 mL/g (mean: 1.554 mL/g). The Freundlich exponents 1/n were 0.8505 and 0.9021 (mean: 0.8763), indicating that the concentration of the test item affected the adsorption behavior in the examined concentration range.

In general, the organic matter in soil, determined as organic carbon content, is the most important part to bind organic chemicals. Therefore, the adsorption coefficients $K_{f\ (ads)}$ were correlated with the organic carbon content of the soil, in order to get a comparability of the adsorption behavior in different soils. For BYI 02960 the calculated $K_{OC(ads)}$ values were 85.2 and 132.2 mL/g (mean: 108.7 mL/g).

At the end of desorption phase, 23.7-29.5 % and 13.2-23.1 % of the initially adsorbed amount was desorbed in soils Sanger and Springfield, respectively. The calculated desorption constants $K_{f\ (des)}$ of the FREUNDLICH isotherms for the two test soils were 2.143 and 5.096 mL/g (mean: 3.620 mL/g). The $K_{OC(des)}$ values of the soils were 268.2 and 306.2 mL/g (mean: 287.2 mL/g).

The $K_{OC(des)}$ values were significantly (2.0 and 3.6 times) higher than the $K_{OC(ads)}$ values, indicating a strengthened binding of the test item once adsorbed to the soil.

Remarks

The results of the adsorption desorption study for BYI 02960 is acceptable and reliable. The endpoints will be used for risk assessment.

STUDY IIA, 7.4.1/03

Characteristics

reference	:	Menke, U., 2011	study type	:	time dependent sorption
year of execution	:	2007-2009	incubation time	:	120 days
GLP statement	:	yes	nominal concentration	:	0.53 mg / kg soil
guideline	:	OECD 307 (2002) US EPA, OPPTS 835.4100 (2008) OECD106 (2001)	temperature	:	20°C
test substance	:	[pyridinylmethyl-^{14}C] BYI 02960	$K_F$oc	:	see results
purity	:	> 99%	1/n	:	see results
soils	:	four soils; sandy loam, silt loam, loam, clay loam	acceptability	:	**acceptable**

Summary

The biotransformation and time dependent sorption of [pyridinylmethyl-^{14}C] BYI 02960 was studied in four European soils: Laacher Hof AXXa (AX), Höfchen am Hohenseh (HF), Hanscheiderhof Plot 611 (HN), and Dollendorf II (DD) for a maximum period of 120 days under aerobic conditions in the dark at ca. 20 °C and 55% WHC_{max} (max. water holding capacity). BYI 02960 was applied at the nominal rate of 0.53 mg/kg soil, which is equivalent to 200 g/ha field application rate (see study IIA.7.1.1/01)

At each sampling date the soil samples were shaken for 24 hours with 400 mL $CaCl_2$-solution in order to measure the time-dependent desorption of the test item. Subsequently they were extracted by shaking at ambient temperature and in a microwave at 70 °C with acetonitrile/water mixtures, and the BYI 02960 residues were analyzed and quantified by TLC with HPLC as the confirmatory method.The degradation and metabolism part of the study was summarized earlier (see IIA 7.1.1/01), this summary only considers results relevant to the assessment of time dependent sorption.

At the beginning of the study (DAT-0; equivalent to approximately two hours) the distribution coefficient values R_{TDS} were 1.46, 1.91, 3.35 and 4.66 mL/g for soils AX, HF, HN and DD, respectively. Depending on the ageing time, these values increased with time until the end of the study to 6.50, 5.64, 10.78 and 12.16 mL/g for the four soils indicating a significant increase of sorption with time. Based on results from the ageing time of 120 days, the R_{TDS} values increased by a factor of 4.4, 2.9, 3.2 and 2.6 (mean of all four soils = 3.3).

Materials and Methods

Materials

1. Test Item: Flupyradifurone: Code = BYI 02960; Label PYM = [Pyridinyl-methyl-^{14}C] BYI 02960 (sample ID: BECH 2123); Specific activity 4.37 MBq/mg; Radiochemical purity: >99% (acc. radio-HPLC and -TLC); Chemical purity: >99% (HPLC, UV detection at 210 nm); Identity and purity of test item in the application solution were confirmed.

2. Soil: The time-dependent sorption of BYI 2960 was studied in four different soils (for physico-chemical properties (see study IIA, 7.1.1/01). These soils are representative for agricultural use areas as required by the guidelines and cover a representative range of physico-chemical properties. Other details were summarized earlier (see IIA, 7.1.1/01).

Methods

See for summary of study IIA, 7.1.1/01. In addition the changes of the sorption parameter R_{TDS} (equivalent to K_d) of BYI 02960 affected by a preceding ageing period in soil were investigated by time-dependent desorption experiments. This additional test was designed in analogy to a "batch equilibrium" study. The soils incubated with the test item were shaken for 24 hours with 400 mL 0.1 M $CaCl_2$ solution, i.e. a soil to solution ratio of 1:4 was applied, which was derived from the respective batch equilibrium adsorption/desorption study (see study IIA, 7.1.1/01).

After centrifugation, the distribution of the test item between supernatant and soil was determined by means of LSC. For TLC analysis, the extracts were not processed further. About 20 Bq of the extracts were spotted per cm lane onto silica plates. For HPLC, the desorption solution ($CaCl_2$ extract) was analyzed directly as well (designation: D).

The R_{TDS} values (ratio time-dependent sorption, equivalent to K_d values) were calculated by:

$$R_{TDS} = \frac{concentration\ of\ test\ item\ in\ soil\ extract\ [\frac{\mu g}{g}]}{concentration\ of\ test\ item\ in\ CaCl_2\ solution\ [\frac{\mu g}{mL}]} = \frac{c_{extr}}{c_{des}}$$

For basic data including recovery and degradation data see summary under study IIA, 7.1.1/01.

Findings

The results of desorption measurements affected by the ageing period are presented in Table B.8.2.1-15. The R_{TDS} values were 1.46, 1.91, 3.35 and 4.66 mL/g for soils AX, HF, HN and DD, respectively, at the beginning of the study (DAT-0; equivalent to approximately two hours). With time of ageing in soil, these values increased until the end of the study to 6.50, 5.64, 10.78 and 12.16 mL/g for the four soils. Based on these results during an ageing time of 120 days, the mean R_{TDS} value increased by a factor of 4.4, 2.9, 3.2 and 2.6 (mean of all four soils = 3.3).

Conclusions

Major Outcomes of Study

During the ageing period of 120 days a clear increase of the distribution coefficient R_{TDS} became apparent. Based on the results of an ageing time of 120 days, the R_{TDS} values increased by a factor of 2.6 to 4.4 (mean of all four soils = 3.3).

Significance of Results to Environmental Behavior of BYI 02960

The current laboratory study demonstrated that whenever BYI 02960 has time to age in soil it is much less susceptible to leaching. Parameters for exposure modelling can be derived from the study as decribed in study IIA, 7.4.1/04.

Remarks

See study IIA, 7.4.1/04

This report is a supplement to study IIA, 7.4.1/03 and evaluates the study to derive input parameters for implementation in environmental exposure modelling.

Summary

Experimental sorption data of BYI 02960 on four soils (see report IIA 7.1.1/01). BYI 02960 was incubated at initial concentrations of about 0.5 mg/kg for 120 d at constant soil moisture (55% MWHC) and 20°C in a number of four soils with varying properties. After the respective incubation period, BYI 02960 was first desorbed with aqueous $CaCl_2$ to derive kinetic sorption parameters via curve fitting. These parameters constitute the prerequisite to adequately address time-dependent sorption processes in regulatory exposure modelling. The kinetic sorption was evaluated according to the model of Boesten et al. (1989) implemented in the groundwater leaching models PEARL and FOCUS-PELMO (FOCUS, 2009).

Up to the end of the incubation period (120 days) the (desorption) $K_{d,oc}$ (defined as $R_{TDS,OC}$: ratio of concentration adsorbed to soil and in solution) increased by a factor of 4.4 at the maximum (see study IIA, 7.4.1/03 and Table B.8.2.1-16) indicating kinetically controlled sorption processes.

The experimental raw data were pre-processed to calculate the concentration in the $CaCl_2$ desorption solution, and the total mass. These data were used to fit the kinetic-sorption model using PEARLNEQ. The evaluation showed that the experimental data could be well described by the kinetic-sorption model, with excellent fits and reliable parameter estimates. The inferred parameters were the desorption rate constant k_{des} [1/d], the ratio between the Freundlich coefficients in the non-equilibrium and in the equilibrium compartment f_{ne} [-], the degradation half-life in the equilibrium compartment DT_{50_eq} [d], the organic matter normalized distribution coefficient in the equilibrium compartment K_{om_eq} [L/kg], and the initial total mass in the system M_{ini} [µg]. The corresponding values for all four soils are shown in Table B.8.2.1-16.

The kinetic desorption rate constant $k_{_des}$ indicates a time scale of about 22 d, calculated as "pseudo half-life" for the exchange between equilibrium and non-equilibrium domain.

Values for $f_{_ne}$ in the range of 0.387 – 0.779 indicate that the kinetically controlled "sorption capacity" is in the range of 39% - 78%, and accounts on average for about 58% of the instantaneous "sorption capacity". The DT_{50_eq} representing degradation in the equilibrium domain was on average (geomean) 58 d suggesting moderate degradation during the laboratory study.

Materials and Methods

Materials

1. Test Item: See study IIA, 7.1.1/01

2. Data: For basic data see study IIA, 7.1.1/01. In the present study the Freundlich exponent 1/n of the batch adsorption of the four soils was taken from study IIA, 7.4.1/01, see Table B.8.2.1-07.

Methods

Experimental sorption data of BYI 02960 (Flupyradifurone) on four soils were used to derive kinetic sorption parameters via curve fitting. These parameters constitute the prerequisite to adequately address time-dependent sorption processes in regulatory exposure modelling. The kinetic sorption was evaluated according to the model of Boesten et al. (1989) implemented in the groundwater leaching models PEARL and FOCUS-PELMO (FOCUS, 2009).

The sorption is described as rate limited between an instantaneous equilibrium and a non-equilibrium domain. Degradation of the compound occurs only in the equilibrium domain including a dissolved and an equilibrium sorbed phase. If kinetic sorption is relevant, a part of the substance is sorbed in the non-equilibrium domain where no degradation is assumed. Therefore, considering both domains the apparent degradation of the substance is lower than the observed degradation in the equilibrium domain only. Thus, the degradation curve of the total substance may show a bi-phasic behaviour as a slowdown of total degradation results from the increasing fraction of substance being sorbed in the non-equilibrium domain.

The experimental raw data were pre-processed to calculate the concentration in the $CaCl_2$ desorption solution, and the total mass. These data were used to fit the kinetic-sorption model using PEARLNEQ program (Version 5; Boesten et al. 2007).

Results

The evaluation showed that the experimental data could be well described by the kinetic-sorption model, with excellent fits and reliable parameter estimates. The inferred parameters were the desorption rate constant $k_{_des}$ [1/d], the ratio between the Freundlich coefficients in the non-equilibrium and in the equilibrium compartment $f_{_ne}$ [-], the degradation half-life in the equilibrium compartment

DT_{50_eq} [d], the organic matter normalized distribution coefficient in the equilibrium compartment K_{om_eq} [L/kg], and the initial total mass in the system $M_{_ini}$ [µg].

Results of the curve fitting procedure used to derive optimized kinetic sorption parameters for BYI 02960 are shown in Table B.8.2.1-16. The kinetic desorption rate constant $k_{_des}$ indicates a time scale of about 22 days, calculated as "pseudo half-life" for the exchange between equilibrium and non-equilibrium domain. Values for $f_{_ne}$ in the range of 0.387 - 0.779 indicate that the kinetically controlled "sorption capacity" is in the range of 39 - 78%, and accounts on average for about 58% of the instantaneous "sorption capacity". The DT_{50_eq} representing degradation in the equilibrium domain was on average (geomean) 58 days suggesting moderate degradation during the laboratory study.

Table B.8.2.1-16 Estimated parameters of the kinetic-sorption model for all soils

Soil	$M_{_ini}$ [µg]	K_{om_eq} [L/kg]	DT_{50_eq} [d]	$K_{_des}$ [1/d]	$F_{_ne}$ [-]
Laacher Hof AXXa (AX)	44.5	40.3	57.3	0.031	0.779
Dollendorf II (DD)	46.0	39.3	50.1	0.029	0.470
Hanscheider Hof (HN)	46.0	62.8	86.6	0.032	0.683
Hoefchen am Hohenseh (HF)	47.7	43.6	45.7	0.033	0.387
Arithmetic mean	**46.1**	**46.5**			**0.580**
Geometric mean			**58.0**	**0.031**	

The fits between experimental and modelled data were visually good. The statistical parameters also indicate a sufficient goodness of fit. The χ^2 statistics indicate a very good fit with values ranging from 3.1 for the AXXa soil to 1.6 for the Hoefchen soil (Table B.8.2.1-17). Relative standard error (RSE) values were generally small and never exceeded 0.25 implying parameter estimates with a high confidence.

Table B.8.2.1-17 χ^2 statistics and RSE values for the parameter estimates of the kinetic sorption model

Soil		RSE				
	χ^2	M_ini	Kom_eq	DT50_eq	k_des	f_ne
AX	3.12	0.014	0.121	0.041	0.133	0.105
DD	1.74	0.008	0.026	0.018	0.090	0.057
HN	1.93	0.009	0.038	0.031	0.090	0.061
HF	1.62	0.007	0.042	0.017	0.099	0.064

Conclusion

The time-dependent sorption data received for BYI 02960 constitute the prerequisite to adequately address the obvious TDS process in higher tier regulatory modelling, e.g. related to a potential groundwater contamination.

Remarks

It is not reported whether the optimisation was done using different starting values of the parameters. Beulke and van Beinum (2012)[1] advise to do so and to report the results of these different optimisations. However, this case seems a well posed optimisation problem, so the RMS does not expect that different starting values would lead to very different optimised parameter values.

Beulke and van Beinum (2012) also advise to calculate the apparent sorption coefficient for each measurement and plot it as a function of time and assess is visually. This was not done by the authors. Since, this case seems a well posed optimisation problem The RMS does not expect that adding this assessment would lead to rejection of the optimised parameter values.

Furthermore, Beulke and van Beinum (2012) advise to compare the optimised $K_{om,EQ}$ with the $K_{om,EQ}$ value that is calculated from the measured total mass and the concentration in the liquid phase at DAT0 ($K_{om,0}$). A difference of more than 20% between the fitted $K_{om,EQ}$ and the $K_{om,0}$ is considered not acceptable. This check was not done by the authors. Since, this is a very important criterion the RMS decided to do this calculation and found that the difference between fitted $K_{om,EQ}$ and the $K_{om,0}$ was below 20% for all four soils.

The RMS concludes that the fitting of the kinetic model to the data from the time dependent sorption study was performed adequately and that its resulting optimised parameter values are suitable for use in regulatory assessments.

STUDY IIA, 7.4.1/05

Characteristics

This report is a supplement to study IIA, 7.4.1/02 and study IIA, 7.4.1/03 and evaluates the study to derive input parameters for implementation in environmental exposure modelling according to the draft guidance document on time dependent sorption (Beulke and van Beinmum, 2012). The results from study IIA, 7.4.1/03 are replaced by the results obtained in this study.

[1] Beulke, S. and van Beinum, W. (2012). Guidance on how aged sorption studies for pesticides should be conducted, analysed and used in regulatory assessments. The Food and Environment Research Agency. Sand Hutton, YO41 1LZ, UK.

The objective of this study is to describe the kinetic processes which control the sorption of Flupyradifurone by means of a kinetic-sorption model according to Boesten et al. (1989) [2] and to derive kinetic-sorption parameter values which can be used in higher-tier evaluation studies and exposure assessments. The dependence of the parameter estimates on starting values for desorption rate constant (k_des) and f_ne, the ratio between the Freundlich coefficients in the non-equilibrium and in the equilibrium compartment, was also investigated. The evaluation was conducted to comply with the currently available draft guidance on evaluating such studies (Beulke and van Beinmum, 2012).

Summary

The study reflects thorough evaluation of the magnitude of the kinetic sorption characteristics of Flupyradifurone resulted in 4 robust parameter sets, that serve requirements laid down by Beulke and van Beinum (2012). Kinetic sorption parameters for 4 soils were derived and showed virtually no dependence on the initial values of k_des and f_ne and the corresponding parameter estimates for Kom_eq did not deviate by more than 15 % from the matching value calculated at DAT0.

The summary of the results is given in Table B.8.2.1-18. Desorption rate constant *k_des* corresponds to 22.4 d ,the half-life for the exchange process between equilibrium and non-equilibrium domains. Values from 0.3875 – 0.7808 for *f_ne* indicate that kinetic sorption capacity is in the range of 39 - 78 % of the instantaneous sorption capacity. The *Kom_eq* is derived to be 47.5 L/kg on average and the degradation half-life in the equilibrium domain is 57.9 d, .

Table B.8.2.1-18 Kinetic sorption parameter optimization results, including their RSE in brackets for the 4 soils. The most appropriate parameter set out of 4 starting value combinations are given.

Soil	M_ini [µg]	k_des [1/d]	f_ne [-]	DT50_eq [d]	Kom_eq [L/kg]	Chi²-err [%]
AXXa	44.6 (0.0144)	0.0306 (0.1319)	0.7808 (0.1066)	57.1 (0.0397)	40.7 (0.1188)	9.68
Dollendorf	46.0 (0.0077)	0.0282 (0.0906)	0.4738 (0.0566)	49.9 (0.0181)	39.9 (0.0262)	4.90

Hoefchen	47.7 (0.0071)	0.0333 (0.0995)	0.3875 (0.00654)	45.6 (0.0173)	46.1 (0.0419)	3.32
	average		**0.5821**		**47.5**	
	geometric mean	**0.0309**		**57.9**		

Method (hardware software)

Parameter estimates for the kinetic sorption processes were obtained by curve fitting employing the PEARLNEQ (Version 5, Boesten et al., 2007) program that integrates the kinetic sorption model

[2] Boesten, J.J.T.I., van der Pas, L.J.T. and Smelt, J.H. (1989): Field test of a mathematical model for non-equilibrium transport of pesticides in soil. Pesticide Science, 25, 187-203.

implemented in PEARL and the optimization package PEST (Doherty, 2005). In brief, the PEARLNEQ program is run consecutively by PEST until the criteria for the goodness of fit are achieved. The underlying optimization method follows least-squares and Gauss-Marquardt-Levenberg algorithm employing inverse weights to achieve a relative error model. The model is fitted against the total mass of pesticide in soil, M_tot [µg], and the concentration in the liquid phase of the equilibrium domain, C_liq [µg/L].

The PEARLNEQ summary output files including a listing of observed and predicted values, the initial and optimized parameters and their 95% confidence interval.

Fitting procedure

The above described model was fitted to the observed replicate data using the PEARLNEQ program as described in Beulke and van Beinum (2012).

- Following parameters were optimized: M_ini, k_des, f_ne, DT50_eq, Kom_eq. The corresponding 1/n value was taken from an accompanying batch sorption study including the same soils, albeit from different batches
- Optimization settings for PEST were set accordingly similar to the guidance provided in Beulke and van Beinum (2012)
- a log-normal distribution for k_des and f_ne was assumed
- A varying timestep was implemented
- A relative error model was assumed employing weights calculated as the inverse of the measurements
- Observed values at t < 48 h of incubation were omitted from the curve fitting.

A number of four starting value combinations for the parameters k_des and f_ne were used to derive a robust parameter set for each individual soil as recommended in Beulke and van Beinum (2012).

Table B.8.2.1-19 Starting values for f_ne and k_des

Version	f_ne	k_des
1	0.2	0.004
2	0.2	0.05
3	1.5	0.004
4	1.5	0.05

Goodness of fit

Three criteria for the assessment of the goodness of the fit are proposed by Beulke and van Beinum (2012).

1. A visual assessment of both the total mass and the liquid phase concentration as well as the apparent Kd over time

2. A residual assessment

3. χ2-test.

Additionally, the fitted Kom_eq is required to be within ±20% of the Kom_eq value calculated from the measurements of total mass and liquid phase concentration at DAT0.

Results

Soil AXXa

The equilibrium model assuming no kinetic sorption did not deliver a visually acceptable fit (Figure B.8.2.1-01), particularly the liquid phase concentration was describe very poorly. Therefore, it is appropriate to assume kinetic sorption process and to evaluate its magnitude.

Figure B.8.2.1-01 **Equilibrium model fit to AXXa soil data.**
Total mass depicted at top and liquid phase concentration at bottom.

Table B.8.2.1-20 **Parameter optimization for soil AXXa, using 4 different starting sets for *f_ne* and *k_des*, Chi2-error %and sum of RSE (single rel. standard error RSE in brackets); most appropriate parameter set given in bold**

Version	M_ini [µg]	k_des [1/d]	f_ne [-]	DT50_eq [d]	Kom_eq [L/kg]	Chi^2-err [%]	Sum of RSE
1	44.6 (0.0144)	0.0306 (0.1325)	0.7817 (0.1065)	57.1 (0.0340)	40.6 (0.1191)	9.69	0.4125
2	44.6 (0.0144)	0.0306 (0.1325)	0.7817 (0.1065)	57.1 (0.0340)	40.6 (0.1190)	9.69	0.4125
3	**44.6 (0.0144)**	**0.0306 (0.1319)**	**0.7808 (0.1066)**	**57.1 (0.0397)**	**40.7 (0.1188)**	**9.68**	**0.4115**
4	44.6 (0.0144)	0.0306 (0.1325)	0.7818 (0.1065)	57.1 (0.0340)	40.6 (0.1190)	9.69	0.4124

The optimization results for the 4 starting value combinations of *k_des* and *f_ne* are given in Table B.8.2.1-20. From the numbers it is clear that there are only very minor differences between the four estimations and thus a robust parameter set for the kinetic sorption magnitude in soil AXXa can be derived. By means of the Chi2-error percentage and the sum of RSE values the parameter set from version 3 appears as the most appropriate one and will be discussed in more details in the following.

The model fit described by parameter starting value combination 3 is depicted in detail in Figure B.8.2.1-02 - Figure B.8.2.1-04. Total mass dissipation and liquid phase concentration are represented very well by the model fit (Figure B.8.2.1-02), the residuals indicate a good representation of data (Figure B.8.2.1-03) and the apparent Kd value over time is reasonably well estimated by the model parameters (Figure B.8.2.1-04). Clearly, the kinetic sorption model is a better representation of the measured data than the equilibrium model (c.f. Figure B.8.2.1-01). Additionally, the parameter estimates are derived with low RSE values well below the proposed threshold of 0.4, f_ne is <10 and k_des < 0.5. The difference to the Kom_eq calculated from data at DAT0 accounts for only 15% and is thus also within the range of acceptable deviation (Beulke and van Beinum, 2012).

Figure B.8.2.1-04 Measured and fitted apparent Kd value (top) and distribution of mass between equilibrium and non-equilibrium sorption domain (bottom) in soil AXXa and for starting value combination version 3

Soil Dollendorf

The equilibrium model fit without kinetic sorption to the data for the soil Dollendorf is shown in Figure B.8.2.1-05. While the total mass is quite well predicted the liquid phase concentration is not very well represented. Therefore, a systematic evaluation of the kinetic sorption parameters for the soil Dollendorf was performed.

Figure B.8.2.1-05 Equilibrium model fit to Dollendorf soil data.
Total mass depicted at top and liquid phase concentration at bottom.

Table B.8.2.1-21 Parameter optimization for soil Dollendorf, using 4 different starting sets for f_ne and k_des, Chi2-error %and sum of RSE (single rel. standard error RSE in brackets); most appropriate parameter set given in bold

Version	M_ini [µg]	k_des [1/d]	f_ne [-]	DT50_eq [d]	Kom_eq [L/kg]	Chi²-err [%]	Sum of RSE
1	**46.0 (0.0077)**	**0.0282 (0.0906)**	**0.4738 (0.0566)**	**49.9 (0.0181)**	**39.9 (0.0262)**	**4.90**	**0.1992**
2	46.0 (0.0077)	0.0282 (0.0913)	0.4735 (0.0567)	50.0 (0.0183)	40.0 (0.0270)	4.92	0.2010
3	46.0 (0.0077)	0.0282 (0.0913)	0.4735 (0.0567)	50.0 (0.0183)	39.9 (0.0270)	4.91	0.2009
4	46.0 (0.0077)	0.0282 (0.0910)	0.4737 (0.0567)	50.0 (0.0184)	39.9 (0.0272)	4.92	0.2009

The optimization results for the four starting value combinations of k_des and f_ne are given in Table B.8.2.1-21. There are only very minor differences between the four estimations and thus a robust parameter set for the kinetic sorption magnitude in the Dollendorf soil can be derived. By means of the Chi2-error percentage and the sum of RSE values the parameter set from version 1 appears as the most appropriate one and will be discussed in more details in the following.

The model fit described by parameter starting value combination 1 is depicted in detail in Figure B.8.2.1-06 - Figure B.8.2.1-08. Total mass dissipation and liquid phase concentration are represented very well by the model fit (Figure B.8.2.1-06). Also the residuals indicate a good representation of data (Figure B.8.2.1-07) and the apparent Kd value over time is very well estimated by the model parameters and the corresponding fit (Figure B.8.2.1-08). Clearly, the kinetic sorption model is a better representation of the measured data than the equilibrium model (c.f. Figure B.8.2.1-05). Additionally, the parameter estimates are derived with very low RSE values well below the proposed threshold of 0.4, f_ne is <10 and k_des < 0.5 (c.f. Table B.8.2.1-21). The difference to the Kom_eq calculated from data at DAT0 accounts for only 1.5% and is thus also within the range of acceptable deviation (Beulke and van Beinum, 2012).

Soil Hanscheider Hof

The equilibrium model fit assuming no kinetic sorption to data for the soil Hanscheider Hof is depicted in Figure B.8.2.1-09. The fit indicates that the equilibrium model does not represent the data very well. Both the total mass and the liquid phase concentration are not very well represented by the model fit. An evaluation of the kinetic sorption magnitude is therefore warranted.

Figure B.8.2.1-09 Equilibrium model fit to Hanscheider Hof soil data.
Total mass depicted at top and liquid phase concentration at bottom.

Table B.8.2.1-22 Parameter optimization for soil Hanscheider Hof, using 4 different starting sets for f_ne and k_des, Chi2-error %and sum of RSE (single rel. standard error RSE in brackets); most appropriate parameter set given in bold

Version	M_ini [µg]	k_des [1/d]	f_ne [-]	DT50_eq [d]	Kom_eq [L/kg]	Chi^2-err [%]	Sum of RSE
1	46.0 (0.0090)	0.0316 (0.0906)	0.6865 (0.0610)	86.4 (0.0313)	63.4 (0.0381)	4.28	0.2300
2	46.0 (0.0089)	0.0315 (0.0913)	0.6865 (0.00609)	86.5 (0.0317)	63.4 (0.0389)	4.29	0.2317
3	**46.0 (0.0090)**	**0.0316 (0.0906)**	**0.6865 (0.00610)**	**86.4 (0.0313)**	**63.4 (0.0380)**	**4.28**	**0.2299**
4	46.0 (0.0090)	0.0316 (0.00906)	0.6865 (0.0610)	86.4 (0.0313)	63.4 (0.0381)	4.28	0.2300

The optimization results for the four starting value combinations of *k_des* and *f_ne* are given in Table B.8.2.1-22. There are only very minor differences between the four estimations and thus a robust parameter set for the kinetic sorption magnitude in the Hanscheider Hof soil can be derived. By means

of the Chi2-error percentage and the sum of RSE values the parameter set from version 3 appears as the most appropriate one and will be discussed in more details in the following.

The model fit described by parameter starting value combination 3 is shown in detail in Figure B.8.2.1-10 -Figure B.8.2.1-12. Total mass dissipation and liquid phase concentration are represented very well by the model fit (Figure B.8.2.1-10). Also the residuals indicate a good representation of data (Figure B.8.2.1-11) and the apparent Kd value over time is very well estimated by the model parameters and the corresponding fit (Figure B.8.2.1-12). Clearly, the kinetic sorption model is a better representation of the measured data than the equilibrium model (c.f. Figure B.8.2.1-09). Additionally, the parameter estimates are derived with very low RSE values well below the proposed threshold of 0.4, *f_ne* is <10 and *k_des* < 0.5 (c.f.Table B.8.2.1-22). The difference to the *Kom_eq* calculated from data at DAT0 accounts for only 9.5% and is thus also within the range of acceptable deviation (Beulke and van Beinum, 2012).

Figure B.8.2.1-11 Residuals for total mass (top) and liquid phase concentration (bottom) in soil Hanscheider Hof and starting value combination version 3

Figure B.8.2.1-12 Measured and fitted apparent Kd value (top) and distribution of mass between equilibrium and non-equilibrium sorption domain (bottom) in soil Hanscheider Hof and for starting value combination version 3

Soil Hoefchen

The equilibrium model fit assuming no kinetic sorption to data for the soil Hoefchen soil is depicted in Figure B.8.2.1-13. Both the total mass and the liquid phase concentration are not very well represented by the model fit. An evaluation of the kinetic sorption magnitude is therefore warranted.

Figure B.8.2.1-13 Equilibrium model fit to Hoefchen soil data.
Total mass depicted at top and liquid phase concentration at bottom.

Table B.8.2.1-23 Parameter optimization for soil Hoefchen, using 4 different starting sets for f_ne and k_des, Chi2-error %and sum of RSE (single rel. standard error RSE in brackets); most appropriate parameter set given in bold

Version	M_ini [µg]	k_des [1/d]	f_ne [-]	DT50_eq [d]	Kom_eq [L/kg]	Chi^2-err [%]	Sum of RSE
1	47.7 (0.0071)	0.0332 (0.1008)	0.3866 (0.0659)	45.7 (0.0175)	46.2 (0.0428)	3.33	0.2340
2	47.7 (0.0071)	0.0332 (0.1012)	0.3867 (0.0661)	45.7 (0.0174)	46.2 (0.0427)	3.33	0.2344
3	**47.7 (0.0071)**	**0.0333 (0.0995)**	**0.3875 (0.00654)**	**45.6 (0.0173)**	**46.1 (0.0419)**	**3.32**	**0.2311**
4	47.7 (0.0070)	0.0332 (0.1008)	0.3868 (0.0662)	45.7 (0.0175)	46.2 (0.0430)	3.33	0.2344

The optimization results for the four starting value combinations of *k_des* and *f_ne* are given in Table B.8.2.1-23. There are only very minor differences between the four estimations and thus a robust parameter set for the kinetic sorption magnitude in the Hoefchen soil can be derived. By means of the Chi2-error percentage and the sum of RSE values the parameter set from version 3 appears as the most appropriate one and will be discussed in more details in the following.

The model fit described by parameter starting value combination 3 is shown in detail in Figure B.8.2.1-14 -Figure B.8.2.1-16. Total mass dissipation and liquid phase concentration are represented very well by the model fit (B.8.2.1-14). Also the residuals indicate a good representation of data (Figure B.8.2.1-15) and the apparent Kd value over time is very well estimated by the model parameters and the corresponding fit (Figure B.8.2.1-16). Clearly, the kinetic sorption model is a better representation of the measured data than the equilibrium model (c.f. Figure B.8.2.1-13). Additionally, the parameter estimates are derived with very low RSE values well below the proposed threshold of 0.4, *f_ne* is <10 and *k_des* < 0.5 (c.f. Table B.8.2.1-23). The difference to the *Kom_eq* calculated from data at DAT0 accounts for only 3.3% and is thus also within the range of acceptable deviation (Beulke and van Beinum, 2012).

Figure B.8.2.1-15 Residuals for total mass (top) and liquid phase concentration (bottom) in soil Hoefchen and starting value combination version 3

Figure B.8.2.1-16 Measured and fitted apparent Kd value (top) and distribution of mass between equilibrium and non-equilibrium sorption domain (bottom) in soil Hoefchen and for starting value combination version 3

Remarks

The study showed that the four data sets obtained for time dependent sorption did meet the quality criteria set in the draft guidance for time dependent sorption (Beulke and van Beinum, 2012). Additionally fitting was done with four different sets of initial parameters. This only resulted in slightly different optimized model results than the initial fitting that was described in study IIA, 7.4.1/04. The values obtained in this study are used for higher tier PECgw calculations. The obtained parameters are reliable and acceptable and can be used for higher tier ground water calculations.

Metabolite 6-CNA

guideline	:	U. S. EPA-FIFRA, 40 CFR, Section 158.290, Subdivision N, Guideline 163-1 EU Commission Directive 95/3 6/EC, Annex I, Section 7.1.2 (14 July 1995) Canada PMRA DACO Number 8.2.4.2, 1987	$K_F$oc	:	70-258
test substance	:	[pyridyl -2,6-^{14}C] 6-chloronicotinic acid	1/n	:	0.894-1.01
purity	:	radiochemical purity 99%	acceptability	:	**acceptable**

Summary

The soil adsorption/desorption of 6-chloronicotinic acid [pyridyl-2,6-^{14}C], was studied in equilibrium experiments using five soils (loamy sand I, loamy sand II, silt loam, clay, and clay loam) as well as in an aquatic pond sediment. The study was conducted at 20±1°C in the dark at five different concentrations (0.035, 0.070, 0.349, 1.170 and 2.319 ppm) in a 0.01 M $CaCl_2$ solution (equivalent to 0.174, 0.349, 1.745, 5.847, and 11.586 ppm in the soil, respectively). The preliminary range-finding study conducted using loamy sand II, silt loam and pond sediment, showed that both adsorption equilibrium and desorption equilibrium were reached at 16 hours. Therefore, the adsorption cycle and each desorption cycle were carried out for 24 hours each in the definitive study. No adsorption of 6-chloronicotinic acid to glass was observed.

Total accountability for all the soils averaged 99% and ranged from 94% to 110% of the applied dose activity with the exception of 0.07 ppm clay (87%). The average % of applied 6-chloronicotinic acid remaining in the supernatants of each phase was as follows:

The Freundlich adsorption (K_f) and desorption (K_{des}) constants as well as adsorption K_{oc} are summarised in Table B.8.2.1-23.

The Freundlich adsorption (K_f) constants ranged from 0.569 for silt loam to 2.121 for pond sediment, averaging 0.981. Adsorption Koc values ranged from 70 for loamy sand II and clay to 258 for loamy sand I. Similar K_f and K_{desl} values for all of the soils and pond sediment shows the reversible equilibration between adsorption and first desorption phases.

Table B.8.2.1-23 ~~Average % of applied 6-CNA remaining in the supernatants~~ Adsorption and desorption constants of 6-CNA in six soils

Soil type	OC [%]	pH	Adsorption			Desorption

Pond sediment (Sandy Loam) **	*4.32*	*5.6*	*0.867*	*2.121*	*85*	*3.144*	*1.243*	*2.551*
Average soils			**0.949**	**0.780**	**88**			

*: not considered for calculation of mean since the OC was regarded as too low
**: pond sediment not considered for calculation of mean in soils

Remarks

The results of the adsorption desorption study with 6-CNA is acceptable and reliable. The sorption did not show pH-dependency. The pH range of the used soils is within the typical range of agricultural soils and there is no indication of a pH dependence of the sorption. This is not unexpected as the pKa of 6-CNA (3.28) indicate full ionsiation above pH 5 and hence no influence of the pH of the soil would be expected. The endpoints will be used for risk assessment. In the calculation of the mean the values of loamy sand I and pond sediment are not taken into account.

Metabolite DFA

STUDY IIA, 7.4.2/02

Characteristics

reference	:	Menke, U., Unold, M., 2011	soils	:	five soils; silt loam, loam, clay loam, sandy loam, silty clay loam
year of execution	:	2010	concentrations	:	1.0, 0.3, 0.1, 0.03, and 0.01 mg/L
GLP statement	:	yes	temperature	:	20±1°C
guideline	:	Incl. OECD 106 (2000)	$K_F$oc	:	70-258
test substance	:	[1-^{14}C] BYI 02960-DFA	1/n	:	0.894-1.01
purity	:	radiochemical and chemical purity: >98% / 99.5%	acceptability	:	**acceptable**

Summary

The adsorption/desorption behavior of BYI 02960-DFA was studied in batch equilibrium experiments in five soils originating from Germany and the USA.

The adsorption phase of the study was carried out using pre-equilibrated air-dried soils in 0.01 M aqueous $CaCl_2$ solution with a soil to solution of 1:1.25 for soil Dollendorf II and soil to solution ratios of

1:1 for soils Hoefchen am Hohenseh 4a, Hanscheiderhof, Sanger and Springfield. BYI 02960-DFA was applied at concentrations of nominal 1.0, 0.3, 0.1, 0.03, and 0.01 mg/L supernatant.

Desorption experiments were performed by supplying pre-adsorbed soil samples with fresh 0.01 M aqueous $CaCl_2$ solution. One desorption cycle was performed for all concentrations and three desorption cycles were performed for the highest concentration only.

Adsorption and desorption took place in the dark at 20 ± 1 °C for 24 hours with triplicate samples, respectively. The aqueous supernatant after adsorption and desorption was separated by centrifugation, and the BYI 02960-DFA residue in the supernatant was analyzed by liquid scintillation counting (LSC). The adsorption and desorption parameters were calculated using the Freundlich equation.

The test item was stable throughout the study. The mass balance of the parent compound determined for all soils at the highest concentration was >90%. In the definitive adsorption test 16.9 - 25.3%, 16.6 - 34.9%, 22.3 - 26.6%, 2.6 - 10.7% and 2.4 - 5.7% of the applied test item were adsorbed to soils Hoefchen am Hohenseh 4a, Hanscheiderhof, Dollendorf II, Sanger and Springfield, respectively.

The calculated adsorption constant $K_{F(ads)}$ of the Freundlich isotherms for the five test soils ranged from 0.028 - 0.368 mL/g, the $K_{oc(ads)}$) from 1.7 – 9.5 mL/g. The Freundlich exponent 1/n was in the range of 0.6902 to 0.9579, indicating that the concentration of the test item affected the adsorption behavior in the examined concentration range.

The $K_{oc(des)}$ values were 12.7 - 57.1 times higher than the $K_{oc(ads)}$ values, indicating a strong binding of the test item to the soil. Soils Dollendorf II and Springfield did not show an acceptable linearity of the Freundlich desorption isotherms and therefore desorption constants could not be calculated. For the highest concentration of each soil, a second and a third desorption step were performed. In these steps, the desorbed amounts of BYI 02960-DFA range from 13.4 to 45.2% of the adsorbed amount, indicating that the binding is partly reversible. The following table summarizes the key data of this study. BYI 02960-DFA can be classified as very mobile for adsorption and low mobile for desorption.

Table B.8.2.1-24 Key data and results of study

Soil origin	**Hoefchen am Hohenseh 4a, Germany**	**Hanscheider Hof, Germany**	**Dollendorf II, Germany**	**Sanger, USA**	**Springfield, USA**
Soil type (USDA)	Silt Loam	Loam	Clay loam	Sandy Loam	Silty Clay loam
pH (aqueous $CaCl_2$ solution)	6.5	5.8	7.4	6.0	6.5

$K_{F(ads)}$ [mL/g]	0.228	0.226	0.368	0.033	0.028
1/n	0.9053	0.8013	0.9579	0.6902	0.8194
$K_{oc(ads)}$ [mL/g]	9.5	7.8	8.2	6.7	1.7
$K_{oc(des)}$ [mL/g]	121.3	155.5	*	380.7 **	*
Arithmetic mean $K_{oc(ads)}$: 6.8 mL/g; $K_{oc(des)}$: 219.1 mL/g					

* The correlation coefficient determined for the Freundlich desorption isotherms was not significant
** For soil Sanger (SA) the highest concentration (1 mg/L) was not included in the calculation of the Freundlich desorption isotherm due to a negative supernatant concentration calculated for one replicate

Material and Methods

Materials

1. Test Item: BYI 02960-DFA Code BCS-AB60481; CAS no. 2218-52-2 [sodium salt]; 381-73-7 [free acid]; [1-14C] BYI 02960-difluoro-acetic acid: sample ID KATH 6450; Specific activity: 76.68 µCi/mg (2.84 MBq/mg); Radiochemical and chemical purity: >98% / 99.5% (at beginning of study); The test item was identified by LC-MS, LC-MS/MS and NMR)

The ^{14}C-test item was dissolved in TKA-water (approx. 1.6 mg/mL) after arrival at the testing facility and stored in a freezer in the dark. Radiopurity of the labeled test item was checked by TLC analysis.

2. Soils: The adsorption/desorption behavior of DFA was studied in batch equilibrium experiments in five soils originating from Germany and the USA: Hoefchen am Hohenseh 4a, silt loam, pH 6.5, 2.4% organic carbon; Hanscheiderhof, loam, pH 5.8, 2.9% organic carbon; Dollendorf II, clay loam, pH 7.4, 4.5% organic carbon; Sanger, sandy loam, pH 6.0, 0.5% organic carbon; Springfield, silty clay loam, pH 6.5, 1.7% organic carbon (pH values derived from aqueous CaCl2 suspension). The pH values of the soil batches were measured in 0.01 M aqueous $CaCl_2$. The soils were air-dried and homogenized by sieving (≤ 2 mm) and stored in a climate chamber at 5 °C. The detailed parameters of soils are shown in Table B.8.2.1-25.

Methods

1. Experimental conditions: In the definitive test, 16 g of soil Dollendorf II and 20 g of soils Hoefchen am Hohenseh 4a, Hanscheiderhof, Sanger and Springfield were weighed into the centrifuge tubes and aqueous 0.01 M $CaCl_2$ solution was added to a solution volume of 18 mL (corrected for soil humidity). After pre-equilibration by shaking for about three days, 2 mL of the respective application solution were added. The adsorption/desorption measurements were performed over a range of five BYI 02960-DFA concentrations (0.01 mg/L to 1.0 mg/L), covering two orders of magnitude. The samples were incubated at constant temperature in the dark and continuously agitated using an overhead shaker. After a certain time the suspensions were centrifuged and the supernatants were analyzed by LSC. Additionally, the pH values of the supernatants were determined.

For the desorption experiments the supernatants were removed, measured, and replaced by an equivalent volume of aqueous 0.01 M $CaCl_2$ solution. After agitation (for e.g. 24 h in the definitive test) and centrifugation, the supernatant was decanted, measured, and analyzed by LSC. One desorption step was performed for the samples of all five concentration levels whereas three desorption steps were performed for the samples of the highest concentration level.

Mass balances were calculated for the one sample of each concentration level. For this purpose, the remaining soil was freeze-dried, grounded, combusted, and analyzed by LSC. Due to the stability of the test item, the partition of the test item was determined based on the amount of RA measured in the supernatant by LSC. The adsorption and desorption experiments were performed in triplicate.

2. Application procedures: The total amount of [1-^{14}C] BYI 02960-DFA delivered (6.5 mg) was dissolved in 4 mL TKA-water resulting in a solution containing approximately 1.6 mg test item/mL. In the definitive test, the soil to solution ratio for soils Hoefchen am Hohenseh 4a, Hanscheiderhof, Sanger and Springfield was 20 g soil to 20 mL of 0.01 M aqueous $CaCl_2$ solution. For soil Dollendorf II, the soil to solution ratio was 16 g soil to 20 mL 0.01 M aqueous $CaCl_2$ solution. The nominal concentrations of radiolabeled BYI 02960-DFA were 0.01, 0.03, 0.1, 0.3, and 1.0 mg/L. Using pipette aliquots of 2 mL, the radiolabeled BYI 02960-DFA application solutions were added to the pre-equilibrated suspensions consisting of 16 or 20 g soil and 18 mL 0.01 M aqueous $CaCl_2$ solution.

[A]) According to USDA classification
[B]) Calculated: Organic matter = organic carbon * 1.724
[C]) Determination method: Combustion

3. Analytical procedures: The stability of the test item was determined by TLC of the control samples and of supernatants and extracts of the soil samples (highest concentration) in the pre-tests. The test item was considered to be stable (parental mass balance >90). The limit of quantification (LOQ) was

set to three times the background radioactivity, i.e. about 0.96 Bq (0.33 ng). The lowest amount measured was about 5.5 Bq, i.e. about 5.7 times higher than the LOQ.

In the definitive test supernatants were analyzed by liquid scintillation counting (LSC). After the desorption step, for the calculation of the mass balance, the remaining soil was freeze-dried and combusted. The trapped $^{14}CO_2$ after combustion was measured by LSC. Due to the stability of the test item, the partition of the test item was determined based on the amount of RA measured in the supernatant by LSC.

Results and Discussion

Mass Balance

The overall material balance for all soils was in the range of 95.1-100.3% (mean: 97.2%) of the applied radioactivity. The complete material balances found at all sampling intervals demonstrated that no significant RA dissipated from the test vessels or was lost during processing.

Table B.8.2.1-26 Recovery of Total Radioactivity of BYI 02960 after Adsorption and Desorption Steps (Expressed as percentage of applied radioactivity)

Description Soil ID Conc. ID	Soil 1 HF (% of AR)	Soil 2 HN (% of AR)	Soil 3 DD (% of AR)	Soil 4 SA (% of AR)	Soil 5 SF (% of AR)

Stability and Recovery of Test Item

The stability of DFA in the test system used was confirmed by performing HPLC analyses prior to the definitive test. Recoveries of radioactivity in the 0.01 M $CaCl_2$ solutions of control samples without soil range from 99.8 to 100.7% of applied radioactivity (0 – 96 h). The test item was stable in control samples without soil.

Findings

In the definitive adsorption test 16.9 - 25.3%, 16.6 - 34.9%, 22.3 - 26.6%, 2.6 - 10.7% and 2.4 - 5.7% of the applied test item were adsorbed to soils Hoefchen am Hohenseh 4a, Hanscheiderhof, Dollendorf II, Sanger and Springfield, respectively. The adsorption behavior of BYI 02960-DFA in the concentration range of two orders of magnitude (i.e. from 0.01 - 1.0 mg/L) was accurately described for all soils with the Freundlich equation. The correlation coefficient of the individual isotherms was in the range of 0.9699 - 0.9984. The calculated adsorption constants $K_{F(ads)}$ of the Freundlich isotherms for the five test soils ranged from 0.028 - 0.368 mL/g. The Freundlich exponents 1/n were in the range of 0.6902 -

0.9579, indicating that the concentration of the test item affected the adsorption behavior in the examined concentration range.

* Expressed as a percentage of the initially adsorbed material, one desorption step for all concentrations
** The subtraction of the remaining radioactivity in solution from the measured concentrations resulted in negative liquid concentrations for some samples. Therefore the mean concentration was not presented and the percentage of desorbed test item was not calculated for this concentration level

The adsorption coefficients $K_{F(ads)}$ were correlated with the organic carbon content of the soil, in order to get a comparability of the adsorption behavior in different soils. For DFA the calculated $K_{oc(ads)}$ values varied between 1.7 and 9.5 mL/g (mean: 6.8 mL/g).

One desorption step was performed for all concentrations. For soils Hoefchen am Hohenseh 4a and Hanscheiderhof this first desorption step resulted in highly significant correlation coefficients for the Freundlich isotherm with values of 0.9788 and 0.9884. When omitting the highest concentration, the first desorption step of soil Sanger had a significant correlation coefficient as well (0.9801). At the end of the first desorption phase, 19.8 - 26.3%, 16.2 - 21.2% and 38.5 - 44.2% of the initially adsorbed amount was desorbed in soils Hoefchen am Hohenseh 4a, Hanscheiderhof and Sanger, respectively. The other soils (Dollendorf II and Springfield) did not show an acceptable linearity of the Freundlich desorption isotherms and therefore, desorption constants could not be calculated.

The calculated desorption constants $K_{F(des)}$ of the Freundlich isotherms for the three evaluated test soils ranged from 1.903 - 4.509 mL/g. The respective mean $K_{oc(des)}$ values was 219.1 mL/g). The $K_{oc(des)}$ values were 12.7 to 57.1 times higher than the $K_{oc(ads)}$ values, indicating a strong binding of the test item to the soil. For the summary of results see Table B.8.2.1-29.

Table B.8.2.1-29 Adsorption and desorption constants of BYI 02960-DFA in five soils

Soil	Adsorption				Desorption			
	K_F (mL/g)	1/n	R^2	Koc (mL/g)	K_F (mL/g)	1/n	R^2	Koc (mL/g]

HF	0.228	0.9053	0.9945	9.5	2.911	0.975	0.9788	121.3
HN	0.226	0.8013	0.9903	7.8	4.509	1.013	0.9884	155.5
DD	0.368	0.9579	0.9984	8.2	*	*	*	*
SA	0.033	0.6902	0.9769	6.7	1.903**	1.052**	0.9801**	380.7**
SF	0.028	0.8194	0.9699	1.7	*	*	*	*
Arithmetic mean	**0.177**	**0.8348**	**0.9860**	**6.8**	**3.1**	**1.0**	**1.0**	**219.1**

* The correlation coefficient determined for the Freundlich desorption isotherms was not significant
** For soil Sanger (SA) the highest concentration (1 mg/L) was not included in the calculation of the Freundlich desorption isotherm due to a negative supernatant concentration calculated for one replicate

Conclusions

DFA can be classified as very mobile for adsorption and low mobile for desorption.

Remarks

The results of the adsorption desorption study with DFA is acceptable and reliable. The sorption did not show pH-dependency. The pH range of the used soils is within the typical range of agricultural soils and there is no indication of a pH dependence of the sorption. This is not unexpected as the pKa of DFA (1.57) indicate full ionsiation above pH 5 and hence no influence of the pH of the soil would be expected. The endpoints will be used for risk assessment.

B.8.2.2 Column leaching studies, leaching of aged residues and field leaching studies (Annex IIA 7.1.3.1, 7.1.3.2, 7.1.3.3; Annex IIIA 9.1.2.1, 9.1.2.2)

Reliable adsorption values were determined by batch equilibrium experiments according to OECD guideline 106. Therefore, no column leaching studies have to be performed with BYI 02960 and soil metabolites. A colomn leaching study was submitted and included for completeness.

Summary

In the EU and NAFTA this requirement is covered by the adsorption/desorption studies with the parent compound as presented in chapter B.8.2.1. However, a soil column leaching study for the active substance was performed in order to fulfill a requirement of Brazilian registration authorities. A short summary of that study is given as follows.

The leaching behaviour of [pyridine-2,6-^{14}C]-BYI 02960 was studied in four Brazilian soils under laboratory conditions according to OECD Guideline Method 312 (2004). The four soil types were

Argissolo (clay), Latossolo vermelho (clay), Neossolo (loamy sand/sandy loam) and Gleissolo humico (loam). Duplicate glass columns per soil type were filled with the respective soil to a height of 30 cm. After conditioning with 0.01 M $CaCl_2$ solution [PYR-^{14}C]-BYI 02960 was applied to the top of the columns at a dosage approximating a maximum application rate of 1500 g a.i./ha. Monuron was used as a reference substance and was applied at a rate of 5 kg a.i./ha. After the application of test and reference substance each column was irrigated with 200 mm of artificial rain over a 48-hrs period, and the respective leachate samples were collected. After percolation, the soil columns were divided into six layers of ca. 5 cm each, and the soil samples were extracted with acetonitrile:water (80:20 v/v). Layers containing more than 10% of applied radioactivity (AR) were sequentially extracted until the last extract represented less than 10% of AR. Extracted radioactivity was analyzed by high-performance liquid chromatography (HPLC) with radiometric detection. The results of the HPLC analysis did not show degradation of the parent compound during the timescale of the study.

The average mass balance ranged from 96.6 - 106.3% in the four tested soils. Extractable radioactivity ranged for all soils from 73.75 - 95.26%, and non-extractable radioactivity ranged from 3.64 - 25.22%.
No radioactivity (<LOQ) was detected in the leachate of Argissolo and Gleissolo soils. Thus the AR was completely retained in Argissolo and Gleissolo soils, however, percolated to the leachate in Latossolo and Neossolo soils after application of the artificial rain. In the leachates of Latossolo and Neossolo mean 14.93 and 23.50% of AR were detected, respectively. Analysis of the leachates showed that there was detectable Monuron in the leachate of Argissolo soil (one replicate), Latossolo and Neossolo soils.

The maximum (mean) depth penetration of the radioactivity in the soil profiles was < 10 cm for Argissolo soil, > 30 cm for Latossolo, > 30 cm for Neossolo, and ≤ 7.5 cm for Gleissolo soil, whereas the leaching depth of Monuron was ≤ 27.5, > 30, > 30 and < 7.5 cm in the respectively listed soils.

In order to compare leaching data from different experiments, a relative mobility factor (RMF) to a reference chemical such as Monuron was used. Monuron is known to be moderately mobile in the field. Knowing the RMF values of crop protecting compounds allows their classification into mobility classes. The relative mobility factor (RMF) for BYI 02960 was 0.45 for Argissolo soil, 1.0 for Latossolo, 1.0 for Neossolo soil and 1.0 for Gleissolo soil. Based on these values, BYI 02960 can be classified as little mobile in Argissolo and moderately mobile in Latossolo, Neossolo and Gleissolo soils.

B.8.2.3 Lysimeter studies (Annex IIA 7.4.7 to 7.4.8; Annex IIIA 9.3.2 to 9.3.3)

Reliable adsorption values for parent and metabolites were determined by batch equilibrium experiments according to OECD guideline 106 (2000). The potential of leaching to groundwater for the parent and metabolites can be predicted from the available data. Therefore, no lysimeter study is considered necessary.

B.8.2.4 Summary adsorption, desorption and mobility in soil

Batch adsorption studies BYI 02960

Batch adsorption studies were performed for BYI 02960 and two major soil metabolites. The equilibrium sorption BYI 02960 was studied in two batch equilibrium studies in the laboratory at 20°C with six different soils and one time dependent sorption experiment. The data of the batch experiments were evaluated to derive Freudlich isotherms. The resulting arithmetic mean values for 1/n, Kf (ads) and Koc were 0.866, 2.263 (L/kg) and 98.4 (L/kg (Table B.8.2.4-01). The desorption Kf (des) and the normalized K_{OC}(des) values were significantly higher (i.e. approx. 2 times) than those obtained for the adsorption phase, indicating that the test item once adsorbed to soil is not readily desorbed. BYI 02960 can be classified as intermediate mobile for adsorption and low mobile for desorption.

Table B.8.2.4-01 Adsorption measurements for BYI 02960

Soil	Soil Type (USDA)	pH ($CaCl_2$) [-]	K_f [mL g^{-1}]	1/n [-]	$K_{f,oc}$ [mL g^{-1}]
Laacherhof AXXa	Sandy loam	6.2	2.077	0.8445	98.9
Hoefchen am Hohenseh 4a	Loam	6.6	2.213	0.8682	92.2
Hanscheiderhof	Loam	5.3	2.354	0.8643	107.0
Dollendorf II	Loam	7.2	3.822	0.8648	74.9
Sanger	Sandy Loam	6.8	0.597	0.9021	85.2
Springfield	Silt loam	6.5	1.554	0.8505	132.2
Arithmetic mean		**-**	**-**	**0.8657**	**98.4**

* $K_{oc,EQ}$ restults of the TDS included in the average caluclation

Time dependent sorption study BYI 02960

Time dependent sorption (TDS) of BYI 02960 was studied in four soils a maximum period of 120 days under aerobic conditions in the dark at ca. 20°C and 55% WHCmax. At the beginning of the study the distribution coefficient values RTDS were 1.46, 1.91, 3.35 and 4.66 mL/g for soils AX, HF, HN and DD, respectively. Based on results from the ageing time of 120 days, the RTDS values increased by a factor of 4.4, 2.9, 3.2 and 2.6 (mean of all four soils = 3.3).

A more detailed evaluation showed that the before-mentioned experimental data can be well described by a kinetic-sorption model, with excellent fits and reliable parameter estimates. Such time-dependent sorption data received for BYI 02960 constitute the prerequisite to adequately address the obvious TDS process in higher tier regulatory modelling, e.g. related to a potential groundwater contamination. For BYI 02960 a fitted mean $K_{oc,eq}$ of 80.2 L/kg ($K_{om,eq}$ of 46.5 L/kg) and the Freundlich exponent 1/n of 0.8605 can be used in higher tier simulation runs (arithmetic mean of the 1/n of the four soils used for the batch sorption and identiacal as the soils used for TDS).

The RMS intendedat first to use both the batch adsorption and time dependent sorption (TDS) K_{oc} and $K_{oc,eq}$ to obtain a arithmetic mean K_{oc}. The RMS did this on basis of the EFSA opinion on the science behind the guidance for scenario selection and scenario parameterisation for predicting environmental concentrations of plant protection products in soil (ESFA Journal 2012;10(2)2562). It is advised to use in each tier, all available relevant scientific information. The RMS was aware that in the guidance on

how aged sorption studies for pesticides should be conducted, analysed and used in regulatory assessments (Beulke S. and Van Beimum W. 2012, DEFRA projects PS2235 and PS2244) a different opinion is presented, i.e. not to combine the TDS and batch adsorption/desorption data. This UK guidance on TDS is not yet adopted in Europe and also the opinion is not adopted. After a discussion with the applicant and external experts, the RMS decided to not include the TDS $K_{oc,EQ}$ data in the first tier data set for the K_{oc}. The first tier arithmetic mean K_{oc} value is 98.4 L/kg, this is the average of the six batch adsorption values.

Batch adsorption studies for metabolites

The equilibrium sorption of 6-chloronicotinic acid (6-CNA) was studied in experiments using five soils and an aquatic pond sediment. The arithmetic mean 1/n value for soil was 0.9495, adsorption Koc values in soils ranged from 70 to 258, averaging 88.0 (L/kg). Similar Kf and Kdes values for all soils indicated a reversible equilibration between adsorption and first desorption phases. 6-CNA can be classified as medium to high mobile for adsorption and desorption.

The equilibrium sorption of difluoroacetic acid (DFA) was studied in experiments using five soils. The arithmetic mean 1/n value for soil was 0.8348, adsorption Koc values ranged from 1.7 to 9.5, averaging 6.8 (L/kg). The Koc(des) values were 12.7 to 57.1 times higher than the Koc(ads) values, indicating a strong binding of the test item to the soil. BYI 02960-DFA can be classified as very mobile for adsorption and low mobile for desorption.

The results of the batch adsorption analyses performed for the metabolites are reported below (see Table B.8.2.4-02 and Table B.8.2.4-03).

Table B.8.2.4-02 Adsorption measurements for 6-chloronicotinic acid

B.8.3 Predicted environmental concentrations in soil (PECs) (Annex IIIA, 9.1.3)

Calculations were based on a simple first tier approach (Excel sheet) assuming even distribution of the compound in upper 0-5 cm soil layer. A standard soil density of 1.5 g/cm^3 was assumed. Crop interception data which correspond to the intended growth stages were taken from the FOCUS groundwater guidance paper (FOCUS 2010).

Crop interception will reduce the amount of a compound reaching the soil and therefore this has been taken into account depending on the growth stage at application. The interception rates follow the recommendations of the FOCUS groundwater guidance paper (FOCUS 2010) provided in Table B.8.3-01. As hop and lettuce have not been defined in the FOCUS groundwater guidance paper, vines and cabbage were chosen as surrogate crops. As there is currently no guidance on calculation of PEC_{soil} for greenhouse crops no specific calculation was performed and it is assumed that the glasshouse use is covered by the outdoor use on lettuce.

Study design

Methods and Materials: The predicted environmental concentrations in soil (PEC_{soil}) of BYI 02960 were estimated using a simple first tier approach. Detailed application data used for simulation of PEC_{soil} are compiled in Table B.8.3-01. PEC soil were not calculated for the glasshouse uses of the product.

Substance Specific Parameters: PEC_{soil} calculations were based on the DT_{50} of 0.02 days for the fast and 462 days for the slowly degrading compartments (DFOP, worst case of field dissipation studies, k_1=34.66 and k_2=0.0015 and g =0.27).

Table B.8.3-01 Application pattern used for PEC_{soil} calculations of BYI 02960

Individual Crop	FOCUS Crop Used for Interception	Application				Amount Reaching the Soil per Season application [g a.s. /ha]
		Rate per Season [g a.s. /ha]	Interval [days]	Plant Interception [%]	BBCH Stage

Lettuce 1 (F), GAP – identical with simulation [1)]	Cabbage	1 x 125	-	25	12-49	1 x 94
Lettuce 2 (F), GAP – identical with simulation [2)]	Cabbage	1 x 125	-	70	41-49	1 x 37.5

[1)] Max 1 application per 24 months (biennual)
[2)] Max 1 application per 12 months (annual)
F = field use

To account for potential accumulation of BYI 02960 in soil (worst-case non-normalised DFOP DT_{90} > 365 days), long-term soil concentrations were calculated.

Findings: The PEC_{soil} and the time weighted average values (TWA_{soil}) of BYI 02960 are summarised in Table B.8.3-02 for hops and in for lettuce Table B.8.3-03.

Table B.8.3-02 PEC_{soil} (actual) and TWA of BYI 02960 in hops in the upper 5 cm, DFOP decay

[2)] Max 1 application per 12 months (annual)

Accumulation in soil

The potential accumulation of BYI 02960 in soil was calculated considering the following approaches:

- Maximum soil residue in first year: maximum soil residue calculated for one season.
- Long-term plateau concentration C_{min}: maximum of the lower saw tooth curve, which can be considered as background concentration after multiple year use.
- Long-term maximum concentration C_{max}: maximum of the upper saw tooth curve after multiple year use.
- Background C_{min} + maximum of one year in 5 cm depth: to the long-term background concentration C_{min} in a certain depth (e.g. 5, 10 or 20 cm), the maximum residue of one year (distributed in 5 cm) will be added, to take into account a conservative shallow distribution just after an annual application.

Table B.8.3-04 Long-term soil concentrations of BYI 02960 following multi-year use

	Residues distributed over … [cm]	Seasonal $PEC_{s, max}$, max. soil residue in 1st year [mg/kg]	Long-term plateau / background conc. C_{min} [mg/kg]	Long-term maximum conc. C_{max} [mg/kg]	Background C_{min} + max. of 1 year in 5 cm [mg/kg]
Hops 1 x 150 g/ha	**5**	0.080	0.080	**0.160**	-
	10	0.040	0.040	0.080	0.120
	20	0.020	0.020	0.040	0.100
Lettuce 1 [1)] 1 x 125 g/ha	5	0.125	0.046	0.171	-
	10	0.063	0.023	0.085	0.148
	20	0.031	0.011	0.043	**0.136**
Lettuce 2 [2)] 1 x 125 g/ha	5	0.050	0.050	0.100	-
	10	0.025	0.025	0.050	0.075
	20	0.013	0.013	0.025	**0.063**

[1)] Max 1 application per 24 months (biennial)
[2)] Max 1 application per 12 months (annual)
In bold: Generally, for long-term assessments the substance distribution in soil for annual crops with tillage should be assumed over a depth of 20 cm (lettuce) and for perennial crops without tillage over a depth of 5 – 10 cm (e.g. hops).

Remarks by RMS

The RMS recalculated all the values with the DFOP worst case input of the UK field study. Using DFOP kinetics identical results were obtained by the RMS. Therefore the RMS accepts the PEC_{soil} calculations from the applicant. The long term soil concentrations for hop were assessed applying it every year. This differs from the applied biennial usage in hop in the GAP however the assessed value covers the biennial usage. The indoor use was not assessed since this soil is not considered a natural habitat for soil organisms. Soils are often sterilized before and during use in glasshouses. Therefore, PECsoil for the use in glasshouse is not included.

STUDY IIIA, 9.5/01 and STUDY IIIA, 9.5/02 and STUDY 9.5/03

Predicted environmental concentrations in soil were calculated for the major soil metabolites DFA and 6-CNA. These metabolites are not automatically "relevant" with regard to their environmental, biological, eco-toxicological or toxicological properties.

Reference/notifier	:	Sur R., Ellerich C.; 2012 and 2013 Scherr F., Ellertich C.; 2014	GLP statement	:	No
type of study	:	PECs calculation	guideline	:	Soil Persistence Models and EU registration: Report of the FOCUS Soil Modelling Work Group, 1996. EC Document Reference 7617VI/96
year of execution	:	2012 and 2013	acceptability	:	**acceptable**
test substance	:	BYI 02960-DFA and BYI 02960-CNA			

Methods and Materials: PEC_{soil} for the metabolites were calculated using the approach, scenarios and application rates described for the calculations for the parent compound in study IIIA, 9.4/01. Compound specific parameters are summarised in Table B.8.3-05.

Table B.8.3-05 Input parameters for PEC_{soil} for metabolites of BYI 02960

Compound	Max. DT_{50} [days]	Max. occurrence in soil [%]	Molar mass [g/mol]	Molar mass correction factor
Difluoroacetic acid	73.6	33.9	96.03	0.333
6-Chloronicotinic acid	36.6	17.1	157.56	0.546

Findings: The maximum PEC_{soil} values of metabolites of BYI 02960 are summarised in Table B.8.3-06.

Table B.8.3-06 Hops and Lettuce: PEC_{soil} (max) of BYI 02960 metabolites

Crop	DFA $PEC_{soil, max}$ [mg/kg]	6-CNA $PEC_{soil, max}$ [mg/kg]
Hops 1 x 150 g/ha of parent	0.009	0.007
Lettuce 1, 1 x 125 g/ha of parent [1)]	0.014	0.012
Lettuce 2, 1 x 125 g/ha of parent [2)]	0.006	0.005

[1)] Max 1 application per 24 months (biennial)
[2)] Max 1 application per 12 months (annual)

PEC_s accumulation of the metabolites

The long term maximal concentration of the active substance are reported in Table B.8.3-04. These concentrations are for hops 0.160 mg/kg over 5 cm, 0.043 mg/kg for lettuce (biennial application) and 0.025 mg/kg for lettuce (annual application) over 20 cm. Using these concentrations and taking the maximal percentage observed and molecular weight of the metabolites in to account (Table B.8.3-05) results in a seasonal $PEC_{s,max}$. When using these togehter with the maximal DT_{50} values of both metabolites the $PEC_{plateau}$ of the metaolbites and long term $PEC_{s,max}$ can be calculated. Table B.8.3-07 and -08 give the results for the metalobites DFA and 6-CNA.

Table B.8.3-07 Long-term soil concentrations of DFA following multi-year use

	Residues distributed over … [cm]	Seasonal $PEC_{s, max}$, max. soil residue in 1st year [mg/kg]	Long-term plateau / background conc. C_{min} [mg/kg]	Long-term maximum conc. C_{max} [mg/kg]
Hops 1 x 150 g/ha	**5**	0.018	0.001	0.019
Lettuce 1 [1)] 1 x 125 g/ha	**20**	0.005	<0.001	0.005
Lettuce 2 [2)] 1 x 125 g/ha	**20**	0.003	<0.001	0.003

[1)] Max 1 application per 24 months (biennial); [2)] Max 1 application per 12 months (annual)

Table B.8.3-08 Long-term soil concentrations of 6-CNA following multi-year use

	Residues distributed over … [cm]	Seasonal $PEC_{s, max}$, max. soil residue in 1st year [mg/kg]	Long-term plateau / background conc. C_{min} [mg/kg]	Long-term maximum conc. C_{max} [mg/kg]
Hops 1 x 150 g/ha	**5**	0.015	<0.001	0.015
Lettuce 1 [1)] 1 x 125 g/ha	**20**	0.004	<0.001	0.004
Lettuce 2 [2)] 1 x 125 g/ha	**20**	0.002	<0.001	0.002

[1)] Max 1 application per 24 months (bienniall);[2)] Max 1 application per 12 months (annual)

Remarks by RMS

The RMS agrees with the obtained PECsoil values for the parent and metabolites. The long term soil concentrations for hop were assessed applying it every year. This differs from the biennial usage in hop in the GAP however the assessed value covers the biennial usage.

B.8.4 Fate and behaviour in water (Annex IIA 7.2.1; Annex IIIA 9.2.1/9.2.3)

B.8.4.1 Hydrolysis (Annex IIA 7.2.1.1) OECD number 7.5

STUDY IIA 7.5/01

Characteristics

reference	:	Mislankar, S., Woodard, D., 2011		purity	:	radiochemical purity 99%.
study type	:	hydrolysis		nominal concentration	:	1.0 mg/L
year of execution	:	2009		pH	:	4, 7, 9
GLP statement	:	yes		temperature	:	50°C
guideline	:	JMAFF (2000), EPA 161-1, PMRA DACO Number 8.2.3.2, OECD 111 (2002)		conclusion	:	hydrolytically stable
test substance	:	[furanone-4-^{14}C] BYI 02960		acceptability	:	**acceptable**

Summary

Hydrolysis of radiolabeled [furanone-4-^{14}C] BYI 02960 at 1.0 mg a.i./L was studied in the dark at 50 °C in sterile aqueous buffers at pH 4 [acetate buffer], pH 7 [tris buffer], and pH 9 [borate buffer] for 5 days. Samples were analyzed at 0, 1, 2, 3, 4 and 5 days. The samples were analyzed directly by HPLC without extraction.

The results showed that BYI 02960 is hydrolytically stable at ambient temperature. Most of the applied radioactivity was associated with the parent compound at test termination in the pH 4, 7 and 9 buffer solutions. There were three minor components which accounted for a total of 4.9% of AR, none was more than 2.7% of AR in any of the pH.

A preliminary study was conducted at 50°C to determine if volatiles would be formed. It demonstrated that no volatiles were formed during hydrolysis. This result was further confirmed by the acceptable recoveries observed in the definitive experiments.

Materials amd Methods

Materials

1. Test Item: Code BYI 02960, CAS no. 951659-40-8 (unlabelled substance); Label position = [Furanone-4-^{14}C] BYI 02960 (vial No. C-1116); Specific activity: 30.74 mCi/mMole (3.94 MBq/mg) Radiochemical purity: 99% (at beginning of study); Identity and purity of test item in the application solutions were checked. The radiochemical purity of the dosing solution (test item in85 µL acetonitrile, each) was determined by HPLC and found to be 96%.

2. Test matrix: The test matrices for this study were a 0.01 M sodium acetate/acetic acid solution (pH 4), a 0.01 M tris(hydroxymethyl)aminomethane/HCl solution (pH 7), and a 0.01 M boric acid/NaOH solution (pH 9). The acetate, tris, and borate buffers were used since they are unlikely to affect the rate of hydrolysis at their respective pH.

Methods

1. Experimental conditions: The test system consisted of a 30 mL amber vial containing 10 mL of buffer and capped with a septum lined crimp cap. It was autoclaved for 60 minutes at >93 °C to sterilize the system. Forty-five test systems were prepared consisting of three groups of 15 vials, one group for each pH (4, 7, and 9). This included 6 time points, 2 replicates per interval and 3 extra vials. Each vial was filled with 10 mL of the appropriate buffer and sealed with a crimp cap equipped with a Teflon™-lined septum. The test systems were autoclaved for 60 minutes at >93°C to sterilize the system. Test systems were allowed to cool to room temperature before the addition of the test material.

No volatiles were observed in the preliminary experiment. Therefore, no trapping system was used.
The test systems were maintained in a covered water bath. The temperature was held at 50 ±0.5 °C. The pH and sterility were measured at each sampling interval.

2. Application Procedures: 100-µL Hamilton syringe was used to deliver 85 µL of application solution to each test containing 10 ml of buffer. The septum of the each vial was pierced by the syringe, and the application solution was added. To check the DPM applied to the system, using the same syringe, 85 µl of application solution was first put into two vials containing 10 ml of water. Then all the buffers were treated with 85 µl of application solution. After this another aliquot of 85 µl was put into two vials containing 10 ml of water. Three aliquots were taken from each vial for a total of 12 samples and analyzed by LSC which gave average of 240,371 dpm /mL equivalent to 1 ppm

3. Sampling: The sampling intervals for all three pH values were 0, 1, 2, 3, 4 and 5 days post treatment. Samples were typically analyzed the day of sampling with the maximum storage duration before analysis of less than 24 hrs. The samples were stored under refrigerated conditions before analysis if analysis was not conducted on the sampling date. No storage stability data was generated because samples were analyzed within one day of collection.

4. Analytical procedures: At each interval, two replicate test systems for each pH were removed from the water bath, three 1-mL aliquots were counted on the liquid scintillation counter (LSC) and 1 mL of each sample was directly analyzed by HPLC.

The retention time for [^{14}C] BYI 02960 using the HPLC system was 22.0 minutes. Recovery of radioactivity from the HPLC column ranged from 94.2 - 99.2% with a mean recovery of 97.1%.
The linearity of the detector's response to 14C was confirmed. The limit of quantitation (LOQ) was determined empirically by a series of injections at decreasing concentrations. The lowest concentration that resulted in a peak 2 to 3 times the background level was determined to be the LOQ. The limit of quantitation used in this experiment was 890 dpm. Defining 445 dpm as the limit of detection (LOD) of the HPLC radio detector a minimum of approximately 1.1% or 1.6 ppb of AR was detected by HPLC analysis.

No attempt was made to identify the minor transformation products observed in the study since they comprised <2.7% of the applied radioactivity, at any interval.

The rate of degradation was not determined for BYI 02960 since minimal degradation was observed in the pH 4, 7 and 9 buffer solutions.

Results

Data

All buffer solutions (pH 4 = acetate, pH 7 = tris, pH 9 = borate) had a concentration of < 0.01 M. The measured average pH of the buffers was 3.94, 6.89 and 8.99, respectively. Sterility was maintained throughout the study with the exception of a single time point in a single pH. The Day 4, pH 9.0, replicate 1 and 2 samples gave a positive result (sterility was lost) on the aerobic count plate. The samples were analyzed by HPLC to determine if a lack of sterility was an issue. The results showed comparable results to the other test system (stable), thus the lack of sterility did not impact results.

The test systems were maintained in the dark, in a covered water bath held at 50.1 ± 0.13°C (minimum = 49.7°C, maximum = 50.3°C). The resulting data based on LSC and analyses are shown in Table B.8.4.1-01 to Table B.8.4.1-03.

Mass Balance

For this study the AR (100% of applied radioactivity) was defined as the amount of radioactivity recovered in the day 0 sample (mean of label #1 and #2). Based on the results of LSC an RA balance was established for each buffer solution at each sampling interval. A summary of the total recoveries of the radioactivity is given in the following tables.

The mean material balance for pH 4 buffer ranged from 95.8 - 100.9% of AR, with a mean of 98.8% (Table B.8.4.1-01). The mean material balance for pH 7 ranged from 95.0 - 102.7% of AR, with a mean of 99.9% (Table B.8.4.1-02). The mean material balance for pH 9 ranged from 100.3 - 101.2% of AR, with a mean of 100.7% (Table B.8.4.1-03). Individual values are provided for pH 4, 7 and 9 in the report. Adsorption of the test compound to the test vessels was not indicated based on the material balances. The complete material balances found in all solutions demonstrated that no radioactivity dissipated from the solutions by means of volatilization or was lost during sampling/processing.

Bound and Extractable Residues

Not applicable

Volatilization

Since the test system was sealed and a loss in material balance was not observed, no attempt was made to trap volatiles.

Transformation of test item

The amounts of BYI 02960 and degradates were quantified by HPLC. The results for all tests, expressed as percent AR, are given in tables above. Throughout, the concentration of parent compound remained almost constant from day 0 to day 5, with 96.2 - 92.1% of AR at pH 4, 94.5 - 96.6% of AR at pH 7, and 95.8 - 95.8% of AR at pH 9, respectively.

Minimal degradation of the parent compound occurred at all three pH values. No major transformation products were formed at any pH. Three minor degradates “Unknown A, B and C” at maximum amounts of 2.7% of AR.

Kinetics of Test Item Degradation

The rate of degradation was not determined for BYI 02960 since minimal degradation was observed in the pH 4, 7 and 9 buffer solutions. Thus, BYI 02960 can be considered to be hydrolytically stable under environmental conditions.

Conclusions

From the current laboratory study it is concluded that hydrolysis is not relevant for the degradation of BYI 02960 in the environment, and that a further study with another radiolabel is not needed.

Remarks

The study clearly indicates that BYI 02960 is hydrolytically stable under environmental conditions. The RMS agrees with the applicant that no further studies with other radiolabels are required. The results are acceptable and were also evaluated under study IIA, 2.9.1/01.

B.8.4.2 Photolytic degradation (Annex IIA 7.2.1.2) OECD number 7.6

In accordance with points IIA, 2.9.2 and IIA, 2.9.3, tests on photolysis (direct photo-transformation) of BYI 02960 in water are also presented here to provide a complete and comprehensive overview on the fate and behaviour of this substance in this corresponding section B.8.4 of the dossier. For the respective route of phototransformation study (compare study IIA 2.9.2) radiolabeled FUR BYI 02960 was investigated in pure buffers. A summary of these studies is repeated here, focusing on formation and degradation of transformation products. In addition, the determination of the quantum yield of direct phototransformation in water and the derived environmental half-lives in surface water are also given for the active substance. Further a supplementary study on the phototransformation of BYI 02960 in natural water is submitted and presented.

STUDY IIA, 7.6/01

Characteristics

reference	:	Hall, L.R., 2011	incubation time	:	up to 35 hours

year of execution	:	2010	pH/temperature	:	pH 7/temp 25°C
GLP statement	:	Yes	light intensity	:	680 W/cm2
guideline	:	OPPTS 835.2240, 2008; Japanese JMAFF New Test Guidelines, 2000 Canada PMRA DACO Number 8.2.3.3.2	conclusion	:	photolytic DT_{50} under study conditions 13.8 hours
test substance	:	[furanone-4-^{14}C] BYI 02960	acceptability	:	**Acceptable**
purity	:	radiochemical purity 99.3%			

Summary

The aqueous phototransformation of [FUR-^{14}C] BYI 02960 was studied at 25°C in sterile buffer (pH 7) at an initial concentration of approx. 1.0 mg a.i./L under artificial irradiation (xenon lamp, >290 nm, quartz and Suprax® filter) for 35 hours. At this timepoint the DT_{75} for BYI 02960 was exceeded.

Duplicate irradiated test systems and single dark control test systems were analyzed at 0, 4, 8, 12, 16, 22, 28, and 35 hours by direct injection of samples into HPLC. Identification of parent and major transformation products was accomplished by co-elution with authentic reference standards, LC/MS and/or NMR analysis.

The anticipated test conditions (temperature, sterility and pH 7) were maintained, and material balances for the irradiated and dark test systems were complete throughout the study. In the dark test systems (i.e. the controls), BYI 02960 was found to be stable.

In the irradiated test systems, BYI 02960 decreased from 98.1% of AR at time 0 (mean of replicates) to 8.4% of AR at 35 hours of irradiation. The major degradates included BYI 02960-succinamide (max. 39.6% of AR at 28 hours) and BYI 02960-azabicyclosuccinamide (maximum 25.9% of AR at 35 hours). A minor degradate was identified as BYI 02960-deschlorohydroxysuccinamide (DCHS, maximum of 2.5% at 35 hours) which is considered as intermediate between the two major photodegradates. No other single detected component exceeded 3% of AR at 35 hours.

The first-order half-life for photolytic degradation of BYI 02960 in sterile buffer of pH 7 was 13.8 experimental hours. Based on this experimental half-life of BYI 02960, the direct phototransformation half-life in top layer of surface water is calculated to be 1.75 days under environmental sunlight conditions in Phoenix, AZ, USA (latitude 33.3°N) and 2.7 days in Athens, Greece (latitude 38.03N).. Based on this finding, BYI 02960 should rapidly degrade in the aqueous environment if exposed to sunlight.

Table B.8.4.2-01 Half-life, DT_{75} and DT_{90}

Test System	Kinetic Model	Equation	χ^2 test error (%)	Experimental hours		
				DT_{50}	DT_{75}	DT_{90}
Irradiated	SFO	$M_{(t)} = 103.3^{-0.0503\,t}$	10.4	13.8	27.6	45.8
Dark	SFO	$M_{(t)} = 99.7e^{-(1.2e-10)\,t}$	0.50	>>1000	nc	Nc

nc = not calculated since compound is stable

Materials and Methods

Materials

1. Test Item: Code BYI 02960, CAS no. 951659-40-8 (unlabelled substance); Label position = [Furanone-4-^{14}C] BYI 02960 (vial No. C-1116); Specific activity: 30.74 mCi/mMole (3.94 MBq/mg) Radiochemical purity: 99.3% (at beginning of study);Identity and purity of test item in the application solutions were checked.

2. Test system: The irradiated test system consisted of 20 mL of filter-sterilized sterile buffer (pH 7) treated with BYI 02960 at ~1.0 µg/mL and sealed in a quartz glass vessel. The dark control test systems consisted of 20 mL of filter-sterilized buffer (pH 7) treated with BYI 02960 at ~1.0 µg/mL and crimp-sealed in a 20-mL amber bottle.

3. Test matrix: The test matrix for this study was comprised of sterile 10 mM potassium phosphate buffer (pH 7). Buffer was prepared by dissolving 2.72 g of potassium dihydrogen phosphate in ~1.9 L of water. The pH was adjusted to 7 by the addition of 1 M potassium hydroxide. After adjustment to pH 7, the buffer was diluted to 2.0 L and thoroughly mixed. The buffer was stored at room temperature overnight and used immediately the following morning.

Methods

1. Experimental conditions: Twenty four test systems were prepared for irradiation. Duplicate test systems were prepared for each of the nine planned sampling intervals as well as six spare test systems for additional sampling intervals or for unforeseen losses. Each quartz glass vessel was filled with 20 mL of filter-sterilized sterile buffer (pH 7) containing approximately 1.0 µg/mL of test substance. Ten control test systems were prepared and were maintained in the dark at 25 ± 1°C in an incubator.

2. Application procedures: Treated buffer (pH 7) was sterilized by passing it through a 0.22-µm sterile filter into each autoclaved test vessel using aseptic techniques in a laminar flow hood. The amount of water added to each vessel was determined by the weight (approximately 20 g) added to a tared vessel. The irradiated test vessels were closed with ground glass stoppers. The quartz photolysis vessels were placed in a Suntest CPS unit containing a Heraeus xenon-arc lamp. Light emission was filtered using a Suprax® filter that eliminated wavelengths <290 nm. For the dark control test systems, the same amount of treated sterile buffer (pH 7) was filter-sterilized and transferred into sterile amber bottles which were sealed with crimp caps.

The test substance concentration was 1.11 µg/mL which is much less than half of the water solubility of BYI 02960 at pH 7 (water solubility is 3.2 mg/mL).

3. Sampling: Duplicate irradiated test systems and individual dark control test systems were analyzed at 0, 4, 8, 12, 16, 22, 28, and 35 hours post treatment. All test systems were checked for pH and sterility. Samples were immediately analyzed after removal from either the incubator or the Suntest.

4. Analytical procedures: Triplicate aliquots (100 µL) from each test system were radioassayed. For all samples, a 1-mL aliquot was removed and used for sterility testing. An aliquot (approximately 4 mL) was transferred to an HPLC autosampler vial, and the remaining test solution was transferred to a glass vial. All samples were directly analyzed by HPLC (1 mL injection) without any concentration or extraction.

Major degradates, including the parent compound, were either isolated by HPLC from an MID sample or a kinetic sample was analyzed directly by LC/MS. Collected fractions were dissolved in water and analyzed by LC/MS. Some degradates were isolated and analyzed by high resolution MS and NMR.

Results

Data

The target temperature of 25 ± 1°C was maintained during the study, and the mean pH of the water was 6.99 in the irradiated systems and 7.01 in the dark test systems. Sterile conditions were maintained in all test systems. The irradiated systems were continuously exposed to artificial sunlight with an intensity of 680 W/m^2 for a period of 35 hours. The analytical results of the study are presented in Table B.8.4.2-02.

Mass Balance

The mean material balance of the irradiated [^{14}C] BYI 02960 test systems was 100.6% and ranged from 99.3 to 101.6% in individual systems. The mean material balance for the dark control test systems was 101.1% and ranged from 99.6 to 101.4% in individual test systems.

Bound and Extractable Residues

Not applicable.

Volatilization

No attempt was made to trap volatiles. This was justified since the mass balances were complete throughout the study.

Transformation of Test Item

Four radioactive components exceeded 10% of AR at any interval, one of these was [^{14}C] BYI 02960. Two major degradates were identified as BYI 02960-succinamide and BYI 02960-azabicyclosuccinamide. The fourth region that exceeded 10% of AR was a group of components ("polar mixture") which eluted early in the chromatogram in reverse-phase HPLC. By TLC it was shown to consist of multiple components, and no single component exceeded 3% of the applied radioactivity at 35 hours. One minor degradate was identified as BYI 02960-dechlorohydroxy-succinamide (DCHS) by comparison to a synthetic standard.

Table B.8.4.2-02 Phototransformation of [^{14}C] BYI 02960 in irradiated test systems (mean ± SD) as a percentage of applied radioactivity (1)

Compound	Sampling times [hours]			
	0	4	8	12

(4) Minor others is comprised of several compounds, none of which comprised >7% of the applied radioactivity at any interval

Kinetics of the test item degradation

Half-life, DT_{75} and DT_{90} of [^{14}C] BYI 02960 are presented in Table B.8.4.2-03. The first-order half-life for photolytic degradation of BYI 02960 in sterile buffer of pH 7 was 13.8 experimental hours. Based on this experimental half-life of BYI 02960, the direct phototransformation half-life in top layer of surface water is calculated to be 1.75 days under environmental sunlight conditions, e.g. in Phoenix, AZ, USA (latitude 33.3°N), 2.7 days in Athens, Greece (latitude 38.03N) and 3.4 days in London, UK (51.32 N). Based on this finding, BYI 02960 should rapidly degrade in the aqueous environment if exposed to sunlight.

Table B.8.4.2-03 Half-life, DT_{75} and DT_{90}

Test System	Kinetic Model	Equation	χ^2 test error (%)	Experimental hours			Equivalent days in Phoenix, AZ; USA		
				DT_{50}	DT_{75}	DT_{90}	DT_{50}	DT_{75}	DT_{90}
Irradiated	SFO	$M_{(t)} = 103.3^{-0.0503\,t}$	10.4	13.8	27.6	45.8	1.8	3.5	5.8

nc = not calculated since compound is stable

Conclusions

[^{14}C] BYI 02960 photolytically degraded in sterile buffer (pH 7) with a half-life of 13.8 experimental hours. Based on this finding, BYI 02960 should degrade within a few days in the aqueous environment if exposed to sunlight. The major degradates (>10% of applied radioactivity) were identified as [^{14}C] BYI 02960-succinamide and [^{14}C] BYI 02960-azabicyclosuccinamide. The findings were included in the proposal for the pathway of degradation of BYI 02960 in an aqueous environment (see Figure B.8.4.4-01).

Remarks

The study is acceptable and results are reliable. Only the FUR BYI 02960 was tested and not an other radiolabel. The other ring structure is also photolytically active. A test with this radiolabel might result in different metabolites. Therefore, in principle PYR BYI 02960 should also be tested. However, for BYI 02960 (flupyradifurone) in the aqueous photolysis study, two major degradates BYI 02960-succinamide and BYI 02960-azabicyclosuccinamide were identified and contained the same number of carbons as the parent compound as demonstrated in the pathway. Thus the bond between the two rings (furanone and chloropyridine) was not broken during the course of this study. In addition, the bond between the difluoroethyl side chain and the amino moiety remained intact. Therefore conducting this study with only one radiolabel position is sufficient for tracking all the major degradates formed in the photolyis of BYI 02960.

STUDY IIA, 7.6/02

Characteristics

guideline	:	Phototransformation of Chemicals in	quantum yield	:	Φ = 0.000138

		Water, Part A: Direct Phototransformation, UBA, Berlin, Germany (Dec 1992); Test Method: ECETOC (Polychromatic Light Source)			
test substance	:	BYI 02960	acceptability	:	**acceptable**
purity	:	99.4%			

Summary

The quantum yield of direct phototransformation of BYI 02960 was determined in aqueous solutions using polychromatic light according to the ECETOC method. Degradation of BYI 02960 in aqueous solution of ≤10% was measured by HPLC-UV after a maximum irradiation period of 500 minutes. This indicated moderate degradability of BYI 02960 via direct phototransformation in aqueous and buffered solutions. A mean quantum yield of Φ = 0.000138 was calculated on the basis of UV absorption data and the degradation kinetics determined from both experiments.

The estimates based on the two modelling concepts (Zepp & Cline or Frank & Kloepffer) are comparable. Both estimates consider the quantum yield Φ and the absorption in the UV-VIS spectrum being in the range of wavelengths relevant for the environment (see tables below). Environmental direct phototransformation half-lives of BYI 02960 in sunlight exposed surface water layers are estimated to in a range of 10 to 14 days during periods of main use, i.e. in spring to summer.

Thus, direct phototransformation in aqueous solution may contribute to the dissipation of BYI 02960 from the environment. This assessment does not consider other potential mechanisms which may enhance the degradation in natural water, e.g. by indirect photolytic processes.

Table B.8.4.2-04 Zepp and Cline modelling using GC Solar program

Season	Environmental DT_{50} of Direct Phototransformation of BYI 02960 [days]			
	30th degree lat.	40th degree lat.	50th degree lat.	60th degree lat.
Spring	11.4	12.2	13.6	16.2
Summer	10.3	10.3	10.7	11.3
Fall	15.9	20.2	29.5	54.2
Winter	21.2	32.2	63.2	195

Marginal conditions: pure surface water at 0-5 cm depth, 10th degree longitude, clear sky, typical ozone concentrations in the atmosphere, half-lives integrated over the entire day. The columns of the 40-50th degree of latitude is more or less relevant to the conditions of Europe.

Table B.8.4.2-05 Frank and Kloepffer modelling (MEF-11/554)

Month	Photolysis Constant [1/sec]	Environmental DT_{50} of Direct Phototransformation of BYI 02960 [days]		
		Minimum	Mean	Maximum
January	0.501×10^{-7}	76	160	730
February	0.104×10^{-6}	37	77	340
March	0.203×10^{-6}	21	40	160
April	0.340×10^{-6}	13	24	94
May	0.434×10^{-6}	12	18	74
June	0.486×10^{-6}	11	17	66
July	0.433×10^{-6}	12	19	62

August	0.423×10^{-6}	13	19	63
September	0.246×10^{-6}	19	33	120
October	0.135×10^{-6}	31	59	270
November	0.601×10^{-7}	58	130	670
December	0.316×10^{-7}	120	250	1300

Marginal conditions: pure stagnant surface water at 0-5 cm depth, geographic and climatic conditions of Germany (50th degree latitude); no contribution of another mono- or bimolecular elimination process.

Materials and Methods

Materials

1. Test Item:Common name: Flupyradifurone (CAS no. 951659-40-8); Chem. Code: BYI 02960; Sample ID: AZ16895, Batch NLL7780-47-4; Certified assay: 99.4% w/w.

2. Test Solutions: The study was conducted using highly pure water (taken from a TKA-Genpure unit): conductivity = 0.055 µS; TOC = 2 ppb. UV-VIS spectra were measured in 0.01 M aqueous buffer solutions (acetate pH 4, phosphate pH 7 and borate pH 9). A solution containing 5.03 mg BYI 02960 (1.74×10^{-5} mol)/L pure water was prepared for irradiation experiments.

Methods

The quantum yield for direct phototransformation of BYI 02960 in aqueous solution was determined in a merry-go-round apparatus (Type 13/150 Mangels Co.) that was equipped with a mercury arc lamp (Type TQ 150 Original Hanau Co.) in a Duran® 50 filter and cooling finger. The filter absorbed light with a wavelength below 290 nm and let pass the polychromatic light above this cut-off wavelength. The merry-go-round irradiation apparatus is warmed up for at least 15 minutes prior to the exposure of the samples in order to guarantee a constant radiation of the light source as well as the projected sample temperature of 25°C ± 1°C at the beginning of the experiment. Subsequently, only the merry-go-round but not the lamp or the cycle cooling is switched off for adding or removing samples.

After equilibration, two measuring cells with 3.0 mL of actinometer solution (A) are first exposed to the light in the system for 10 minutes. The measuring cells containing 3.0 mL of test solution are swiftly placed onto the 10 positions of the merry-go-round apparatus. At the respective sampling interval a single sample is removed. Finally, *i.e.* after both degradation experiments were finished, two samples with solution (A) were irradiated and used for actinometry.

The results of BYI 02960 analysis (usually means of duplicates) were evaluated on the basis of linear regression in order to receive the time (in minutes) after which 10% of the molecules of the test item have been degraded. That value is necessary to calculate the quantum yield of phototransformation.

Results

Data

Intensity of irradiation was calculated to 6.023 x 10^{16} (experiment #1) and 6.1599 x 10^{16} (experiment #2) photons absorbed per second for the 3 mL actinometry solution in the range of wavelength from 295 to 490 nm. Phototransformation results are presented in Table B.8.4.2-06.

Table B.8.4.2-06 Phototransformation of BYI 02960 in water

Duration of Irradiation [min]	Experiment #1 BYI 02960 [mg/L]	Experiment #2 BYI 02960 [mg/L]
0	5.03 (= 100%)	5.03 (= 100%)
50	4.90	4.97
100	4.89	4.91
150	4.93	4.87
200	4.89	4.83
250	4.81	4.83
300	4.71	4.77
350	4.72	4.79
400	4.64	4.70
450	4.58	4.61
500	4.56 (= 90.7%)	4.69 (= 93.2%)

A degradation of BYI 02960 of 7 and 10% was determined by HPLC-UV after a maximum irradiation period of 500 minutes. This indicated moderate photostability of BYI 02960 in the aqueous buffered solution.

Based on both degradation experiments quantum yields Φ of 1.5538 x 10^{-4} (experiment #1) and 1.1983 x 10^{-4} (experiment #2) were calculated. Environmental half-lives were calculated according to Zepp & Cline and Frank & Kloepffer (see Table B.8.4.2-04 and Table B.8.4.2-05).

Conclusions

A mean quantum yield of direct phototransformation of Φ = 0.000138 was calculated for BYI 02960 on the basis of UV absorption data and the degradation kinetics determined from both experiments. Thus, direct phototransformation in aqueous solution may contribute to the dissipation of BYI 02960 from the environment. A comparison of the estimates derived from models of Zepp & Cline and Frank & Kloepffer shows that both approaches are well comparable. Environmental direct phototrans-formation half-lives of BYI 02960 in sunlight exposed surface water layers are estimated to in a range of 10 to 14 days during periods of main use, i.e. in spring to summer.

However, this assessment does not consider any other potential mechanisms which may enhance the degradation in unpurified water, i.e. caused by indirect photolytic processes. Maybe such was the difference to the kinetics result of the earlier study not performed in pure water but in buffer (study IIA, 7.6/01). Thereby, BYI 02960 degraded faster, i.e. with an estimated DT_{50} of just a few days in an aqueous environment if exposed to sunlight.

Remarks

The study is acceptable.

STUDY IIA, 7.6/03

Characteristics

reference	:	Hall, L.R., 2011	incubation time	:	28 hours
study type	:	aqueous photolysis in sterile natural water	nominal concentration	:	1 mg/L
year of execution	:		pH/temperature	:	8.2 / 25°C
GLP statement	:	Yes	light intensity	:	680 W/cm^2
guideline	:	JMAFF (2000)	conclusion	:	DT_{50} in sterile buffer pH 7 14 hours days, equivalent to <3.8 calendar days at Tokyo (35°N)
test substance	:	[furanone-4-^{14}C] BYI 02960	acceptability	:	**acceptable**
purity	:	radiochemical purity 99.3%			

Summary

The aqueous phototransformation of [FUR-^{14}C] BYI 02960 was studied at 25°C in sterile natural water at an initial concentration of 1 mg a.i./L under artificial irradiation (xenon lamp, >290 nm, quartz and Suprax® filter) for max. 28 hours, equivalent to max 7.5 environmental days at Tokyo, Japan. This duration of irradiation exceeded the DT_{75} for BYI 02960 in the experiment. Duplicate irradiated and single dark test systems were analyzed at 0, 4, 8, 12, 16, 22 and 28 hours by direct injection of samples into HPLC. Identification of parent and major transformation products was accomplished by co-elution with authentic reference standards, LC/MS and/or NMR analysis.

The anticipated test conditions (temperature and sterility) were maintained, and material balances for the irradiated and dark test systems were complete throughout the study. In the dark test systems (i.e. the controls), BYI 02960 was found to be stable, showed very little degradation at pH 8 and 25°C.

In the irradiated test systems, [^{14}C] BYI 02960 degraded from 95.1% of AR at time 0 (mean of replicates) to 17.2% of AR after 28 hours of irradiation. The major degradates included BYI 02960-succinamide (max. 38.2% at 28 hours) and BYI 02960-azabicyclosuccinamide (max. 14.3% at 28 hours). A minor degradate was identified as BYI 02960-deschlorohydroxysuccinamide (maximum of 2.2% at 22 hours) and is considered an intermediate leading to the formation of BYI 02960-azabicyclosuccinamide. A group of components ("polar mixture") that eluted near the HPLC column's void volume was shown by TLC to consist of multiple components, and none of these components exceeded 7.3% of the applied radioactivity.

The first-order half-life for photolytic degradation of BYI 02960 in the natural water was 14.0 experimental hours. Based on this value the half-life of BYI 02960 under environmental conditions is calculated to be, e.g., 3.8 days at Tokyo, Japan (latitude 35°N). Thus, phototransformation in aqueous solution contributes very well to the dissipation of BYI 02960 from the environment. Therefore, the findings were included in the proposal for the pathway of degradation of BYI 02960 in an aqueous environment (see Figure B.8.4.4-01).

Materials and Methods

Materials

1. Test Item: Flupyradifurone: Code = BYI 02960; CAS no. 951659-40-8 (unlabeled); Designation of label: [furanone-4-^{14}C] BYI 02960 or [FUR-^{14}C] BYI 02960; Specific Activity: 30.74 mCi/mmol (~236,400 dpm/µg; 3.94 MBq/mg); Radiochemical Purity: 99.3%

2. Test System: The test matrix for this study was comprised of natural water collected on March 29, 2010 from the lake at Heritage Park, Olathe (Johnson County), Kansas. Water was collected at the surface, 0-6 inches deep. The natural water was stored at room temperature overnight and used immediately the following morning.

Table B.8.4.2-07 Physicochemical characteristics of unfiltered natural water

Parameter	Results/Units
pH	8.2
Dissolved oxygen	8.43 mg/L
Calcium	67 mg/L (ppm)
Magnesium	12 mg/L (ppm)
Hardness ($CaCO_3$ equivalent)	217 mg/L
Electrical conductivity	0.88 mmho/cm
Total Dissolved Solids	486 mg/L (ppm)
Turbidity	3.53 NTU
Alkalinity	158 mg $CaCO_3$/L
Total Organic Carbon	4.3 mg/L (ppm)
Dissolved Organic Carbon	3.7 mg/L (ppm)
Carbonates	0.58 meq/L
Bicarbonates	2.16 meq/L
Total Nitrogen	1.1 mg/L (ppm)
Total Phosphorus	0.9 mg/L (ppm)

Methods

1. Experimental conditions: The tests were performed using individual static test systems held at aerobic conditions at 25 ± 1 °C for a period of 6 experimental days. They consisted of 24 quartz glass vessels [50 mm x 25 mm x 15 mm (height)] each containing 20 mL of the test solution (buffer solution + 1.0 µg/mL test item), and were closed (except in case of time 0) with a trap attachment (permeable for oxygen) containing soda lime for absorption of $^{14}CO_2$ and a polyurethane foam plug for adsorption of volatile organic compounds. The test systems were either incubated in the dark as controls or continuously exposed to artificial irradiation (Suntest® unit equipped with a xenon lamp and <290 nm cut-off filter). The Suntest unit was operated at approximately 680 W/m^2 (290-800 nm) to simulate highly photoreactive conditions. At this intensity it would take 3.71 hours in the Suntest unit to equal one solar day in Tokyo, Japan. Since 3.71 hours represents 1 environmental day, 111.4 hours (4.64 days) of continuous irradiation at 680 W/m^2 is equivalent to 30 environmental days.

2. Sampling: Duplicate irradiated test systems and individual dark control test systems were analyzed at 0, 4, 8, 12, 16, 22, and 28 hours post treatment. All samples were immediately analyzed after removal from either the incubator or the Suntest, with analyzes completed within 3 hrs. Volatile traps were not used.

3. Description of analytical procedures: The radioactivity of the test solutions was radio-assayed by triplicate 100-µL aliquots. All samples were directly analyzed by HPLC without any concentration or extraction. Identification and confirmation of the parent compound and transformation products was done by co-chromatography (LC-MS/MS and NMR techniques).

Determination of Degradation Kinetics

The photolytic degradation of BYI 02960 in the natural water was characterized using kinetics modelling. A simple first order (SFO) model was used for determination of rate constants. The mean percentage (two replicates) of applied radioactivity as BYI 02960 of two replicates at all sampling times was used to determine the degradation rate and kinetic endpoints (modelling tool MATLAB (Ver. 7.0.4)).

Results and discussion

Data

The pH of the test solutions was about pH 8 at the beginning irradiated and dark test systems. The test water was maintained sterile throughout the test period. The 22-hr dark control (sample 5C) showed the presence of seven colony forming units. However, this contamination did not have a significant impact on the degradation of BYI 02960 since the percentage of parent in the dark control sample at 22 hours was slightly higher than the percentage of parent in either the 16 or 28-hour samples.

Mass Balance

The mean material balance of the irradiated test systems was 98.1% and ranged from 95.7 – 99.7% in individual test systems (see Table). The mean material balance for the dark control test systems was 98.5% and ranged from 97.1 – 99.8% in individual test systems.

Transformation of Test Item

Irradiated samples: During the study, the concentration of [^{14}C] BYI 02960 in irradiated test systems decreased from 95.1 to 17.2% of the theoretical applied amount of radioactivity (mean of replicates) after 28 hours (see Table B.8.4.2-08). Only two degradates exceeded 10% of AR in 28 hours in the irradiated test systems. The major degradate was identified as [^{14}C] BYI 02960-succinamide which reached a max. of 38.2% of AR after 28 hours. [^{14}C] BYI 02960-azabicyclosuccinamide reached a max. of 14.3% of AR after 28 hours. A group of radioactive components eluted near the solvent front by HPLC in the irradiated samples (polar regions 1 and 2). These two regions were collected together and reanalyzed by TLC which showed that the polar region was comprised of many components present at low levels**.** No single component in the polar region comprised more than 7.3% of AR at 22 hours or 4.5% of AR at 28 hours. A minor degradate, [^{14}C] BYI 02960-deschlorohydroxysuccinamide, was identified by LC/MS comparison to a synthetic standard. The max. concentration of BYI 02960-deschloro-hydroxysuccinamide was 2.2% of AR at 22 hours.

Dark control samples: In the dark test systems, [^{14}C] BYI 02960 was more or less constant (98.0 and 96.0% (single values) after 28 hours. No single degradate exceeded 0.8% of the applied radioactivity at any sampling interval.

(1) Ppb analyte can be calculated as follows: Ppb analyte = Analyte as % of applied x (ppb parent applied ÷ 100%) x (MW analyte/MW parent); MW of BYI 02960 = 288.7
(2) DCHS – BYI 02960-deschlorohydroxysuccinamide – intermediate between BYI 02960-succinamide and BYI 02960-azabicyclosuccinamide
(3) Polar regions combined and analyzed by TLC. No single component comprised >3% of the applied radioactivity

Kinetics of Test Item Degradation

Degradation kinetics of [^{14}C] BYI 02960 (DT_{50}, DT_{75}, and DT_{90}) is shown in Table B.8.4.2-09.

Table B.8.4.2-09 BYI 02960 degradation kinetics

Test System	Kinetic Model	Equation	χ^2test error (%)	Experimental hours			Equivalent days, at Tokyo, JAP		
				DT_{50}	DT_{75}	DT_{90}	DT_{50}	DT_{75}	DT_{90}
Irradiated	SFO	$M_{(t)} = 101.7e^{-0.0495\,t}$	10.7	14.0	28.0	46.5	3.8	7.5	12.5
Dark	SFO	$M_{(t)} = 98.2e^{-0.00062\,t}$	0.50	1118	>2200	>3700	46.6	>92	n/a

Conclusions

BYI 02960 photolytically degraded in sterile natural water with a half-life of 14.0 experimental hours. The major degradates (>10% of AR) were identified as BYI 02960-succinamide and BYI 02960-azabicyclosuccinamide. A minor degradate was identified as BYI 02960-deschlorohydroxy-succinamide. In the dark controls BYI 02960 was stable. Based on the experimental half-life of 14.0

hours, the half-life of BYI 02960 under environmental conditions in Tokyo, Japan was calculated to be 3.8 days. The phototransformation study in natural water is regarded more relevant for the aqueous environment as the pure buffer study (compare study IIA, 7.6/01). The following data represent the synopsis for phototransformation of BYI 02960, and the findings were included in the proposal for the pathway of degradation of BYI 02960 in an aqueous environment (see Figure B.8.4.4-01).

Table B.8.4.2-10 Result Synopsis

Test substance	**[Furanone-4-^{14}C] BYI 02960**
Test medium	Sterile natural water from lake in Heritage Park, Olathe, Kansas.
Source of irradiation	Xenon lamp with cut-off filter to remove light of waves <290 nm
Experimental DT_{50} in Suntest	14.0 hours
Environmental DT_{50}, e.g. in Tokyo, Japan	3.8 days
Dark control DT_{50} in Tokyo, Japan	>46 days. Very little degradation observed
Major transformation products after irradiation: BYI 02960-succinamide BYI 02960-azabicyclosuccinamide 	
Minor transformation products after irradiation BYI 02960-deschlorohydroxysuccinamide 	
Total number of photodegradates formed by irradiation	At least 18 compounds formed, but only two products exceeded 10% of applied radioactivity.
Total number of degradates observed in dark control samples	Maximum of 3 degradates observed, and all were <1%.

Remarks

The RMS evaluated the photolysis study and agrees that photolysis is an important process in the aqueous environment. No major difference caused by indirect photolysis. Results ar not used for EU risk assessment.

B.8.4.3 Biological degradation

Biological degradation of BYI 02960 in aquatic systems was investigated in studies on anaerobic and aerobic biodegradation under dark laboratory conditions using natural water-sediment systems. Results also relevant for the behavior of BYI 02960 in natural water, i.e. those of the abiotic hydrolysis and aqueous photolysis study in water, were shown in studies IIA 7.5/01 and IIA, 7.6/01 to IIA, 7.6/02, already. All those findings are considered for the overall pathway of BYI 02960 in water shown by Figure B.8.4.4-01.

B.8.4.3.1 Ready biodegradability (Annex IIA 7.7)

A respective study was not performed. The parent compound BYI 02960 is considered to be "Not Readily Biodegradable.

B.8.4.3.2 Degradation in water-sediment systems (Annex IIA 7.8)

STUDY IIA, 7.8.2/01

Summary

The anaerobic biotransformation of [pyridine-2,6-^{14}C] BYI 02960 was studied in two pond water/sediment systems. One system was collected from a pond near Lawrence, KS, USA and the other was taken from a pond in Pikeville, NC, USA. The study was conducted for 102 days in the dark at 24 ± 2 °C. BYI 02960 was applied at a rate of 0.233 and 0.203 mg a.i./L for Lawrence, KS and Pikeville, NC. The treatment rate was based an application rate of 410 g a.i./ha. The test systems consisted of an Erlenmeyer flask containing 50 g (dry weight) sediment and 150 mL pond water, i.e. a sediment/water ratio of 1:3. Eight sampling intervals were conducted and included 0, 7, 14, 21, 29, 43, 70 (71 for Pikeville, NC), and 102 days post treatment. The water samples were filtered and analyzed by direct sample injection into HPLC. The sediment was extracted sequentially at ambient temperature, followed by two aggressive extractions using a microwave extractor at 70 ºC. Appropriate volumes of both the ambient and aggressive extracts were concentrated and analyzed by HPLC coupled to a ^{14}C detector to characterize ^{14}C-BYI 02960 residues. Identification of the BYI 02960 was achieved by co-chromatography and liquid chromatography-electrospray ionization mass spectrometry (LC-ESI/MS).

The anticipated test conditions (incubation temperature, anaerobicity and microbial viability) were maintained, and material balances for both test systems were complete throughout the study.

<u>Lawrence test system</u>: The radioactive residues in the water phase decreased from an average of 99.1% at Day 0 to 48.6% at Day 7 and declined to 25.1% at the end of the study (Day 102). The radioactive residues in the sediment increased from an average of 8.8% on Day 0 to 46.8% at Day 7 and increased to 70.4% at Day 43, and 68.9% at the end of the study. Unextractable residues were increasing from 0.2% at Day 0 to 4.9% at the end of the study. Volatile compounds remained low with $^{14}CO_2$ ≤0.1% and organic volatiles below the LOQ. No major degradates were formed in the test systems with Lawrence, KS sediment. Total minor unidentified ranged from 1.3 – 5.3% throughout the study.

Pikeville test system: The radioactive residues in the water phase decreased from an average of 87.3% at Day 0 to 48.4% at Day 7 and further declined to 18.5% by the end of the study (Day 102). The radioactive residues in the sediment increased from an average of 11.4% on Day 0 to 49.2% at Day 7 and continued to increase to 78.7% at Day 71 and 64.8% at the end of the study. Unextractable residues were increase from 0% at Day 0 to 12% at the end of the study. Volatile compounds remained low with $^{14}CO_2$ ≤0.1% and organic volatiles below the LOQ. No major degradates were formed in the test systems. Total minor unidentified ranged from 0.0 -. 0.7% throughout the study.

Kinetics: BYI 02960 dissipated from the water phase to the sediment with a half-life of 7.2 and 9.6 days for Lawrence and Pikeville test system, respectively. The half-lives of BYI 02960 in the sediment under anaerobic conditions were 415 days for Pikeville sediment and greater than 1000 days for Lawrence sediment. Thus the compound is regarded as stable under anaerobic conditions.

Materials and Methods

Materials

1. Test Item: [Pyridine-2,6-^{14}C] BYI 02960; Sample ID: C-1135; Specific activity = 269,387 dpm/µg (35.03 mCi/mMole); Radiochemical purity: 99%

2. Test system: The test matrices used in this study were a water/sediment collected from pond near Lawrence, KS, USA (water: pH 8.3, sediment: texture silty clay, pH 7.7 (saturated paste), OC% 1.1) and the other was taken from a pond in Pikeville, NC, USA (water: pH 7.4; sediment: texture loamy sand, pH 5.1 (saturated paste), OC% 1.5). The top 6 inches of sediment were collected using a shovel. Description of the test matrix collection and storage data is given in Table B.8.4.3.2-01. Selected physico-chemical characteristics of water are presented in Table B.8.4.3.2-02, and of sediment in Table B.8.4.3.2-03.

Methods

1. Experimental conditions: Each twenty-two kinetics test systems were treated. In addition, 6 test systems were dosed at 4 times the kinetic rate for the NC sediment and 5 for KS sediment to be used for identification of metabolites. Seven additional test systems for each sediment/water system were used as controls for determining biomass at the beginning and end of the study. The experimental design is depicted in Table B.8.4.3.2-04.

Table B.8.4.3.2-01 Description of water and sediment collection and storage

Parameter	Lawrence, KS	Pikeville, NC
Geographic location	350 Wild Horse Road, Lawrence, KS	703 Nor AM Road, Pikeville, NC

Parameter	Description

Duration of test		102 days
Water		2-mm sieved
Sediment		2-mm sieved
Sample Size	Water: Sediment:	150 mL 50 g (dry weight)
Water:Sediment ratio		3:1
Test concentrations	mg a.i./L water mg a.i./kg sediment mg a.i./kg total system	0.233 (KS), 0.203 (NC) 0.700 (KS), 0.608 (NC) 0.175 (KS), 0.152 (NC)
Control conditions (if used)		24 ± 2 °C, dark
Number of replications per interval	Treatments	2
	Control (untreated)	0
Test apparatus		250-mL Pyrex Erlenmeyer flask with side-arm and double-valve sealable top (or mineral oil bubblers during pre-incubation).
Traps for CO_2 & organic volatiles		2 N KOH, ethylene glycol, 1 M H_2SO_4
Test material application	Identity of solvent	Methanol (< 0.1%)
	Volume of test solution used per test system	0.230 mL (KS) 0.190 mL (NC)
	Application method	250-µL Hamilton syringe to water surface
	Evaporation of application of solvent	No
Indication of test material adsorbing to walls of test apparatus		None
Experimental conditions	Temperature (ºC)	24 ± 2 °C
	Continuous darkness (Yes/No)	Yes
Other details		None

2. Sampling:

Sampling intervals	Kinetics interval, pH, redox, and dissolved oxygen	0, 7, 14, 21, 29, 43, 70 (71 for NC), and 102 days post-application
	Sterility Checks	None
Sampling method	Water Sediment	Aqueous Phase: Water decanted through filter paper. Ambient Shake: Sediment shaken at ambient temperature 3X with ACN:water (70:30 v:v), 1X ACN, centrifuged, supernatant filtered and combined. Microwave extraction: Sediment extracted 1X with ACN:water (70:30 v: v) and 1X methanol:water (70:30 v:v)
Method of collection of CO2 and volatile organics		Test systems flushed with nitrogen through volatile traps containing 2 N KOH, ethylene glycol, and 1 M H2SO4
Sample storage before analysis		Stored in freezer below -15 ºC. (LIMS ID: BLDG2WF)
Other observations, if any		None

3. Description of analytical procedures:

At each sampling interval the water and sediment were separated by decantation. The sediment was extracted sequentially three times with 30-minute ambient shakes using 50 mL 70:30 (v/v) ACN:water and one 30-minute shake with 50 mL ACN. The sediment/solvent mixture was centrifuged after each

shake extraction, and the supernatants of all ambient extracts were filtered into the same graduated cylinder. The sediment then underwent two aggressive extractions using a microwave extractor at 70 ºC for 10 minutes with first 70:30 ACN: water and one more microwave extract with 70:30 methanol/water was added after Day 14. The two aggressive extracts were combined.

Appropriate volumes of both the ambient and aggressive extracts were concentrated and analyzed by HPLC coupled to a ^{14}C detector to characterize ^{14}C-BYI 02960 residues. Water was analysed by radio-HPLC directly without concentration. Identification of the BYI 02960 was achieved by co-chromatography and liquid chromatography-electrospray ionization mass spectrometry (LC-ESI/MS). Identification of metabolites was confirmed by mass spectrometry at day 102.

The LOD was determined empirically to be the lowest concentration resulting in a peak height of approximately 3 times the background level in the chromatogram was approximately 500 dpm. T Assuming 500 dpm as the detection limit, the calculated limit of detection for the radioactivity detector would be 500 dpm/specific activity (dpm/µg) = 0.002 µg.

Triplicate 1-mL aliquots of the aqueous and the sediment extracts of the sample were radioassayed by LSC. The extracted sediment samples (soil cakes) were air dried, weighed and homogenized thoroughly with coffee grinder. Triplicate aliquots of the sediment were analyzed by combustion.

Determination of Degradation Kinetics

Dissipation rates from the water phase and rates of degradation for the total system were calculated by use of the software KinGui, version 1.1, which was built within the frame-work of MATLAB (Ver.7.0.4). The kinetic evaluation included the fitting of data with kinetic models. The bi-phasic model DFOP was chosen.

Results

Findings

The redox potential and dissolved oxygen content of the test systems indicated an anaerobic and reducing environment throughout the study (Table B.8.4.3.2-05).

Table B.8.4.3.2-05 Dissolved oxygen, pH, Eh and temperature measurements taken throughout the study period (average of replicates)

[a]: individual minor degradates did not exceed a mean of 0.7 %

Mass balance

The material balances per sampling interval for the test systems of Lawrence, KS ranged from 95.5 to 108% of the applied radioactivity, with an overall mean material balance of 99.1 ± 3.9%. The material balances per sampling interval for the test systems of Pikeville, NC ranged from 95.4 to 99.9% of the applied radioactivity, with an overall mean material balance of 98.5 ± 1.3%.

Residues in water, bound and extractable residues in sediment

In the Lawrence system the radioactive residues in the water phase decreased from an average of 99.1% at Day 0 to 48.6% at Day 7 and declined to 25.1% at the end of the study (Day 102). The radioactive residues in the sediment increased from an average of 8.8% on Day 0 to 46.8% at Day 7 and increased to 70.4 at Day 43 and 68.9% at the end of the study. Unextractable residues increased from 0.2% at Day 0 to 4.9% at the end of the study. Volatile compounds remained low with $^{14}CO_2$ ≤0.1% and organic volatiles below the LOQ. BYI 02960 decreased from 103% at Day 0 to 91.6% at the end of the study in the total Lawrence water/sediment system. No major degradates were formed in the test systems with Lawrence sediment; total minor unidentified ranged from 1.3 to 5.3% throughout the study.

In the Kansas system radioactive residues in the water phase decreased from an average of 87.3% at Day 0 to 48.4% at Day 7 and declined to 18.5% at the end of the study (Day 102). The radioactive residues in the sediment increased from an average of 11.4% on Day 0 to 49.2% at Day 7 and increased to 78.7% at Day 71 and 64.8% at the end of the study. Unextractable residues increased from 0% at Day 0 to 12% at the end of the study. Volatile compounds remained low with $^{14}CO_2$ ≤0.1% and organic volatiles below the LOQ. BYI 02960 decreased from 97.9% at Day 0 to 83.3% at the end of the study in the total water/sediment system. No major degradates were formed; the total minor unidentified ranged from 0 to 0.7% throughout the study.

Volatilization

No volatile compounds were detected in the study.

Transformation of parent compound

BYI 02960 dissipates to the sediment from aqueous phase with a half-life of 7.2 and 9.6 days for Lawrence and Pikeville, respectively. BYI 02960 is stable in the sediment under anaerobic condition with a half-life 415 days for Pikeville and greater than 1000 days for Lawrence sediment.

Table B.8.4.3.2-08 Kinetic analysis

Sediment Origination	Test System	Double First Order Parallel				DT_{90} (days)
		DT_{50} (days)	k_1 day^{-1}	k_2 day^{-1}	χ2 %	
Lawrence, KS	Water	7.2	0.1672	2.0E-4	6.0403	>1000
	Total	>1000	2.3E-14	3.5E-4	4.1304	>1000
Pikeville, NC	Water	9.6	0.0947	2.6E-14	9.0418	>1000
	Total	415	0.0026	0.0017	0.6588	>1000

Conclusions

BYI 02960 dissipated from aqueous phase to sediment with a half-life of 7.2 and 9.6 days for Lawrence and Pikeville test system, respectively. With respect to the entire test system, BYI 02960 is regarded stable under anaerobic condition, no major metabolite were formed.

Remarks

The study is acceptable. It is noted that the two systems bothe are in the low range of organic carbon content as prescribed in the OECD guideline. The water/sediment system was tested under anaerobic conditions, however the redox potential and dissolved oxygen meseaurements show that the system is not completely anaerobic. The RMS agrees with the applicant that BYI 02960 stable under anaerobic conditions. Results of this anaerobic study are not used for further assessment in the aquatic environment. The study is accepted as supplementary information.

Summary

The aerobic transformation of [pyridine-2,6-^{14}C] BYI 02960 was studied in two different water/sediment systems (Hönniger and Angler Weiher) for a maximum of 119 days in the dark at 20 ± 1 °C. In a supplementary test, the degradation of [PYR-^{14}C] BYI 02960 was studied in samples which were sterilized by gamma radiation and (separate vessels) by steam pressure. The test systems consisted of laboratory microcosm flasks attached to traps for collection of CO_2 and volatile organic compounds. Individual flasks filled a volume ratio of water to sediment of 3:1 were treated with [PYR-^{14}C] BYI 02960 with an application rate of 20.9 µg/batch corresponding to approx. 40 µg/L water assuming a maximum field application rate of 400 g BYI 02960/ha. During incubation the supernatant water was agitated gently.

Duplicate test systems were processed and analyzed after 0, 3, 7, 14, 28, 63, 91, and 119 days of incubation. The water samples were analyzed for radioactivity after centrifugation. Prior to radio-HPLC analysis, a concentration step was performed. The sediment samples were extracted at ambient temperature three times with acetonitrile/water (70/30, v/v), followed by one extraction step with pure acetonitrile. Afterwards, the sediment was extracted once more using a microwave-accelerated solvent extraction (aggressive organic extract) with 80 mL acetonitrile/water (70/30, v/v). The combined extracts from the ambient extractions and the aggressive extraction were analyzed by LSC and, after a concentration step, via radio-HPLC. Identification of BYI 02960 residues was by HPLC-MS, HPLC-MS/MS, NMR and HPLC co-chromatography.

The non-extractable residues (NER) in sediment samples were determined, and those from Hönniger Weiher in case of the last sampling date were separated into humin, humic acid and fulvic acid fractions.

The test conditions outlined in the study protocol were maintained throughout the study, and the material balance in the two test series was complete (on average 98.9% for HW and 98.0% for AW test system). The complete material balance demonstrates that no significant portion of radioactivity dissipated from the vessels or was lost during processing.

The radioactivity in the water phase of HW test systems decreased to 12.9% of AR, and in the water phase of AW test systems to 24.6% of AR at study termination. Extractable ^{14}C sediment residues in test systems from HW increased from 1.9% of the applied radioactivity at DAT-0 to 59.8% at DAT-63 and declined to 53.0% towards the end of the study. Extractable ^{14}C residues in the sediments from AW increased from 1.1% of the applied radioactivity at day 0 to 49.7% at study termination. The maximum amount of non-extractable ^{14}C residues (NER) in the sediment was 25.0% of AR for test

systems from HW and 13.6% of AR for AW (DAT-119). The fractionation of NER of HW resulted in portions of 4.5 and 5.4% of AR within the humic acids, whereas similar amounts of radioactivity were associated with the fulvic acids (9.1 and 9.3% of AR) or strongly integrated into the insoluble humin of the soil matrix (10.7 and 9.8% of AR). At the end of the study, 6.8% and 8.5% of AR were present as $^{14}CO_2$ in the test systems from HW and AW, respectively. Organic volatile compounds were not detected in significant amounts (< 0.1% of AR in all test systems).

In the water phase of HW and AW, the amount of [PYR-^{14}C] BYI 02960 decreased from 96.7 and 96.5% of AR at day 0 to 11.4 and 22.3% at study termination, respectively. In the sediment phase of HW, the amounts of BYI 02960 increased from 1.8% of AR at day 0 to a maximum of 59.4% at DAT-63, followed by a decrease to 52.6% towards the end of the study. In the AW sediment the amounts of BYI 02960 increased from 1.0% of AR at day 0 to 49.5% at study termination. Not any major transformation products were to be detected in the water phase and the sediment of both test systems. The dissipation of BYI 02960 from the water phases was mainly characterized by rapid partitioning into the sediment. The best-fit kinetic models for the determination of trigger values were the FOMC kinetic model for HW and the DFOP kinetic model for AW with DT_{50} values of 8.5 and 34.5 days, respectively. The corresponding modelling endpoints were calculated using the DFOP kinetic model. The DT_{50} values for the slow degradation phase were 63.0 and 63.6 days for the water phase of HW and AW, respectively. In the entire water/sediment systems, BYI 02960 was degraded slowly which was best described using single first-order kinetics (SFO). The estimated DT_{50} values were 193.1 and 246.9 days for test systems from HW and AW, respectively.

In the supplemental test, i.e. the test systems sterilized by gamma radiation or steam pressure and then incubated for 0, 60 or 120 days, no CO_2 was formed (≤ 0.1% AR). The amount of radioactivity in the water phase, predominantly represented by parent compound, was about two times higher than in that from the microbial active samples. Further, there was a clear trend that NER formation in sediment was lower than in the microbial active test flasks, especially seen for both test systems HW and AW sterilized by steam pressure. This shows that the NER were at least partly formed by microbial processes.

Materials and Methods

Materials

1. Test Item: BYI 02960, CAS No: 951659-40-8

[Pyridine-2,6-^{14}C] BYI 02960, sample ID: KML 9090; Specific activity = 4.49 MBq/mg (121.35 µCi/mg); Radiochemical purity: >99% (acc. Radio-HPLC and –TLC;Chemical purity: >99% (HPLC, UV detection at 210 nm)

2. Test System: The study was carried out using the natural water/sediment systems Hoenniger Weiher (HW), near Wipperfürth, Germany and Anglerweiher (AW), Leverkusen, Germany.

Hoenniger Weiher is an artificially dammed pond in the course of the Hoenniger Creek. Due to its inlet and outlet the pond (about 1000 m² in surface area) has strong water current. Anglerweiher is a reclaimed gravel pit, which is used for fishing only. The chosen systems are well characterized, physical-chemical characteristics of the water/sediment systems are summarized in Table B.8.4.3.2-08.

Water and sediment samples were taken separately and poured into plastic containers. The collected sediments were sieved down to 2 mm mesh-size to remove parts of e.g. plants and stones. The collected water phases were filtered through a 0.06 mm sieve.

Materials

1. Experimental conditions: The test systems consisted of laboratory microcosm flasks attached to traps for collection of CO_2 and volatile organic compounds. The individual static test systems were kept

at aerobic conditions at 20 ± 2 °C for a maximum period of 120 experimental days. Each vessel was filled with 175 mL of wet sediment (i.e. 118.3 and 247.9 g dry weight sediment for HW and AW) and about 525 mL of water, equivalent to approx. 6 cm in height, resulting in a volume ratio of water to sediment of 3:1. After pre-equilibration, aliquots of the application solution were directly applied onto the water surface of each system. Thereafter, the systems were closed with the trap attachment for absorbing volatile compounds from DAT 1 onwards. During incubation the supernatant water was agitated gently.

The amount of radiolabelled BYI 02960 for the treatment of the individual test systems was based on a single field use rate of 400 g/ha, calculated to a water depth of 100 cm, which resulted in a nominal application rate was 20.8 µg/batch. The actual application rate set as 100 % of applied radioactivity (100 % AR) corresponding to 1887.68 Bq/500 µL, 1885.15 Bq/500 µL and 1871.07 Bq/500 µL in the regular water/sediment systems. The material balance for the regular test systems was based on the average amount of radioactivity (RA) recovered from these measurements: 94065 Bq or 20.9 µg of test item per vessel.

2. Sampling: Duplicate samples were taken on DAT 0, 3, 7, 14, 28, 63, 91, and 119 days after application for both test systems. The water was decanted and centrifuged. The sediment was extracted with 3 x 80 mL acetonitrile/water (70/30, v/v), followed by one extraction with 80 mL acetonitrile (combination: ambient extracts). Finally, the sediment was extracted once with 80 mL acetonitrile/water (70/30, v/v) by microwave-accelerated solvent extraction (aggressive extract). Volatile organics and $^{14}CO_2$ were trapped with solid trapping attachments containing soda lime for absorption of $^{14}CO_2$ and polyurethane foam for volatile organic compounds.

3. Description of analytical procedures: The radioactivity of the supernatant and sediment samples was radio-assayed by LSC and HPLC. Volatiles were analysed by LSC. For HPLC analysis of the water phase, 10 mL of the water phase were concentrated to about 1 mL. For representative sampling dates (DAT 0, 14, 28, 63, 91 and 119), aliquots of 200 µL of the water phases were investigated by TLC without a concentration step (confirmation method).

Sediment samples were exhaustively extracted once with 80 mL acetonitrile/water (70/30, v/v) by microwave-accelerated solvent extraction for 10 minutes (temperature approx. 70°C) with magnetic stirring. After extraction and centrifugation (approx. 15 min, 2500 x *g*) the supernatant was decanted (aggressive organic extracts) and analysed with LSC. Prior to HPLC-analysis, aliquots of 10.0 mL from the ambient organic extracts and aliquots of 4 mL from the aggressive organic extracts were concentrated to volumes of about 1 mL. 200 µL aliquots of representative ambient and aggressive organic extracts (taken on DAT-0, 14, 28, 63, 91 and 119) were investigated by TLC as a confirmatory method.

Determination of Degradation Kinetics

Dissipation rates from the water phase and rates of degradation for the total system were calculated by use of the software KinGui, version 1.1. The kinetic evaluation included the fitting of data with kinetic models SFO, FOMC and DFOP to the experimental data and their assessment according to FOCUS guidance to result in values for comparison with trigger endpoints.

Results

Findings

The test conditions outlined in the study protocol were maintained throughout the study. Oxygen Saturation, pH and Redox Potential Measurements of the Aerobic Test Systems throughout the Study Period.

Data

A summary of key data on total recovery and the distribution of radioactivity into the various components formed in water and sediment is given for system Hönniger Weiher in Table B.8.4.3.2-11 and in Table B.8.4.3.2-12 for system Angler Weiher.

Mass Balance

During the study, the total recovery of radioactivity in individual test vessels ranged from 96.5 to 100.6% (mean 98.9%, RSD 1.2 %) for Hönniger Weiher and from 95.7 to 100.8% (mean 98.0%,

RSD 1.6%) for Angler Weiher. Complete material balances found for all sampling dates demonstrating that no significant portion of radioactivity dissipated from the vessels or was lost during processing.

Table B.8.4.3.2- 11 Biotransformation of [PYR-^{14}C] BYI 02960 in Hönniger Weiher under aerobic conditions, expressed as percent of AR, mean ± SD

Volatilization

Formation of $^{14}CO_2$, mineralization of [PYR-^{14}C] BYI 02960, was observed in both water/sediment test systems. At termination of the study, the $^{14}CO_2$ recovery (mean values of duplicates) in test system from HW was 6.8% of AR. In AW test system, $^{14}CO_2$ accounted for 8.5% of AR at study termination. Most of the $^{14}CO_2$ was collected in the soda lime fraction of the trap attachments, ≤ 0.3% of AR in Hönniger Weiher and ≤ 1.5% of AR in Angler Weiher was dissolved CO_2 in water. No significant amounts of organic volatiles were found (< 0.1% of AR).

Residues in water, bound and extractable residues in sediment

The radioactivity in the water phase of HW test system decreased steadily from 97.0% at day 0 to 12.9% of AR at study termination. The extractable ^{14}C residues in sediment increased from 1.9% at DAT 0 to 59.8% of AR at DAT 63 and declined to 53.0% of AR towards the end of the study. NER was 0.4% of AR at day 0 which increased to 25.0% of AR at study termination.

The radioactivity in the water phase of AW test system decreased from 97.1% at day 0 to 24.6% of AR towards the end of the study. Extractable ^{14}C residues in the sediment increased from 1.1% at day 0 to 49.7% of AR at study termination. The amount of bound residues was <0.1% of the applied radioactivity at day 0 and increased to 13.6% towards the end of the incubation period.

The NER of extracted sediments of DAT 119 from HW (both replicates) was found to be of heterogeneous nature. Portions of 4.5 and 5.4% of AR were fractionated together with the humic acids, whereas similar amounts of radioactivity were associated with the fulvic acids (9.1 and 9.3% of AR) or strongly integrated into the insoluble humin of the sediment matrix (10.7 and 9.8% of AR).

Transformation of Parent Compound

The percentages of BYI 02960 and its residues determined in water and sediment extracts are presented in Table B.8.4.3.2-11 for the system HW, and in Table B.8.4.3.2-12 for the system AW. The elimination of BYI 02960 from the water body occurred mainly via partition into the sediment phase and partly via degradation. In the sediment phase of HW, the amounts of BYI 02960 increased from 1.8% at day 0 to a maximum of 59.4% of AR at DAT-63, followed by a decrease to 52.6% of AR towards the end of the study. In the AW sediment the amounts of BYI 02960 increased from 1.0% at day 0 to 49.5% of AR at study termination.

Three very minor transformation products were observed in the water phase. One of those was detected in the water phase of both test systems, and accounted for up to 1.4 and 0.8% of AR, respectively. The others were either detected in the water phase from HW (≤ 0.8% of AR) or Angler Weiher (≤ 1.3% of AR). The maximum amount of the non-characterized radioactivity in the water phase was 0.5% of AR. No transformation products were detected in the sediment extracts from HW and AW. The maximum amount of the non-characterized radioactivity was 0.4% of AR.

Dissipation and Degradation Kinetics

After fitting of data to the three kinetic models SFO, FOMC (Gustafson-Holden) and DFOP the quality of fits was assessed according to FOCUS kinetic guidance. For the dissipation from water the best-fit kinetic models for the determination of trigger values were the FOMC kinetic model for HW and the DFOP kinetic model for AW with DT_{50} values of 8.5 and 34.5 days, respectively (Table B.8.4.3.2-13). The corresponding modelling endpoints were calculated using the DFOP kinetic model. The DT_{50} values for the slow degradation phase were 63.0 and 63.6 days for the water phases of Hönniger Weiher and Angler Weiher, respectively.

In the entire water/sediment systems, [PYR] BYI 02960 was degraded more slowly and the best fit kinetics was single first-order kinetics (SFO). The DT_{50} values were 193.1 and 246.9 days for systems from Hönniger Weiher and Angler Weiher, respectively. These values were used as trigger values and modelling endpoints (Table B.8.4.3.2-14).

Table B.8.4.3.2-13 Summary of dissipation kinetics of BYI 02960 from the supernatant water

Water Phase of Test System	Kinetic Model	DT_{50} [days]	DT_{90} [days]	Chi2 Error [%]

	FOMC	360.3	> 1000	1.2
	DFOP	> 1000	> 1000	1.3

Bold: best fit, SFO = Single First Order Model, FOMC = First Order Multi Compartment Model, DFOP = Double First Order in Parallel Model

In the supplemental test, i.e. the test systems sterilized by gamma radiation or steam pressure and then incubated for 0, 60 or 120 days, no $^{14}CO_2$ was formed (≤ 0.1% AR). The amount of radioactivity in the water phase, predominantly represented by parent compound, was about two times higher than in that from the microbial active samples. Further, there was a clear trend that NER formation in sediment was lower than in the microbial active test flasks. This shows that the NER were at least partly formed by microbial processes.

Conclusions

[PYR] BYI 02960 is microbially degraded in aerobic water/sediment systems. The DT_{50} values for BYI 02960 in the entire water/sediment systems were 193 and 247 days for Hönniger Weiher and Angler Weiher, respectively. The only major transformation products were carbon dioxide and formation of NER.

Table B.8.4.3.2-15 Results Synopsis

Parameter	Hönniger Weiher	Angler Weiher
Material Balance [% AR]	96.5 – 100.6	95.7 – 100.8
Water Phase [% AR]	12.9 – 97.0	24.6 – 97.1
Sediment Extract [% AR]	1.9 – 59.8	1.1 – 49.7
Major transformation products *	CO_2 (max. 6.8%) NER (max. 25.0%)	CO_2 (max. 8.5%) NER (max. 13.6%)

* Criteria for "major": ->10% of AR at any DAT; >5% of AR at two successive DATs, increasing towards study end

SFO = Single First-Order Model, FOMC = First Order Multi Compartment Model, DFOP = Double First Order in Parallel Model
* DT_{50} value of the slow degradation phase

Remarks

The RMS finds the water/sediment study acceptable. The modelling endpoints for water phase are not used for exposure modelling since they are not level PII true degradation values. Level PI whole system values are considered acceptable for use in environmental exposure modelling.

Summary

The aerobic transformation of [FUR-^{14}C] and [ETH-^{14}C] BYI 02960 was studied in two water/sediment systems, Hönniger Weiher (HW) and Angler Weiher (AW) for a maximum of 120 days in the dark at 20 ± 2°C. The test systems consisted of laboratory microcosm flasks attached to traps for collection of CO_2 and volatile organic compounds. Individual flasks filled a volume ratio of water to sediment of 3:1 were treated with [^{14}C] BYI 02960. The actual application rates were 20.86 and 20.80 µg/batch for label FUR and label ETH test systems from Hönniger Weiher and 20.63 and 20.53 µg/batch for label FUR and label ETH test systems from Angler Weiher, corresponding to approx. 40 µg/L water assuming a field application rate of 400 g BYI 02960/ha. During incubation the supernatant water was agitated gently.

Duplicate test systems were processed and analyzed after 0, 1, 3, 7, 14, 30, 45/44, 60/58, 87/86 and 120 days of incubation for test systems from HW and AW (both labels), respectively. The water samples were decanted and analyzed for radioactivity after centrifugation and filtration. Prior to HPLC analysis, a concentration step was performed. The sediment samples were extracted three times with

acetonitrile/water (70/30, v/v), followed by one extraction step with pure acetonitrile, all at ambient temperature (ambient organic extracts). Afterwards, the sediment was extracted once more using a microwave-accelerated solvent extraction (aggressive organic extract) with 80 mL acetonitrile/water (70/30, v/v). The combined extracts from the ambient extractions and the aggressive extract were analyzed by LSC and via HPLC after a concentration step. For selected samples, the HPLC analysis was confirmed by TLC. Identification of the two test items was achieved by HPLC-MS, HPLC-MS/MS, NMR and/or Co-chromatography. The major metabolite detected in label ETH test systems was characterized by HPLC-MS. The non-extractable residues (NER) in sediment samples were determined, and those from the last sampling date were separated into humin, humic acid and fulvic acid fractions.

The test conditions outlined in the study protocol were maintained throughout the study, and the mean material balances in all four test series ranged from 98.2 – 100.4% of AR. The complete material balance demonstrates that no significant portion of radioactivity dissipated from the vessels or was lost during processing.

The radioactivity in FUR and ETH test systems from HW water decreased steadily from 96.0 and 97.2% of AR at day 0 to 14.3 and 14.2% at study termination. The radioactivity in FUR and ETH test systems from AW water decreased from 97.9 and 98.3% of AR at day 0 to 37.3 and 44.1% towards the end of the study. Extractable ^{14}C sediment residues in FUR and ETH test systems from HW increased from 4.2 and 3.8% of AR at day 0 to 54.7 and 54.1% at study termination, respectively. Extractable ^{14}C residues in FUR and ETH sediments from AW increased from 2.2 and 2.4% of AR at day 0 to maxima of 37.7 and 40.1% of AR at study termination. The maxima of non-extractable ^{14}C residues (mean values of duplicates) in the sediments were 22.6 and 26.6% of AR for FUR and ETH test systems from HW, and 17.9 and 15.2% of AR for FUR and ETH test systems from AW, respectively.

At the end of the study period, 3.9 and 1.5% of AR were present as $^{14}CO_2$ in systems from HW, and 5.5 and 0.9% of AR were present as $^{14}CO_2$ in systems from AW, each for FUR and ETH label, respectively. The total amount mainly accounted for of $^{14}CO_2$ trapped in soda lime, but as well for the amount of $^{14}CO_2$ present in the water phase (all sampling intervals) and sediments (only DAT-120). Organic volatile compounds amounted to ≤ 0.2% of the applied radioactivity in both systems and for both labels.

In the water phase from HW, BYI 02960 decreased from 95.5 and 96.8% of AR at day 0 to 14.3 and 14.1% at study termination for FUR and ETH test systems, respectively. In AW water of FUR and ETH test systems, BYI 02960 decreased from 97.4 and 97.9% of AR at day 0 to 35.6 and 36.8% at study termination. In the sediment phase of FUR and ETH test systems from HW, BYI 02960 increased from 4.1 and 3.7% of AR at day 0 to maximum amounts of 58.7 and 58.3% at DAT-60 or DAT-45, and then slightly declined to 54.3 and 52.6% towards study termination, respectively. In AW sediment (FUR and

ETH, respectively) BYI 02960 increased from 2.2 and 2.3% of AR at day 0 to 37.6 and 38.9% at study termination.

DFA (difluoroacetic acid) was observed as a degradation product of [ETH] BYI 02960 in the water phases and in the sediment extracts of both water/sediment systems. In the water phases it accounted for up to 1.1% (HW) and 6.0% (AW) of AR, in the sediment extracts, DFA accounted for only 0.8% and 0.9% of AR, respectively. Two very minor metabolites were detected in the water phases of ETH test systems (≤ 1.1% of AR), and three very minor metabolites were detected in the water phases of FUR test systems (≤ 1.0% of AR). In the sediments, one very minor metabolite was detected in the ETH test systems (≤ 0.5% of AR) and the FUR test systems (≤ 0.1% of AR). The maximum amount of the non-characterized radioactivity was 0.5% of AR for all test systems and compartments.

The dissipation of BYI 02960 from the water phase was mainly characterized by a fast translocation into the sediment. The best-fit kinetic model for the determination of trigger values was the DFOP kinetic model with DT_{50} values of 9.8 and 9.4 days for FUR and ETH test systems from HW, and DT_{50} values of 59.2 and 66.2 days for FUR and ETH test systems from AW. The corresponding modelling endpoints were also calculated using the DFOP kinetic model. The DT50 values for the slow degradation phase were 48.5 and 50.2 days for the water phase of HW, but 123.8 and 117.5 days for the water phase of AW.

In the entire water/sediment systems, BYI 02960 was degraded slowly, the degradation was best described using single first-order kinetics (SFO). The estimated DT_{50} values were 208.2 and 202.4 days for FUR and ETH systems from HW, and 246.1 and 285.0 for FUR and ETH test systems from AW. These values are to be used as trigger values and modelling endpoints.

Materials and Methods

Materials

1. Test Items:

[Furanone-4-^{14}C] BYI 02960, sample ID: KATH 6352; Specific activity = 3.94 MBq/mg (106.46 µCi/mg); Radiochemical purity: >99% (acc. Radio-HPLC and –TLC); Chemical purity: >99% (HPLC, UV detection at 210 nm)

[Ethyl-1-^{14}C] BYI 02960, sample ID: KATH 6358; Specific activity = 3.93 MBq/mg (106.28 µCi/mg); Radiochemical purity: >98% (acc. Radio-HPLC and –TLC); Chemical purity: >98% (HPLC, UV detection at 210 nm)

2. Test System: The study was carried out using the natural water/sediment systems Hoenniger Weiher (HW, near Wipperfürth, Germany;) and Anglerweiher (AW, Leverkusen).

Hoenniger Weiher is an artificially dammed pond in the course of the Hoenniger Creek forming Hoenniger Weiher. Due to its inlet and outlet the pond (about 1000 m² in surface area) has strong water current. Anglerweiher is a reclaimed gravel pit, which is used for fishing only.. The chosen systems are well characterized.

Physical-chemical characteristics of the water/sediment systems are summarized in Table B.8.4.3.2-16.

Water and sediment samples were taken separately and poured into plastic containers. The collected sediments were sieved down to 2 mm mesh-size to remove parts of e.g. plants and stones. The collected water phases were filtered through a 0.06 mm sieve.

Materials

1. Experimental conditions: The test systems consisted of laboratory microcosm flasks attached to traps for collection of CO_2 and volatile organic compounds. The individual static test systems were kept at aerobic conditions at 20 ± 1 °C for a maximum period of 120 days. Entire vessels filled with either 82.2 g (HW) or 279.7 g (AW) dry weight sediment and 525 mL of supernatant water (volume ratio of water to sediment: 3:1) were applied with [FUR-^{14}C] or [ETH-^{14}C] BYI 02960, resulting in four parallel

test series. After pre-equilibration, aliquots of the application solution were directly applied onto the water surface of each microcosm system. Thereafter, the systems were closed with the trap attachment for absorbing volatile compounds from DAT 1 onwards. During incubation the supernatant water was agitated gently.

The nominal application rate of 20.8 µg/batch corresponds to about 40 µg/L water and was selected based on a field application rate of 400 g/ha. The actual application rates were 20.86 and 20.80 µg/flask for FUR and ETH test systems from Hönniger Weiher and 20.63 and 20.53 µg/flask for FUR and ETH test systems from Angler Weiher.

2. Sampling: Duplicate flasks were processed and analyzed after 0, 1, 3, 7, 14, 30, 45/44, 60/58, 87/86 and 120 days of incubation for test systems from HW and AW, respectively. The water phase was decanted and analyzed for radioactivity after centrifugation and filtration. Prior to HPLC analysis, a concentration step was performed. The sediment was extracted three times with acetonitrile/water (70/30, v/v), followed by one extraction step with pure acetonitrile, all at ambient temperature (ambient organic extracts). Afterwards, the sediment was extracted once more using a microwave-accelerated solvent extraction (aggressive organic extract) with 80 mL acetonitrile/water (70/30, v/v). The extracted sediment phase was freeze-dried, homogenized and combusted in an oxidizer. The evolved CO_2 was trapped in a scintillation cocktail and measured by LSC to determine the non-extractable residues.

3. Description of analytical procedures: The radioactivity of the supernatant and sediment samples was radio-assayed by LSC and HPLC. The combined extracts from the ambient extractions and the aggressive extract were analyzed by LSC and via HPLC after a concentration step. For selected samples, the HPLC analysis was confirmed by TLC. Identification of the two test items was achieved by HPLC-MS, HPLC-MS/MS, NMR and/or Co-chromatography. The major metabolite detected in the ETH test systems was characterized by HPLC-MS. Volatile organics and $^{14}CO_2$ were trapped with solid trapping attachments containing soda lime for absorption of $^{14}CO_2$ and polyurethane foam for volatile organic compounds. The non-extractable residues were separated into humin, humic acid and fulvic acid fractions for the last sampling interval.

Determination of Degradation Kinetics

Dissipation rates from the water phase and rates of degradation for the total system were calculated by use of the software KinGui, version 1.1. The kinetics evaluation included the fitting of data with kinetic models SFO, FOMC and DFOP to the experimental data and their assessment according to FOCUS guidance to result in values for comparison with trigger endpoints.

Results

The test conditions outlined in the study protocol were maintained throughout the study

* $E_h = E_{obs}$ + 210 mV [reference potential of SenTix ORP electrode (WTW) vs. standard hydrogen electrode at 20°C; manufacturer information]

without pre-incubation

Data

A summary of key data on total recovery and the distribution of radioactivity into the various components formed in water and sediment is given in Table B.8.4.3.2-19 and Table B.8.4.3.2-20 for

test system Hönniger Weiher and in Table B.8.4.3.2-21 and Table B.8.4.3.2-22 for test system Angler Weiher.

Mass Balance

During the study, the total recovery of radioactivity in individual test vessels of the HW test systems ranged from 94.9 to 100.7% (mean 98.2%, RSD 2.0%) for FUR and from 96.5 to 101.4% (mean 98.7%, RSD 1.4%) for ETH. The radioactivity in individual test vessels of the AW test systems ranged from 98.4 to 101.8% (mean 100.4%, RSD 1.1%) for FUR and from 99.4 to 101.2% (mean 100.3%, RSD 0.5%) for ETH. The complete material balance found for all sampling intervals demonstrates that no significant portion of radioactivity dissipated from the vessels or was lost during processing.

Table B.8.4.3.2-19 Biotransformation of [FUR-^{14}C] BYI 02960 in Hönniger Weiher under aerobic conditions, expressed as percent of AR, mean ± SD

Volatilization

Formation of $^{14}CO_2$, i.e. mineralization of BYI 02960, was observed in all water/sediment systems. At termination of the study, the $^{14}CO_2$ recovery (mean values of duplicates) in systems from HW was 3.9 and 1.5% of AR for FUR and ETH, respectively. In AW water/sediment systems, $^{14}CO_2$ accounted for 5.5 and 0.9% of AR at study termination for FUR and ETH, respectively. Organic volatiles were < 0.2% of the applied radioactivity for both systems and labels.

Residues in water, bound and extractable residues in sediment

The radioactivity in FUR and ETH test systems from Hönniger Weiher water decreased steadily from 96.0 and 97.2% of AR at day 0 to 14.3 and 14.2% of AR at study termination. The radioactivity in FUR and ETH test systems from Angler Weiher water decreased from 97.9 and 98.3% of AR at day 0 to 37.3 and 44.1% of AR towards the end of the study. The elimination of BYI 02960 from the water body occurred mainly via translocation into the sediment phase and partly via degradation.

The extractable radioactivity in FUR and ETH test systems from HW increased from 4.2 and 3.8% of AR at day 0 to 54.7 and 54.1% of AR at study termination, respectively. Extractable ^{14}C residues in FUR and ETH sediment from Angler Weiher increased from 2.2 and 2.4% of AR at day 0 to maxima of 37.7 and 40.1% of AR at study termination. This indicates a rapid partitioning of BYI 02960 residues from the water phases into the sediments.

The NER for FUR and ETH test systems from HW were 0.4 and 0.3% of AR at day 0 and increased to 22.6 and 26.6% of AR at study termination, respectively. For AW water/sediment systems (FUR and ETH, respectively), the amount of NER was 0.5% of AR at day 0 and increased to 17.9 and 15.2% of AR towards the end of the incubation period. By further characterization it was found that the NER was of a heterogeneous nature in case of both types of sediments and for both radiolabels. In the sediments from HW, portions of only 1.4 and 1.8% of the NER were fractionated together with humic acids, whereas the major portion of radioactivity (53.9 and 59.0% of NER for FUR and ETH, respectively) was associated with fulvic acids. Amounts of 45.2% (FUR) and 42.9% (ETH) of the NER were found strongly integrated into the insoluble humin of the sediment matrix. In the sediment from

AW, only 4.8 and 2.4% of the NER were fractionated together with humic acids for FUR and ETH, respectively, whereas similar amounts of radioactivity were associated with fulvic acids or strongly integrated into the insoluble humin of the sediment matrix (45.4 and 47.2% of the NER for FUR; 47.9 and 49.1 for ETH).

Transformation of Parent Compound

In the water phase from HW, the amount of BYI 02960 decreased from 95.5 and 96.8% of AR at day 0 to 14.3 and 14.1% of AR at study termination for FUR and ETH test systems, respectively. In the AW water of FUR and ETH test systems, the amount of BYI 02960 decreased from 97.4 and 97.9% of AR at day 0 to 35.6 and 36.8% of AR at study termination.

One major peak was observed in the water phase of ETH test systems, accounting for up to 1.1% of AR in the water phase from HW, and 6.0% of AR in water phases from AW. The metabolite was identified as DFA using HPLC-MS. Further, two very minor metabolites were detected in the water phases of ETH test systems (≤ 1.1% of AR) and three very minor metabolites were detected in the water phases of FUR test systems (≤ 1.0% of AR). The maximum amount of the non-characterized radioactivity was 0.5% of AR for all water phases.

In the sediment phase of FUR and ETH test systems from HW, the amount of BYI 02960 increased from 4.1 and 3.7% of AR at day 0 to maximum amounts of 58.7 and 58.3% of AR at DAT-60 or DAT-45, and then slightly declined to 54.3 and 52.6% of AR towards study termination. In the AW sediment (FUR and ETH, respectively) the amount of BYI 02960 increased from 2.2 and 2.3% of AR at day 0 to 37.6 and 38.9% of AR at study termination. –DFA was also observed in the ETH sediments with maximum amounts of 0.8% of AR (DAT-87) for HW and 0.9% of AR (DAT 120) for sediment from AW. Additionally one very minor metabolite was detected in the ETH sediments (≤ 0.5% of AR) and FUR sediments (≤ 0.1% of AR), respectively. The maximum amount of the non-characterized radioactivity was 0.4% of AR for all sediments.

The BYI 02960 residues in the entire test systems from HW declined to 68.6 and 66.7% of AR at study termination, FUR and ETH, respectively. In the entire FUR and ETH test systems from AW, 73.1 and 75.7% of AR were found as unchanged test item at the end of the incubation period.

The metabolite DFA was found at maximum amounts of 1.4% (Hönniger Weiher, DAT-87) and 6.9% of AR (Angler Weiher, DAT-120). The maximum amount of a single minor radioactivity zone in both systems and with both labels was 1.1% of the AR.

Dissipation Kinetics

The dissipation of BYI 02960 from the water phase is mainly characterized by a fast translocation into the sediment which is best described using bi-phasic kinetic models. The best-fit kinetic model for the determination of trigger values was the DFOP kinetic model with DT_{50} values of 9.8 and 9.4 days for

FUR and ETH test systems from Hönniger Weiher and DT_{50} values of 59.2 and 66.2 days for FUR and ETH test systems from Angler Weiher. The corresponding modelling endpoints were also calculated using the DFOP kinetic model. The DT_{50} values for the slow degradation phase were 48.5 and 50.2 days for the water phase of Hönniger Weiher, but 123.8 and 117.5 days for the water phase of Angler Weiher which is much more of sandy type.

In the entire water/sediment systems, BYI 02960 the degradation was best described using single first-order kinetics (SFO). The estimated DT_{50} values were 208.2 and 202.4 days for FUR and ETH systems from Hönniger Weiher and 246.1 and 285.0 for FUR and ETH test systems from Angler Weiher. These values were used as trigger values and modelling endpoints.

Table B.8.4.3.2-23 Summary of dissipation kinetics of BYI 02960 from the supernatant water; evaluation for trigger values according to FOCUS

Conclusions

BYI 02960 is translocated from the water phase into the sediment where it is slowly degraded and mineralized. Major transformation products were mineralization to carbon dioxide, formation of NER and one major metabolite, DFA, (max. 6.9% of AR). An overall result synopsis is shown by Table B.8.4.3.2-27.

Table B.8.4.3.2-27 Results Synopsis

Remarks

The RMS finds the water/sediment study acceptable. The modelling endpoints for water phase are not used for exposure modelling since they are not level PII true degradation values. Level PI whole system values SFO kinetics are considered acceptable for use in modelling.

Summary

The aerobic transformation of the metabolite [1-^{14}C] DFA was studied in two water/sediment systems Hönniger Weiher (HW) and Angler Weiher (AW) for a maximum of 99 days in the dark at 19.2 ± 0.1 °C. The application rate of 4.7 µg DFA per test system was the ten-fold overdose of the application rate calculated based on the use rate of the parent compound BYI 02960 (400 g/ha) and the maximum amount of BYI 02960-DFA formed in the parent aerobic aquatic metabolism study (6.9%). The test systems consisted of laboratory microcosm flasks attached to traps for the collection of CO_2 and volatile organic compounds. Entire vessels filled with either 88.4 g (HW) or 210.3 g (AW) dry weight sediment and 520 mL of supernatant water (volume ratio of water to sediment: 3:1) were treated with [1-^{14}C] BYI 02960-DFA. During incubation the supernatant water was in smooth motion.

Samples were taken after 0, 7, 19, 33, 61, 79 and 99 days of incubation. The water layers were decanted and centrifuged. The sediment samples were extracted stepwise with acetonitrile/water mixtures at ambient temperature (ambient organic extracts). Afterwards, the sediment was extracted once more using a microwave-accelerated solvent extraction (aggressive organic extract). The extracted sediment phase was air-dried or freeze-dried, homogenized and combusted in an oxidizer in order to determine the non-extractable residues (NER). The water phases and the combined extracts of the ambient extraction steps were analyzed by LSC and TLC in order to determine the amounts of the test item and its transformation products. The aggressive extracts were only analyzed by LSC since they contained only low amounts of radioactivity. Identification of the test item in application solution was achieved by HPLC-MS, HPLC-MS/MS and NMR.

The test conditions outlined in the study protocol were maintained throughout the study. The mean material balances in the two test series ranged from 97.7 to 105.8% for test systems from Hönniger Weiher and from 97.7 to 107.6% for test systems from Angler Weiher.

The radioactivity in the water phase of HW test systems decreased steadily from 97.6% at day 0 to 34.6% of AR at study termination. The radioactivity in the water phase of AW test systems decreased from 100.0% of AR at day 0 to 80.1% at DAT-7 and varied between 75.0% (DAT-79) and 83.8% (DAT-33) afterwards. Extractable sediment ^{14}C residues in test systems from HW increased from 2.8% of at day 0 to 27.7% of AR at DAT-61 and declined to 24.1% towards the end of the study. Extractable ^{14}C residues in the sediment from AW accounted for 1.5% of at day 0 and varied between 16.2% (DAT-7) and 17.2% of AR (DAT-79) afterwards. The maximum of non-extractable ^{14}C residues (NER) in the sediment were 15.8% and 6.5% of AR for test systems HW and AW at DAT-61, respectively. The maximum of $^{14}CO_2$ in the test systems from HW and AW were 25.1% and 7.5% of AR, respectively.

The majority of total $^{14}CO_2$ accounted for volatile $^{14}CO_2$ trapped by the soda lime. A very minor portion included in those values was $^{14}CO_2$ present dissolved in the water phases (all sampling dates) and sediments (only DAT-99). Organic volatile compounds were not detected in significant amounts (< 0.1% of the applied radioactivity in all test systems).

In the water phase of HW, BYI 02960-DFA decreased from 93.8% of AR at day 0 to 32.3% at study termination. In the water of AW, BYI 02960-DFA decreased from 95.4% of AR at day 0 to 78.3% at DAT-7 and varied between 72.3% (DAT-79) and 81.1% (DAT-33) afterwards. In the sediment phase of HW, BYI 02960-DFA increased from 2.8% of AR at day 0 to a maximum of 25.2% at DAT-79 and then declined 22.7% towards the end of the study. In the sediment phase of AW, BYI 02960-DFA accounted for 1.5% of AR at day 0 and varied between 13.3% (DAT-33) and 16.5% (DAT-79) afterwards. Just minor transformation products were observed in the water and sediment phase of both test systems.
The dissipation of DFA from the supernatant water phase was characterized by translocation into the sediment and by degradation. This was best described using the DFOP kinetic model with DT_{50} values of 54.2 and 583.9 days for Hönniger Weiher and Angler Weiher, respectively. The corresponding modelling endpoints were either determined using the DFOP kinetic model (Hönniger Weiher), resulting in a DT_{50} value of 75.3 days for the slow degradation compartment, or the SFO kinetic model (Angler Weiher) with a DT_{50} value of 371.5 days. In the entire water/sediment systems, -DFA was degraded slowly which was best described using the DFOP kinetic model. The estimated DT_{50} values were 106.5 and 967.1 days for test systems from Hönniger Weiher and Angler Weiher. The corresponding modelling endpoints were determined using the SFO kinetic model with estimated DT_{50} values of 109.0 and 567.2 days for test systems from Hönniger Weiher and Angler Weiher,.

Materials and Methods

Materials

1. Test Item: DFA: CAS No: 2218-52-2 (sodium salt), 381-73-7 (free acid), [1-^{14}C] BYI 02960-DFA, sample ID: KATH 6450; Specific activity = 2.84 MBq/mg (76.68 µCi/mg); Radiochemical purity: >98% (acc. Radio-HPLC –RA); Chemical purity: >99.5% (HPLC); [1-^{14}C-] BYI 02960-DFA was identified via NMR, HPLC-MS and HPLC-MS/MS in stock solution, and via NMR and HPLC-MS with accurate mass detection in application solution

2. Test System: The water/ sediment systems were taken from Hönniger Weiher (HW), near Wipperfürth, Germany and Angler Weiher (AW), Leverkusen, Germany. Hoenniger Weiher is an artificially dammed pond in the course of the Hoenniger Creek forming Hoenniger Weiher. Due to its inlet and outlet the pond (about 1000 m² in surface area) has strong water current. Anglerweiher is a reclaimed gravel pit, which is used for fishing only. The chosen systems are well characterized. Physical-chemical characteristics of the water/sediment systems are summarized in Table B.8.4.3.2-28. Water and sediment samples were taken separately and poured into plastic containers. The

collected sediments were sieved down to 2 mm mesh-size to remove parts of e.g. plants and stones. The collected water phases were filtered through a 0.06 mm sieve.

Methods

1. Experimental conditions: The tests were performed using individual static test systems held at aerobic conditions at 19.2 ± 0.1 °C for a maximum period of 99 experimental days. Each vessel was filled with 175 mL of wet sediment and about 520 mL of water, equivalent to approx. 6 cm in height, resulting in a volume ratio of water to sediment of 3:1. After pre-equilibration, aliquots of the application solution were directly applied onto the water surface of each microcosm system. Thereafter, the systems were closed with a solid trap attachment for absorbing volatile compounds from DAT 1 onwards.

The amount of radiolabelled DFA for the treatment of the test systems was based an application rate of the parent compound (400 g/ha, calculated to a water depth of 100 cm). The actual application rate set as 100 % of applied radioactivity (100 % AR) corresponding to 266.78 Bq/500 µL (prior to application), 265.82 Bq/500 µL (during application) and 270.17 Bq/500 µL (after application) in the water/sediment

systems. The material balance was based on the average amount of radioactivity (RA) recovered from these measurements: 13380 Bq or 4.7 µg BYI 02960-DFA per test system.

2. Sampling: Duplicate samples were taken on DAT 0, 7, 19, 33, 61, 79, and 99 days after application for test systems from Hönniger Weiher and Angler Weiher. The water was decanted and centrifuged. The sediment samples were exhaustively extracted with 3 x 80 mL acetonitrile/water (50/50, v/v), followed by one extraction 80 mL acetonitrile/water (70/30, v/v) all at ambient temperature (combination: ambient extract). Afterwards, the sediment was extracted once more using a microwave-accelerated solvent extraction (aggressive organic extract) with 80 mL acetonitrile/water (70/30, v/v) for 10 minutes (temperature approx. 70°C) with magnetic stirring.

Volatile organics and $^{14}CO_2$ were trapped with solid trapping attachments containing soda lime for absorption of $^{14}CO_2$ and polyurethane foam for volatile organic compounds. The extracted sediment phase was air-dried or freeze-dried, homogenized and combusted in an oxidizer in order to determine the non-extractable residues (NER).

3. Description of analytical procedures: The water phase and combined extract of the ambient extraction steps were analyzed by LSC and TLC in order to determine the amounts of the test item and its transformation products. The aggressive extract was only analyzed by LSC since they contained only low amounts of radioactivity. The very minor transformation products detected in the water layers and sediment extracts were characterized according to their R_f-values in TLC-analysis. No identification procedures were needed or performed. Quantification of the microbial activity in the sediments was based on the method of substrate-induced initial respiratory response (SIR).

Determination of Degradation Kinetics

Dissipation rates from the water phase and rates of degradation for the total system were calculated by use of the software KinGui, version 1.1. The kinetic evaluation included the fitting of data with kinetic models SFO, FOMC and DFOP to the experimental data and their assessment according to FOCUS guidance to result in values for comparison with trigger endpoints.

Results

The test conditions outlined in the study protocol were maintained throughout the study.

* The redox potential of the buffer solution was not determined at DAT-7. Therefore, the mean value of the other measurements as used to calculate the Redox E_h Potentials at this sampling date.

Data

A summary of key data on total recovery and the distribution of radioactivity into the various components formed in water and sediment is given for system Hönniger Weiher in Table B.8.4.3.2-31 and in Table B.8.4.3.2-32 for system Angler Weiher.

Mass Balance

During the study, the total recovery of radioactivity in individual test vessels ranged from 97.7 to 105.8% of AR (mean 100.7%, RSD 2.7 %) for HW and from 97.7 to 107.6% of AR (mean 103.0%, RSD 2.9%) for AW. The complete material balance found for all sampling dates demonstrated that no significant portion of radioactivity dissipated from the vessels or was lost during processing (for detailed results see resp. tables).

Volatilization

Formation of $^{14}CO_2$ was observed in all water/sediment systems. At termination of the study, the $^{14}CO_2$ recovery (mean values of duplicates) in systems from HW was 25.1% of the applied radioactivity. In AW test system, $^{14}CO_2$ accounted for max. 7.5% of the applied radioactivity at DAT-79. From these data it can be concluded that DFA is mineralized in water/sediment systems. No significant amounts of organic volatiles were found (< 0.1% of AR).

Residues in Water, Bound and Extractable Residues in Sediment

The radioactivity in the water phase of HW test system decreased steadily from 97.6% of AR at day 0 to 34.6% at study termination. The extractable radioactivity increased from 2.8% of AR at DAT 0 to 27.7% at DAT 61 and declined to 24.1% towards the end of the study. The bound residues were 5.4% of the applied radioactivity at day 0 and slightly increased during the course of the study. The maximum amount of bound residues (15.8% of AR) was detected on DAT 61.

The radioactivity in the water phase of AW test systems decreased to 80.1% of AR at day 7 and varied between 75.0% (DAT 79) and 83.8% (DAT 33) afterwards. Extractable ^{14}C residues in the sediments accounted for 1.5% of AR at day 0 and varied between 16.2% (DAT-7) and 17.2% (DAT-79) afterwards. The amount of bound residues was 4.6% of AR at day 0. During the entire study period the amounts of bound residues varied between 1.0% (DAT 19) and 6.5% (DAT 61). Due to their low amounts (< 20%), the non-extractable residues were not further characterized.

Along with the overall metabolism of BYI 02960-DFA bound residues were formed. Their maximum amounts were comparatively low and accounted for 15.8 and 6.5% of AR for water/sediment systems from Hönniger Weiher and Angler Weiher, respectively.

Transformation of Test Item

The BYI 02960-DFA residues in the entire test systems from HW declined from 96.6% of AR at DAT 0 to 55.0% of AR at study termination. In the entire test systems from AW, the decrease of the test item was less pronounced. There, unchanged test item accounted for 89.7% of AR at the end of the incubation period. The maximum amount of a single minor radioactivity zone in the water phase of both test systems was 2.7% of AR; in the sediment it was max. 3.3% of AR.

DAT: day after treatment, SD: standard deviation, < LOD = Peak contained less than 0.22 Bq

Remark: Due to the low amounts of radioactivity present in the aggressive organic extracts, only the ambient organic extracts were subjected to TLC-analysis. The amounts of DFA and its metabolites in the sediment were calculated for the sum of ambient and aggressive organic extracts, assuming that the distribution of radioactivity in the aggressive extracts is equal to the distribution in the ambient extracts.

Dissipation Kinetics

The dissipation of BYI 02960-DFA from the supernatant water phase was characterized by translocation into the sediment and by degradation. This was best described using the DFOP kinetic model with DT_{50} values of 54.2 and 583.9 days for Hönniger Weiher and Angler Weiher, respectively (see Table B.8.4.3.2-33). The corresponding modelling endpoints were either determined using the DFOP kinetic model (Hönniger Weiher), resulting in a DT_{50} value of 75.3 days for the slow degradation compartment, or the SFO kinetic model (Angler Weiher) with a DT_{50} value of 371.5 days (see Table B.8.4.3.2-34).

In the entire water/sediment systems, BYI 02960-DFA was degraded slowly which was best described using the DFOP kinetic model. The estimated DT_{50} values were 106.5 and 967.1 days for test systems from Hönniger Weiher and Angler Weiher, respectively (see Table B.8.4.3.2-33). The corresponding modelling endpoints were determined using the SFO kinetic model with estimated DT_{50} values of 109.0

and 567.2 days for test systems from Hönniger Weiher and Angler Weiher, respectively (see Table B.8.4.3.2-34).

Table B.8.4.3.2-33 Kinetics evaluation (trigger and modelling values according to FOCUS) of the dissipation of DFA

Supernatant Water of Test System	Kinetic Model	DT_{50} [days]	DT_{90} [days]	Chi^2 Error [%]
Hönninger Weiher	SFO	63.2	210.1	6.6
	FOMC	50.7	> 1000	4.7
	DFOP	**54.2**	**229.9**	**1.6**

Conclusions

The dissipation of DFA from the supernatant water phase was characterized by translocation into the sediment and by slowly degradation. With the exception of mineralization to carbon dioxide and formation of NER no major metabolite was found. An overall result synopsis is shown by Table B.8.4.3.2-34.

Table B.8.4.3.2-34 Results Synopsis

Parameter	Hönniger Weiher	Angler Weiher
Material Balance [% AR]	97.7 – 105.8	97.7 – 107.6
Water Phase [% AR]	34.6 – 97.6	75.0 -100.0
Sediment Extract [% AR]	2.8 – 27.7	1.5 – 17.2
$^{14}CO_2$ [max. %]	25.1	7.5
Major transformation products * [max. %]	NER: 15.8	NER: 6.5
Kinetics Evaluation, Trigger Values		
Supernatant water	54.2	583.9
Entire system	106.5	967.1
Kinetics Evaluation, Modelling Endpoints		
Supernatant water	75.3#	371.5
Entire system (SFO)	109.0	567.2

* Criteria for "major": ->10% of AR; >5% of AR at two successive DAT, increasing towards study end
# DT50 value of the slow degradation phase as a worst case scenario for risk assessment

Remarks

The RMS considers the water/sediment study acceptable. Th modelling endpoints for water phase are not used for exposure modelling since they are not level PII true degradation values. Level PI whole system values are considered acceptable for use in modelling.

Summary

The fate of BYI 02960 (tech.) was determined in pond water and sediment in outdoor microcosms as an aquatic model ecosystem for lentic aquatic freshwater systems with different trophic levels. For this purpose, 4 microcosms were treated with two different concentrations of the test item. During the consecutive months samples of water and sediment were taken and the content of the test item in these compartments was analyzed. Additionally several parameters of water and sediment were monitored to characterize the system.

In November 2009 a pond with the shape of a stub pyramid (bottom 53 m^2, surface 80 m^2) was filled with a layer of natural sediment (0.15 m height) and water (0.7 m height). The walls and bottom of the pond is made of plastic foil. The sediment originated from a drinking water reservoir system, the water was composed of local ground water and water from a natural pond. Twenty-five enclosures (= microcosms) made of polycarbonate (diameter 0.97 m. height 0.9 m) were inserted into the pond on May 4, 2010 (= about 4 weeks before application). Overall, the microcosms are representative for small stagnant water bodies.

The test substance BYI 02960 (tech.) (Batch ID: 2009-000239) was applied once on June 02, 2010 onto the water surface of four microcosms. Two treatment levels, 10 and 100 µg a.i./L, were tested with two replicates each:. Two microcosms were kept untreated as controls. The microcosms were investigated for a period of 148 days after the treatment. Several times during the study period water and sediment samples were taken and analyzed to demonstrate the initial test concentrations and the fate of the test substance in these compartments. The physic-chemical water parameters were also evaluated. Furthermore the abundance of filamentous algae und the turbidity of the water was assessed.

The results of initial concentrations demonstrated that the nominal concentrations had been applied. A steady decline of BYI 02960 in the water phase was shown. At the end of the study (= 5 months after application) the a.i. concentration was 22% of applied amount at the test concentration of 10 µg a.s./L, and 40% of applied amount at 100 µg a.s./L concentration level. The analyzed concentrations of BYI 02960 in the sediment did not show a clear trend during the entire study period, although a slight

increase of BYI 02960 concentrations was observed towards the end of the study. For the 10 µg a.s./L-level, 2.3 to 7.5% of applied amount was found in the sediment; for the 100 µg a.s./L-level, 1.9 to 11.4 % of the applied amount were detected in the sediment.

The half-life calculations for BYI 02960 in the microcosm water using SFO kinetics model resulted on average (arithmetic mean) for both concentration level in 80.6 days, and in the entire system (water + sediment) in 95.1 days. A calculation for the fate in sediment was not given, since the fate of BYI 02960 in this matrix did not show a clear pattern of decline.

Materials and Methods

Materials

1. Test Item: BYI 02960 (tech.); Origin Batch No. 2009-000239; Batch code BYI 02960-01-03; Specification No. 102000022313); Analyzed a.i. content: 96.2% w/w;

Application solution: 6.34 g of test item was dissolved in 50 mL DMF, which was suspended in pure water to get nominal 10 and 100 µg a.s./L concentration level after treatment.

2. Test System: In Nov. 2009 a pond with the shape of a stub pyramid (bottom 56 m^2, surface 80 m^2) was filled with a layer of natural sediment (0.15 m height) and water (0.7 m height). The walls and bottom of the pond consist of a plastic foil. The sediment originated from “Hönniger Weiher”, part of the water reservoir system “Wuppertalsperre (Wupperverband)”, 50 km distant from the testing facility. The sediment was taken in November 2009 by means of an excavator, transported in containers to Monheim am Rhein and uniformly distributed among the pond bottom thereafter. The water was composed of local ground water and water from a natural pond.

Twenty-five cylindrical enclosures (= microcosms) made of polycarbonate (diameter 0.97 m. height 0.9 m, previous to light) were inserted into the pond on May 4, 2010 (= about 4 weeks before application). Six of these microcosms) were used for the present fate-o-cosm. To ensure conditions as close to nature as possible, the tanks are not roofed and are exposed to outdoor weather conditions. Overall, the microcosms are representative for small stagnant water bodies.

Methods

3. Experimental conditions: On day 0 an aqueous suspension of the test substance was applied using a pipette and a small glass plate. The glass plate was held onto the water surface. The application suspension was transferred onto the glass plate using a glass pipette. The application suspension did run via the glass plate into the microcosms simulating a run off scenario. The mean water height in the microcosms on day 0 was 0.66 m corresponding to 488 L water / microcosm.

Two treatment levels were tested, with two replications each: 10 and 100 µg a.i./L. Two microcosms were kept untreated as controls. The microcosms were investigated for a period of 148 days after the treatment. Several times during the study period water and sediment samples were taken and analyzed to demonstrate the initial test concentrations and the fate of the test substance in these compartments. The physic-chemical water parameters were also evaluated and reported. Furthermore the abundance of filamentous algae und the turbidity of the water was assessed.

At least once per week the oxygen content, temperature, pH and conductivity were measured in the centre of the water column. The measurements were made directly in the pond water with electronic measuring instruments. Several times during the study ammonium, nitrite, nitrate, total nitrogen, total phosphate, ortho-phosphate, carbonate hardness, sum of alkaline earth's (=total hardness) were determined. Carbonate hardness and sum of alkaline earth were measured by means of commercial tests. Ammonium, nitrite, nitrate, total nitrogen total phosphate and ortho-phosphate were determined by means of commercial photometric tests. Redox potential in water was determined monthly during the study. Total organic carbon (TOC) in water and dissolved organic carbon (DOC) in water were determined at study start and on days 84 and 148.

Parameters at day 0 were determined in non-treated sediment outside of the microcosms. At day 84 and 148 (=study end), the parameters were determined in the sediment of the control microcosms (mixed sample of both microcosms). The Redox potential was determined directly in the sediment of both control microcosms. At the start of the study, on day 84 and at the end of the study the following parameters of the sediment were determined: Total organic carbon and microbial biomass. The redox potential was measured monthly parallel to the water. This measurement was performed according to common guidelines. The characteristics of test system are summarized in Table B.8.4.3.2-35

4. Sampling: Samples were taken on 0, 1, 7, 14, 28, 56, 84, 120 and 148 days after application.
Mixed water samples out of the entire water column were taken for analysis to investigate the fate of the substance in water during the study period. For this purpose the water samples were obtained with a flask attached to a metal rod. The flask (1.0 L glass bottle) was moved around in the microcosm during filling to obtain water from different sites. 6 x 20 mL of the water samples were filled into 50 mL amber glass bottles and deep frozen at < - 18 °C until analysis.

Sediment samples were taken by means of a corer (inner diameter of 5.0 cm) at two to three sampling points each sampling time. The sample points were noted to avoid multiple sampling at one sampling point. Water covering the sediment was decanted carefully and the sampled sediment-column was filled into a glass-beaker with the same dimensions as the core. As it can be assumed that the test substance primarily adsorbed to the upper layer of the sediment, the upper 2 to 3 cm of the sediment samples were mixed for analyses (= ca. 170 g wet weight). The resulting sediment samples were frozen and stored at < -18°C until analysis. Sediment samples of the control microcosms were also taken at each time.

5. Description of analytical procedures: The water samples were analysed according to Method 01182: Method 01182 for the determination of BYI 02960 in test water from aquatic toxicity tests by HPLC-MS/MS. In the method 01182 the linearity of the detector was checked for BYI 02960 in the range 0.05 to 11 µg/L with an injection volume of 10 µL. The correlation coefficient was 0.9993.

In the present study the method was validated concurrently with the sample analyses of the study by evaluation of the standard injections. To the samples from day 84 until 148 a volume of 1 mL acetonitrile was added. Before measurement 0.1 mL formic acid was added to the samples. The water samples were directly injected into the HPLC-MS/MS instrument. The injection volume was 10 µL. Each sample was injected in duplicate. The limit of quantification (LOQ) of BYI 02960 in the pond water was 1.141 µg a.i./L.

Sediment samples of 20 g were extracted with 40 mL of acetonitrile/water (1/4; v/v) for 3 minutes in a microwave at 250 W. An aliquot of 1.5 mL was taken and centrifuged for 5 minutes at > 12000 g to remove fine particles of the sediment. The supernatant was taken and injected into the HPLC-MS/MS system. Two replicates (A + B) of 20 g each were analysed from each sample. The mean value of both replicates is reported. The sediment samples were analysed according to the following method: Analytical Method 01074 for the Determination of BYI 02960 in Soil using LC/MS/MS. Additional recovery experiments for sediment at a LOQ level of 1 µg/kg were conducted. The limit of quantification (LOQ) was 5.0 µg BYI 02960/kg dry weight of sediment.

Determination of Degradation Kinetics

The dissipation kinetics of BYI 02960 in the microcosm ponds was evaluated based on a simple first order, single compartment model. An exponential decline curve was fitted to the experimental data, and the rate constant k, as well as the characteristic dissipation times DT50 (dissipation time of 50% of the test item) was derived from this calculation. The decline curves and regression analyses for BYI 02960 were calculated with the Single First Order mathematical model (SFO). The used program was KinGUI Version 2. Model input data sets were the residual concentrations of BYI 02960 in water found in each pond at each sampling interval (displayed as % of nominal content). The total residues in each pond were calculated based on the measured residues in water plus sediment (displayed as mg a.i./microcosm). All data points were weighted equally.

Results

The analyzed concentrations of the application solutions indicated that 118 and 112% of nominal test concentration were applied into the pond water in case of the two treatment levels of 10 and 100 µg a.i./L.

Water Layer

The analyzed concentrations of the mixed samples are shown in Table B.8.4.3.2-36 and in Table B.8.4.3.2-37 as percentage of nominal application. For the calculation of percentage values the actual water volume in the microcosms at the time of sampling was taken into consideration.

Sediment

The results of the analysis of BYI 02960 in sediment are summarized in Table B.8.4.3.2-38. The samples for analysis were taken from the uppermost 2-3 cm layer. The total dry weight of this sediment layer was around 7.13 kg per microcosm. The analyzed concentrations were multiplied by this value to calculate the % of the initial applied.

Dissipation Kinetics

The dissipation of BYI 02960 from the supernatant water phase was characterized by translocation into the sediment and by degradation. The half-life calculations for BYI 02960 in the microcosm water and the total system (water + sediment) are displayed in Table B.8.4.3.2-39. A calculation for the decline in sediment was not possible, since the fate of BYI 02960 in this matrix did not show a continuous pattern.

Table B.8.4.3.2-39 SFO DT_{50}- values calculated for BYI 02960 in water and the entire test system

Nominal test concentration (µg a.i./L)	DT_{50} – Water (days)	DT_{50} – Total System (water+sediment)

		(days)
10	62.1	74.1
100	99.1	116
Arithmetic mean	**80.6**	**95.1**
Geometric mean	**78.4**	**92.7**

Conclusion

BYI 02960 dissipated from the supernatant water phase with a mean DT_{50} of 81 days due to translocation into the sediment and by degradation. The overall degradation (mean of 95 days) was faster under the prevailing outdoor conditions in comparison to the laboratory water sediment studies. Considering that BYI 02960 is rapidly degraded by photolysis there may be an enhanced degradation effect of sunlight under the outdoor test conditions.

Remarks

- The calculated half-lives for water and total system are not influenced by the use of the intended nominal concentrations instead of the presumably dosed nominal concentrations.
- The largest part of pesticide mass is expected to reside in the upper 1 or 2 cm sediment (see the results of Crum et al. (1997)) for linuron (K_{oc} of around 700 L/kg, so same order of magnitude as BYI 02960's value of around 50 L/kg) in 0.5 m deep ditches with high organic matter contents in the upper 2 cm; (see also Adriaanse et al. (2012)) for prosulfocarb (K_{oc} of around 1700 L/kg). Thus, dividing the pesticide mass by the sediment mass of a 2 cm depth results in another concentration than dividing by the sediment mass of a 3 cm depth. So, the variability is (at least partly) due to the calculation procedure and calculated concentrations (and thus also percentages) do not necessarily reflect the real penetration into sediment. It is therefore more logic to calculate the mass of BYI 02960 per unit area of sediment surface (i.e. using the cross sectional area of the core): in that way the concentration does not depend on the sampling depth. The errorneous procedure to calculate concentration and mass in the sediment has a negligible influence on the calculated half-lives, because few mass (max 11.4% of total applied) has penetrated into the sediment.
- It is unknown what the realised initial concentrations in the enclosures were because, these were not measured. Measuring the concentration in the application solution does not guarantee that the realised initial concentrations in the enclosures were equal to the intended or presumably dosed nominal concentrations. In this study the realised initial concentration might for instance be lower in case the glass plate used for applying BYI 02960 was not properly rinsed and so realised nominal concentrations might differ per enclosure. The calculation error in mass presumably dosed in the application solution results in higher initial concentrations than the ones reported. From day 1 concentrations have been measured (and so, they are assumed to reflect reality), so presumably dosed mass is not relevant anymore. By using the reported lower initial concentrations calculated dissipation half-lives are conservative.
- BYI 02960 dissipates considerably faster in the enclosure with the 10 µg a.s./L treatment level

than in the enclosure with the 100 µg a.s./L treatment level. The RMS is unable to explain this and recommends not to use an average value, but to maintain the two separate values. Next, the RMS recommends to select the half-life of the treatment level that is closest to the exposure concentration level in the exposure scenarios used in the registration procedure.

- For use in registration the DT_{50} has to be calculated back to 20°C with the Arrhenius equation. In this study the water temperature varied between 16 and 27°C during the first 3 to 4 months after application, i.e. temperatures seem somewhat higher than 20°C, so the presented half-lives may be slightly too short (i.e. not conservative).
- BYI 02960's dissipation and degradation half-life represents the half-life as a 'bulk' process, it does not yield explanatory, quantitative dissipation and degradation process descriptions. This implies that the half-lives found are system specific and cannot be generalised to other small outdoor waters across the EU. For use in registration the RMS recommends to study dissipation of BYI 02960 in outdoor surface waters under various conditions. Current practice for soil are degradation studies in 4 soils, of which the geometric mean degradation rate is determined. The geometric mean value is used for registration purposes. In analogy, we recommend to calculate a geometric mean DT_{50} of more than one system, representing small surface waters, e.g. two to four. The geometric mean DT_{50} should be calculated from DT_{50} values at 20°C.

Concluding: The study can be used for risk assessment but only in case i) the half-lives derived are calculated back to 20 °C (as well as possible, the weekly temperature measurements should preferably be supplemented, e.g. with temperature measurements nearby and correlating these to the experiment, because DT_{50} is a function of temperature and ii) as one of the 2-4 systems providing DT_{50} values to be used for calculating a geometric mean DT_{50}. The DT_{50} values of this study are system specific and cannot be generalised to other small outdoor waters across the EU.

B.8.4.4 Summary and assessment

Hydrolysis

BYI 02960 proved to be stable under sterile hydrolytically conditions at all pHs.

Photo degradation in water

Sterile buffer

[^{14}C] BYI 02960 photolytically degraded in sterile buffer (pH 7) with a half-life of 13.8 experimental hours. Based on this finding, BYI 02960 should degrade within a few days in the aqueous environment if exposed to sunlight. The major degradates (>10% of applied radioactivity) were identified as [^{14}C] BYI 02960-succinamide and [^{14}C] BYI 02960-azabicyclosuccinamide. The half-life was calculated to be equivalent to 2.7 days calculated for Athens, Greece and 3.4 days calculated for Lodon, U.K..

Natural waters

BYI 02960 photolytically degraded in sterile natural water with a half-life of 14.0 experimental hours. The major degradates (>10% of applied radioactivity) were identified as BYI 02960-succinamide and BYI 02960-azabicyclosuccinamide. A minor degradate was identified as BYI 02960-deschlorohydroxy-succinamide. In the dark controls BYI 02960 was stable. Based on the experimental half-life of 14.0 hours, the half-life of BYI 02960 under environmental conditions in Tokyo, Japan was calculated to be 3.8 days. The phototransformation study in natural water is regarded more relevant for the aqueous environment as the pure and sterile buffer study.

Ready biodegradability

A respective study was not performed. The parent compound BYI 02960 is considered to be “Not Readily Biodegradable.

Water/sediment studies

Five different water/sediment studies were submitted in the dossier. An anerobic water sediment study, two aerobic water sediment studies (one with one label and one with two labels). The fourth water sediment study was with the metabolite DFA. The final study was an outdoor microcosm study.

Anaerobic conditions

BYI 02960 dissipated from aqueous phase to sediment with a half-life of 7.2 and 9.6 days for Lawrence and Pikeville test system, respectively. With respect to the entire test system, BYI 02960 is regarded stable under anaerobic condition, no major metabolite were formed.

Aerobic conditions

[PYR] BYI 02960 is microbially degraded in aerobic water/sediment systems. The DT_{50} values for BYI 02960 in the entire water/sediment systems were 193.1 and 246.9 days for Hönniger Weiher and Angler Weiher, respectively. The only major transformation products were to carbon dioxide and formation of NER .

[FUR] and [ETH] BYI 02960 is translocated from the water phase into the sediment where it is slowly degraded and mineralized. Major transformation products were mineralization to carbon dioxide, formation of NER and one metabolite, DFA, (max. 6.9% of AR). The DT_{50} values for BYI 02960 in the entire water/sediment systems were 208.2 [FUR], 202.4 [ETH] and 246.1 [FUR], 285.0 [ETH] days for Hönniger Weiher and Angler Weiher, respectively.

The dissipation of DFA from the supernatant water phase was characterized by translocation into the sediment and by slowly degradation. With the exception of mineralization to carbon dioxide and formation of NER no major metabolite was found. The DT_{50} values for DFA in the entire water/sediment systems were 106.5 (persistence), 109.0 (modelling) and 967.1 (persistence) 567.2 (modelling) days for Hönniger Weiher and Angler Weiher, respectively.

Microcosm study

BYI 02960 dissipated from the supernatant water phase with a mean DT_{50} of 81 days due to translocation into the sediment and by degradation. The overall degradation (mean of 95.1 days) was faster under the prevailing outdoor conditions in comparison to the laboratory water sediment studies. Considering that BYI 02960 is rapidly degraded by photolysis there may be an enhanced degradation effect of sunlight under the outdoor test conditions.

The degradation route of BYI 02960 in aqueous environments is shown in Figure B.8.4.4-01.

Figure B.8.4.4-01 Proposed route of degradation of BYI 02960 in water/sediment systems (BYI 02960 rapidly partitioned into the sediment phase, DFA is mainly present in water phase)

Note: The degradates to be observed as well as the given maximum values are highly dependent on radiolabel and kind of study considered; Ph = photo-transformation

B.8.5 Impact on water treatment procedures (Annex IIIA 9.2.2)

No information is provided on the fate of BYI 02960 in wastewater treatment plants. The effects on activated sludge are reported under B.9.10.1.

STUDY IIIA 9.2.2/01

Characteristics

reference	:	Schäfer, D.; Ströch, K.; Garside C.M. 2014	statement	:	PEC at drink water abstraction points
year of execution	:	2014			
GLP statement	:	no			
guideline	:	not available			
test substance	:	BYI 02960 and metabolites	acceptability	:	**acceptable**

The applicant provided a statement including an assessment that, based on the obtained PEC_{gw} and PEC_{sw} concentrations of the parent substance and metabolites, the concentrations are below the 0.1 µg/L...

Concentrations in groundwater or surface water of the active substance flupyradifurone and its metabolites at raw water abstraction points will be clearly below 0.1 µg/L, or maximum about 0.1 µg/L for the non-relevant metabolite DFA in groundwater. It is therefore highly unlikely that water treatment processes such as ozonation or chlorination will result in the formation of significant levels of by-products that would require human or animal health risk assessment. Consequently, further information on the effect of water treatment processes on the nature of residues present in surface water and groundwater is not considered necessary.

REMARKS RMS

The RMS agrees with the applicant and statement that the concentration of the active substance and metabolites will not exceed 0.1 µg/L at drinking water abstraction points.

B.8.6 Predicted environmental concentrations in surface water, in sediment and in groundwater (PECsw, PECsed, PECgw) (Annex IIIA 9.2.1, 9.2.3)

B.8.6.1 Predicted concentrations in surface water (Annex IIIA 9.2.3)

Calculation of PEC values for the active substance and metabolites according to FOCUS

$FOCUS_{sw}$ is a four step tiered approach:

Step 1: In this, the most conservative step, all inputs are considered as a single loading to the water body and a worst-case PEC_{sw} and PEC_{sed} is calculated.

Step 2: A refinement is made whereby individual loadings into the water body from different entry routes are considered. Scenarios are also considered for Northern and Southern Europe separately but no specific crop scenarios are defined.

Step 3: An exposure assessment using realistic worst-case scenarios is made. The scenarios are representative of agricultural conditions in Europe and consider weather, soil, crop and different water-bodies. Simulations use the models PRZM, MACRO and TOXSWA.

Step 4: PEC values are refined by considering mitigation measures or specific scenario descriptions on a case-by-case basis.

The PEC values in water and sediment were calculated at Step 1, 2, 3 and 4 for the parent substance. Only global maximum values were calculated, which can be used as conservative estimates of the actual and time-weighted average values assuming no degradation. Study design, compound characteristics and application were the same as for the PEC_{sw} calculations as for the PEC_{sed}.

Note: There are currently no agreed European guidelines for the assessment of exposure of surface water from the use in glasshouses, therefore it was assumed that the use in glasshouses on lettuce is covered by the outdoor field use even considering the different use pattern.

Materials and Methods

Predicted environmental concentrations in surface water and sediment (PEC_{sw} and PEC_{sed}) of BYI 02960 have been calculated for the use in hop and lettuce in Europe employing the tiered FOCUS Surface Water approach. All relevant entry routes of a compound into surface water (principally a combination of spray drift and runoff/erosion or drain flow) were considered in these calculations.

Details of the parameters used in the calculations are summarised in Table B.8.6.1-01.

Table B.8.6.1-01 Comparison of actual and calculated use pattern (for FOCUS step 1 & 2)

Individual Crop	FOCUS Crop Used for Interception	Application				Amount Reaching the Soil per Season application [g a.i. /ha]
		Rate per Season [g a.i. /ha]	Interval [days]	Plant Interception [%]	Growth Stage	
Hops, GAP	hops	1× 150	-	-	31-75	-
Hops, FOCUS simulation		1× 150	-	50 (average crop cover)	31-75	1 x 75

At Step 4, the mitigation according to the FOCUS Landscape and Mitigation Factors report (FOCUS 2007) is assessed. For this purpose, calculations using mitigation measures for drift and runoff were defined. The relevant parameters are summarised in Table B.8.6.1-03 and Table B.8.6.1-04.

Table B.8.6.1-03 Mitigation approaches used

Crop	Buffer length	Mitigation type	Drift reducing nozzles
Hops	5 m	Spraydrift	0%, 50%, 75% 90%
	10 m	Spraydrift & RunOff	0%, 50%, 75% 90%
	15 m	Spraydrift & RunOff	0%, 50%, 75% 90%
	20 m	Spraydrift & RunOff	0%, 50%, 75% 90%
Lettuce	5 m	Spraydrift	0%, 50%, 75% 90%
	10 m	Spraydrift & RunOff	0%, 50%, 75% 90%
	15 m	Spraydrift & RunOff	0%, 50%, 75% 90%
	20 m	Spraydrift & RunOff	0%, 50%, 75% 90%

Table B.8.6.1-04 Runoff mitigation parameters used for the assessment

Crop	Fraction in reduction		10 m	15 m	20m
Hops	Runoff:	Volume	0.60	0.80	0.80
		Flux	0.60	0.80	0.80
	Erosion:	Mass	0.85	0.95	0.95
		Flux	0.85	0.95	0.95
Lettuce	Runoff:	Volume	0.60	0.80	0.80
		Flux	0.60	0.80	0.80
	Erosion:	Mass	0.85	0.95	0.95
		Flux	0.85	0.95	0.95

Compound specific input data are summarised in Table B.8.6.1-05.

Table B.8.6.1-05 Substance specific and model related input parameter for PEC_{sw} calculation of BYI 02960

	R1 (stream, 1st)	0.708	0.354	0.177*	0.071*	0.048	0.025	0.017	0.016

* reduction of the overall drift percentage is >95%, compared to STEP3, in case drift leads to PECsw max.

The mitigation from 10 m onwards includes spray drift and concurrent run-off buffer. However, as can be seen from the linear decrease of PEC_{sw} values with increasing drift reduction, the PEC_{sw} is always drift dominated and the run-off buffer does not drive the PEC_{sw}.

The step 4 PEC_{sw} for the pond scenario with 5 m buffer and 0% drift reduction is higher compared to the step 3 value. This is due to the default buffer width of 6 m already included in step 3 calculations resulting in a lower drift percentage of 2.63% compared to 2.97% in step 4.

Table B.8.6.1-11 Maximum PEC_{sw} and PEC_{sed} values of BYI 02960 at Step 4 including drift reduction (without buffer) – Lettuce 1 (1 x 125 g/ha, field use)

Remarks

The RMS agrees with the risk assessment done by the applicant and recalcultated the FOCUS surface water step 1, 2, 3 and 4 model calculations and obtained the same results as the applicant. The obtained values by the applicant were checked by the RMS with Swash version 3.1 and Swan 1.1.4.

STUDY IIIA, 9.8/01 and STUDY 9.8/02

For BYI 02960, the metabolites difluoracetic acid (DFA), 6-chloronicotinic acid (6-CNA) and BYI 02960-succinamide and BYI 02960-azabicyclosuccinamide were assessed.

year of execution	:	2012(9.8/01) and 2013 (9.8/02)	acceptability	:	**acceptable**
test substance	:	difluoracetic acid (DFA), 6-chloronicotinic acid (6-CNA) and BYI 02960-succinamide and BYI 02960-azabicyclosuccinamide			

Materials and Methods: PECsw for the metabolites were calculated using the approach, scenarios and application rates described for the calculations for the parent compound in study IIA, 9.7/01. Input parameters for the metabolites are described in Table B.8.6.1-16.

Table B.8.6.1-16 Substance specific and model related input parameters for PECsw calculation

Parameter	Unit	DFA	6-CNA	BYI 02960-succinamide	BYI 02960-azabicyclo-succinamide

Soil	%	33.9	17.1	0	0

* The DT50 soil was set to 0.1 d as the model STEP2 does not accept 0 d.

Findings:

Step 1 and 2: The maximum PEC values for the metabolites of BYI 02960 at Step 1 and Step 2 are given in Table B.8.6.1-17. Time dependent PEC values or time-weighted average concentrations are not included in this summary, because they were not used in the risk assessment. However, all values are given in the report.

F = Field use
1) Maximal 1 use per 24 month (minimal crop cover)
2) Maximal 1 use per 12 month (average crop cover)
* First or second cropping per year

Remarks

The RMS agrees with the risk assessment for the metabolites done by the applicant. RMS recalcultated the FOCUS PEC_{sw} and PEC_{sed} step 1 and 2 model calculations and obtained the same results as the applicant.

Materials and Methods

The predicted environmental concentrations in groundwater (PEC_{gw}) for BYI 02960 and its metabolites were calculated using the simulation model FOCUS PEARL (version 4.4.4) and FOCUS PELMO (4.4.3). Detailed application data used for simulation of PEC_{gw} are compiled in Table B.8.6.3-01 and B.8.6.3-02. Simulations were conducted for annual applications as well as applications performed every second year.

Table B.8.6.3-01 Comparison of simulated and actual use pattern

Individual Crop	FOCUS Crop Used for Interception	Application				Amount Reaching the Soil per Season application [g a.s. /ha]
		Rate per Season [g a.s. /ha]	Interval [days]	Plant Interception [%]	BBCH Stage	
Hops, GAP	-	1 × 150	-	60	31 – 75	1 × 60.00
Tier 1, Tier 2b (TDS)						
Hops (every ear), Simulation 1	Vines	1 × 150	-	60	31 – 75	1 × 60.00
Hops (every 2nd year), Simulation 2	Vines	1 × 150	-	60	31 – 75	1 × 60.00
Tier 2a (DFOP)						
Hops (every ear), Simulation 1	Vines	1 × 150	-	60	31 – 75	68.4 [s] / 51.6 [f]
Hops (every 2nd year), Simulation 2	Vines	1 × 150	-	60	31 – 75	68.4 [s] / 51.6 [f]

[f] used for fast compartment
[s] used for slow compartment

Application dates for the simulation runs were defined following the crop event dates of the respective crop and scenario as given by FOCUS (2009).

Table B.8.6.3-02 First application dates and related information for BYI 02960 as used for the simulation runs (offset is relevant only for relative application dates, two sets of data are provided for crops with two seasons)

Individual crop	Hops	Hops
Repeat Interval for App. Events	Every Year	Every 2nd Year
Application Technique	Spray	Spray
Absolute / Relative to	Emergence	Emergence
Scenario	1st App. Date/(Julian day)/Offset to crop event	
	First tier/ Second tier	
Chateaudun	29 April (119) 28	29 April (119) 28
Hamburg	29 May (149) 28	29 May (149) 28
Jokioinen	-	-
Kremsmuenster	29 May (149) 28	29 May (149) 28
Okehampton	-	-
Piacenza	29 April (119) 28	29 April (119) 28
Porto	12 Apr (102) 28	12 Apr (102) 28

Thiva	12 Apr (102) 28	12 Apr (102) 28

Further input parameters for PEC_{gw} modelling of BYI 02960 are summarised in Table B.8.6.3-03 for BYI 02960 and in Table B.8.6.3-04 for the metabolites. Parameters used for degradation pathway in PEARL and PELMO are depicted in Table B.8.6.3-05.

For Tier 1, a geometric mean of half-lives derived from SFO and from the slow compartment of the DFOP model was used to obtain a conservative model input.

For Tier 2a, (DFOP) according to FOCUS (2009), DFOP degradation kinetics was considered in leaching modelling based on the procedure described in FOCUS (2006).

To obtain common DFOP parameters over all soils the following procedure was applied: Firstly, all degradation curves following SFO kinetics on Tier-1 were converted to an equivalent DFOP model where the Tier-1 SFO-DT_{50} was assigned equally (g=0.5) to the slow and fast degrading compartment. For those soils where the slow compartment of DFOP was already used for modelling at Tier-1, the corresponding shorter DT_{50} of the fast compartment and g (fraction of total amount applied to the compartment) of the DFOP fit were additionally considered. Finally, the DFOP parameters were calculated as geometic over all soils for the rate and arithmetic mean for the g value (see Table B.8.6.3-03a and Table B.8.6.3-03b).

Table B.8.6.3-03a DFOP parameters for tier-2a leaching calculations

Geometric mean				**33.4**		**94.8**		
Arithmetic mean								**0.43**

For leaching modelling the application rate was doubled and assigned to both compartments according to g of 0.43. Then, two separate leaching simulations were performed: one for the fast compartment using DT_{50fast} of 33.4 days (k_1 0.0207 d^{-1}) and one using DT_{50slow} of 94.8 days (k_2 0.00731 d^{-1}). Both PEC_{gw} values were summed up and divided by two to get the final result.

Tier 2b (TDS): Time dependent sorption (TDS) data of BYI 02960 on four soils were derived via curve fitting (study IIA, 7.4.1/05). These parameters constitute the prerequisite to adequately address TDS processes in regulatory exposure modelling (Beulke, S. and van Beinum, W. 2012)[3]. Experimental soil data were re-calculated to fit the TDS model, resulting in a geometric mean DT_{50_eq} of 57.9 days, an arithmetic mean K_{OM_eq} of 47.5 L/kg, an arithmetic mean f_ne of 0.5821, a geometric mean $k_{_des}$ of 0.0309 and an arithmetic mean Freundlich exponent of 0.8605 from the optimized parameters of the four data sets. The PECgw calculations given in this part are based on the average/geometric mean parameters obtained from the individual soil. At the end of this paragraph a comparison with the PECgw from each separate soil data set is given as was proposed in the draft guidance on TDS (Beulke, S. and van Beinum, W. 2012).

[4] Schriever, C., Gottesbüren, B., Ebert, D., Sur, R. Schmitt, W. (January 2013). ECPA background paper. Plant uptake of compounds via roots sytem – A hydroponic test system to determine plant uptake as input parameter for leaching models.

This is report give the results from 22 anonymised compounds that were tested in a hydroponic system to determine the plant uptake factore (PUF). The conclusion is that the PUF, irrespective of the Kow and pKa, of the 22 tested compounds is on average 1. The applicant intends to use this fact for the PUF for the metabolites DFA and 6-CNA can be set on 0.5. The RMS cannot accept this report since used compounds are anonymized, the tests are not concducted under GLP, an adopted test guideline for the hydroponic test is not available. Additionally, the specific metabolites DFA and 6-CNA were not tested in the this test system.

Thiva	0.178	0.154	*0.073*	*0.058*

In italics: values pass the trigger of 0.1 µg/L

Considering the Tier 1 simulations predicted concentrations of BYI 02960 in groundwater are below the trigger of 0.1 µg/L in the scenario Sevilla (model PELMO) when applied every year and in scenarios Sevilla and Thiva (both PEARL and PELMO) and Porto (PEARL), when applied every second year.

Higher tier calculations have additionally been performed at Tier 2a using DFOP simulations and Tier 2b using TDS.

Table B.8.6.3-07 Tier 2a (DFOP) - PEC_{gw} of BYI 02960 – Use in Hops

Scenario	BYI 02960			
	Hops (every year), 1 x 150 g/ha		Hops (every 2nd year), 1 x 150 g/ha

Thiva	0.108	*0.094*	*0.045*	*0.036*

In italics: values pass the trigger of 0.1 µg/L

When considering the use of DFOP kinetics predicted concentrations of BYI 02960 in groundwater are below the trigger of 0.1 µg/L in the scenario Sevilla and Thiva (model PELMO) when applied every year and in scenarios Porto, Sevilla and Thiva (both PEARL and PELMO) and Piacenza (PEARL), when applied every second year.

Table B.8.6.3-08 Tier 2b (TDS) - PEC_{gw} of BYI 02960 – Use in Hops

Scenario	BYI 02960			
	Hops (every year), 1 x 150 g/ha, 60 % interception		Hops (every 2nd year), 1 x 150 g/ha, 60 % interception	
	PEARL PEC_{gw} [µg/L]	PELMO PEC_{gw} [µg/L]	PEARL PEC_{gw} [µg/L]	PELMO PEC_{gw} [µg/L]
Châteaudun	0.112	0.094	*0.042*	*0.032*
Hamburg	0.156	0.144	*0.061*	*0.053*
Kremsmuenster	0.117	0.134	*0.042*	*0.047*
Piacenza	0.109	0.152	*0.040*	*0.063*
Porto	*0.048*	*0.075*	*0.017*	*0.025*
Sevilla	*0.039*	*0.006*	*0.012*	*0.002*
Thiva	*0.026*	*0.020*	*0.008*	*0.006*

In italics: values pass the trigger of 0.1µg/L

When considering TDS behaviour the predicted concentrations of BYI 02960 in groundwater are below the trigger of 0.1 µg/L in the scenario Porto, Sevilla and Thiva (models PEARL and PELMO) when applied every year and in all scenarios (both PEARL and PELMO), when applied every second year.

Conclusion

A safe use has been demonstrated as the trigger of 0.1 µg/L is met at tier 1, considering application every year, for the scenario Sevilla (PELMO). For the higher tier calculations applying DFOP the trigger was met in Sevilla and Thiva for annual applications. When considering higher tier calculations with TDS the trigger was met in all scenarios for annual uses and all scenarios for use every second year.

Remarks

The RMS agrees with the risk assessment conducted for BYI 02960 in hops. RMS recalculated the PECgw and these were all similar. The RMS also agrees with the used higher tier approach.

Materials and Methods

The predicted environmental concentrations in groundwater (PEC_{gw}) for BYI 02960 were calculated using the simulation model FOCUS PEARL (version 4.4.4) and FOCUS PELMO (4.4.3). Detailed application data used for simulation of PEC_{gw} are compiled in Table B.8.6.3-09 and Table B.8.6.3-10.

Although there is no currently agreed model for simulating groundwater concentrations following the use in greenhouses as a conservative approach the simulation was performed as an outdoor application considering two applications in accordance with the GAP.

Table B.8.6.3-09 Comparison of simulated and actual use pattern (outdoor use)

Individual Crop	FOCUS Crop Used for Interception	Application				Amount Reaching the Soil per Season application [g a.s. /ha]
		Rate per Season [g a.s. /ha]	Interval [days]	Plant Interception [%]	BBCH Stage	
Lettuce 1 (GAP, every year)	-	1 × 125	-	70	41 - 49	1 × 37.5
Lettuce 1 (GAP, every 2nd year)	-	1 × 125	-	25	12 - 49	1 × 93.75
Tier 1, Tier 2b (TDS)						
Lettuce 1 (every year) (early and late), Simulation 1	Cabbage	1 × 125	-	70	41 - 49	1 × 37.5
Lettuce 1 (every 2nd year) (early and late), Simulation 2	Cabbage	1 × 125	-	25	12 - 49	1 × 93.75
Tier 2a (DFOP)						
Lettuce 1 (every year) (early and late) Simulation 1	Cabbage	1 × 125	-	70	41 - 49	42.75[s] / 32.25[f]
Lettuce 1 (every 2nd year) (early and late) Simulation 2	Cabbage	1 × 125	-	25	12 – 49	106.875[s] / 80.625[f]

F = Field use (GAP: "Lettuce 1" = 1 x 125 g/ha)
[f] used for the fast compartment
[s] used for the slow compartment

Table B.8.6.3-10 Comparison of simulated and actual use pattern (glasshouse use)

Individual Crop	FOCUS Crop Used for Interception	Application				Amount Reaching the Soil per Season application [g a.s. /ha]
		Rate per Season [g a.s. /ha]	Interval [days]	Plant Interception [%]	BBCH Stage	
Lettuce 2 (every year), GAP	-	2 × 125	10	2 x 25	12 - 49	2 × 93.75
	Tier 1, Tier 2b (TDS)					
Lettuce 2 (every year) early	Cabbage	2 × 125	10	2 x 25	12 - 49	2 × 93.75
Lettuce 2 (every year) late	Cabbage	2 × 125	10	2 x 25	12 - 49	2 × 93.75
	Tier 2a (DFOP)					
Lettuce 2 (every year) ealy	Cabbage	2 × 125	10	2 x 25	12 - 49	2×106.875[s] / 2× 80.625[f]
Lettuce 2 (every year) late	Cabbage	2 × 125	10	2 x 25	12 - 49	2×106.875[s] / 2× 80.625[f]

G = Glasshouse use (GAP: "Lettuce 2" = 2 x 125 g/ha)
[f] used for the fast compartment
[s] used for the slow compartment

Application dates for the simulation runs were defined following the crop event dates of the respective crop and scenario as given by FOCUS (2009). In this assessment the first and the second cropping per year of lettuce were calculated separately (Table B.8.6.3-11).

Table B.8.6.3-11 First application dates and related information for BYI 02960 as used for the simulation runs (two sets of data are provided for crops with two crops per season)

Individual crop	Lettuce 1, 1st cropping	Lettuce 1, 2nd cropping	Lettuce 1, 1st cropping	Lettuce 1, 2nd cropping	Lettuce 2, 1st cropping	Lettuce 2, 2nd cropping

Further input parameters for PEC_{gw} modelling of BYI 02960 are summarised above in Table B.8.6.3-03 for BYI 02960 and in Table B.8.6.3-04 for the metabolites. Parameters used for degradation pathway in PEARL and PELMO are depicted in Table B.8.6.3-05.

Findings

The 80th percentile concentrations of BYI 02960 for the field and glasshouse uses in lettuce are given in the following tables.

Table B.8.6.3-12 Tier 1 PEC_{gw} of BYI 02960 – Use in Lettuce 1, single application (field use), every year

Scenario	BYI 02960 (field use / every year)

Thiva	0.606	0.438	-	-

In italics: values pass the trigger of 0.1µg/L

For the greenhouse use in lettuce, using the Tier 2a approach (DFOP) the trigger is met for the scenario Sevilla for annual application even considering the conservative use of the outdoor model.

Table B.8.6.3-20 Tier-2b (TDS) PEC_{gw} of BYI 02960 – Use in Lettuce 2, multiple applications (glasshouse use)

Scenario	BYI 02960 (glasshouse use / every year / TDS)			
	Lettuce 2, 1st cropping, every year, 2 x 125 g/ha		Lettuce 2, 2nd cropping, every year, 2 x 125 g/ha	
	PEARL PEC_{gw} [µg/L]	PELMO PEC_{gw} [µg/L]	PEARL PEC_{gw} [µg/L]	PELMO PEC_{gw} [µg/L]
Châteaudun	0.245	0.155	0.334	0.214
Hamburg	0.677	0.520	0.905	0.784
Jokioinen	0.185	0.145	-	-
Kremsmuenster	0.475	0.404	0.568	0.502
Porto	0.259	0.355	0.508	0.627
Sevilla	*0.006*	*0.001*	*0.007*	*0.001*
Thiva	0.181	0.119	-	-

In italics: values pass the trigger of 0.1µg/L

For the greenhouse use in lettuce, using the Tier 2b approach (TDS) the trigger is met for the scenario Sevilla for annual applications, even considering the conservative use of the outdoor model.

Conclusion

For all the uses considered safe use can be demonstrated in at least 1 scenario even considering tier 1 calculations. When higher tier (Tier 2) simulations are considered the calculated PEC_{gw} is less than the trigger in several scenarios.

Remarks

The RMS agrees with the risk assessment conducted for BYI 02960 in lettuce. RMS recalculated the PECgw and these were all similar. The RMS also agrees with the used tiered approach.

PECgw for BYI 02960 metabolites in hops

Materials and Methods

PEC_{gw} for the metabolites were calculated using the approach, scenarios and application described for the calculations for the parent compound in studies IIIA 9.6.1. Compound specific input data for the metabolites are summarised together with the data of the parent compound in Table B.8.6.3-03b and Table B.8.6.3-04. Metabolites were simulated in the degradation schemes implemented in Pearl and Pelmo.

Findings: The 80th percentile concentrations for BYI 02960 metabolites for the different EU scenarios are presented in Table B.8.6.3-21 for Tier 1.

Table B.8.6.3-21 Tier 1 PEC_{gw} of BYI 02960 metabolites (after application of 150 g BYI 02960/ha) in hops

In italics: values pass the trigger of 0.1µg/L
In bold: values pass the trigger of 0.75 µg/L

PEC_{gw} values for the metabolite DFA are above 0.1 µg/L for all scenarios (both PEARL and PELMO), and for applications taking place every year or every 2nd year, respectively. PEC_{gw} values for the metabolite 6-CNA are below 0.1 µg/L for all scenarios (both PEARL and PELMO) for applications taking place every year or every 2nd year, respectively. There are no concerns for groundwater for this metabolite.

Additionally, for difluoroacetic acid (DFA), calculations combined with higher tier (DFOP and TDS) for parent have been performed, the results are summarized below Table B.8.6.3-22 and Table B.8.6.3-23.

Table B.8.6.3-22 Tier 2a (DFOP): PEC_{gw} of difluoroacetic acid (DFA) in hops (1 x 150 g/ha of parent)

In italics: values pass the trigger of 0.1µg/L
In bold: values pass the trigger of 0.75 µg/L

Conclusion

The groundwater concentration of the metabolite 6-CNA did not exceed the trigger in any scenario at Tier 1. The PEC in groundwater for the metabolite DFA may exceed the 0.1 µg/L and also the 0.75 µg/L trigger, but the concentration was < 10 µg/L in all scenarios. The relevance of the metabolite has been assessed in accordance with Sanco/221/2000 –rev.10 (2003): "Guidance Document on the Assessment of the Relevance of Metabolites in Groundwater", and the metabolite was not relevant in terms of efficacy (see IIA, 8.14.1), genotoxicity and toxicity (see IIA, 5.8/01 - 05) and has also been considered in the dietary risk assessment (see IIA, 6.9).

Please note: DFA was considered in the dietary risk assessment since it is a constituent of the plant residue definition.

Remarks

The RMS agrees with the risk assessment conducted for the metabolites of BYI 02960 in hops. RMS recalculated the PECgw and these were all similar. The RMS also agrees with the used higher tiered approach, though, based on the fact that DFA can be considered a non relevant metabolite with regard to groundwater exposure, these calculations are not required.

~~The RMS did not yet recalculated the PECgw based on the not acceptance of the Schriever et al study. Based on the expert meeting results on the discussion on aged sorption the values for PECgw will be updated and the adjusted PUF- for the metabolites will be included in these new model calculations.~~

Materials and Methods

PEC_{gw} for the metabolites were calculated using the approach, scenarios and application described for the calculations for the parent compound in Point 9.6.1. This includes the higher tier approaches for the parent substances using DFOP kinetics or TDS. Compound specific input data for the metabolites are summarised together with the data of the parent compound in Table B.8.6.3-03b and Table B.8.6.3-04.

Findings

The PEC_{gw} values for the metabolites for the different EU scenarios are presented for field and glasshouse uses in the following tables.

Table B.8.6.3-24 Tier 1 PEC_{gw} of BYI 02960 metabolites (field use in lettuce 1, 1st cropping)

In italics: values pass the trigger of 0.1 µg/L
In bold: values pass the trigger of 0.75 µg/L

Considering the use in the glasshouses the PEC_{gw} values for the metabolite DFA are above 0.1 µg/L for all scenarios (both PEARL and PELMO), and for applications taking place every year, at Tier 1 and Tier 2.

PEC_{gw} values for the metabolite 6-CNA are below 0.1 µg/L for all scenarios (both PEARL and PELMO) at tier 1, and for applications taking place every year, respectively. There are no concerns for groundwater for this metabolite.

Conclusion

The groundwater concentration of the metabolite 6-CNA did not exceed the trigger in any scenario. The PEC in groundwater for the metabolite DFA may exceed the 0.1 µg/L and also the 0.75 µg/L trigger, the concentration was < 10 µg/L in all scenarios The relevance of the metabolite has been assessed in accordance with Sanco/221/2000–rev.10 (2003): "Guidance Document on the Assessment of the Relevance of Metabolites in Groundwater", and the metabolite was not relevant in terms of efficacy (see IIA, 8.14.1), genotoxicity and toxicity (see IIA, 5.8/01 - 05) and has also been considered in the dietary risk assessment (see IIA, 6.9). Please note: DFA was considered in the dietary risk assessment since it is a constituent of the plant residue definition.

Remarks

The RMS agrees with the risk assessment conducted for the metabolites of BYI 02960 in lettuce. RMS recalculated the PECgw and these were all similar. The RMS also agrees with the used higher tiered approach, though, based on the fact that DFA can be considered a non relevant metabolite with regard to groundwater exposure, these calculations are not required. Since the PECgw concentration of DFA exceeds the 0.75 µg/L trigger for many scenarios the RMS conducted a consumer risk exposure with the highest PECgw for DFA of 7.008 µg/L (Hamburg scenario, Tier 2a (DFOP) second cropping). Drinking 2 L of groundwater with 7.008 µg/L DFA resulted in 0.23% of the average daily intake (ADI) for adults and 0.52% filling for toddlers thus fulfilling the criteria for consumer exposure.

~~The RMS did not yet recalculated the PECgw based on the not acceptance of the Schriever et al study. Based on the expert meeting results on the discussion on aged sorption the values for PECgw will be updated and the adjusted PUF for the metabolites will be included in these new model calculations.~~

Introduction

The previously reported tier 2b TDS results were calculated with the averages of the obtained parameter results of all the individual soils. The EU consultation indicated that the results of the results individual sets of parameters shoul be compared with the averages of the parameters of all soils. From the individual results per soil the median should calculated and compared with the results of the average parameters. This is done in the following study. The draft guidance proposal by Beulke and van Beinum (2012) was followed to present calculations of PECgw using time dependent sorption

parameters, i.e. compare median PECgw results from 4 individual soil parameter sets with PECgw results from a mean data set.

Summary

Predicted environmental concentrations of the active substance flupyradifurone and its metabolites difluoroacetic acid (DFA) and 6-chloronicotinic acid (6-CNA) in groundwater recharge (PECgw) were calculated for the use in Europe, using the simulation models FOCUS PEARL 4.4.4 (Leistra et al. 2001) and FOCUS PELMO 5.5.3 (Jene 1998; Klein 1995, 1999, 2011). PECgw were evaluated as the 80th percentile of the mean annual leachate concentration at 1 m soil depth. Model parameters and scenarios consisting of weather, soil, and crop data were used as proposed by FOCUS (2009).

The use in lettuce and hops was investigated. Main substance parameters used in this assessment are given in Table B.8.6.3-32 and Table B.8.6.3-33. Parameters for Flupyradifurone represent Tier 2 parameterization using time dependent sorption. The draft guidance proposal by Beulke and van Beinum (2012) was followed to present calculations of PECgw using time dependent sorption parameters, i.e. compare results from individual parameter sets per soil with the overall average parameters.

Detailed application parameters are presented in Table B.8.6.3-01, Table B.8.6.3-02, Table B.8.6.3-09, Table B.8.6.3-10 and Table B.8.6.3-11.

Table B.8.6.3-32 Degradation and time dependent sorption data of flupyradifurone for individual soils and the overall mean parameter set.

Maximum median PECgw results from 4 individual soil parameter sets are presented together with PECgw results from a mean data set in the following tables Table B.8.6.3-35 and Table B.8.6.3-36. PECgw calculations using time dependent sorption parameter sets from 4 individual soils may yield in some cases higher values, however, these are not meant to base a risk management decision upon Beulke and van Beinum, 2012.

Modelling approach

Time-dependent sorption (TDS) data of Flupyradifuroneon four soils were derived via curve fitting (Sur and Scherr, 2012). These parameters constitute the prerequisite to adequately address TDS processes in regulatory exposure modelling. TDS was evaluated according to the model of Boesten et al. (1989) implemented in the groundwater leaching models PEARL and FOCUS-PELMO (FOCUS, 2009). The determination of the TDS parameters followed the guidance of Beulke et al. (2010). This guidance was adopted later and a revised version was published in 2012 (Beulke and van Beinum, 2012). Therefore, a new evaluation was conducted to follow the new requirements by Scherr (2014).

The experimental raw data were pre-processed to calculate the concentration in the $CaCl_2$ desorption solution, and the total mass. These data were used by Sur and Scherr (2012) and by Scherr (2012) to fit the TDS model using PEARLNEQ (Boesten et al., 2007).

The evaluation showed that the experimental data was well described by the TDS model, with excellent fits and reliable parameter estimates. The inferred parameters were

- the desorption rate constant kdes,
- the ratio between the Freundlich coefficients in the non-equilibrium and in the equilibrium compartment fne,
- the degradation half-life in the equilibrium compartment DT50eq,
- the organic matter normalized distribution coefficient in the equilibrium compartment Kom,eq,
- and the initial total mass in the system Mini.

The corresponding values for all soils are given in Table B.8.6.3-37 along with the χ2-error percentage value. Shown are the parameter estimations with the lowest out of four starting value combinations. Details of the starting value dependence can be retrieved from Scherr (2014). In general the starting values for fne and kdes had virtually no impact on the parameter estimates. Low values of χ2, i.e. <15 % point towards a good description of the model to the fitted data. Reliable parameter estimates are indicated by low values for the relative standard error (RSE) of the individual parameter estimates, also given in Table B.8.6.3-37. None of the RSE values exceeds the minimum criteria of ≤ 0.4 given in Beulke and van Beinum (2012).

The kinetic desorption rate constant kdes indicates a time scale of about 22 d, calculated as "pseudo half-life" for the exchange between equilibrium and non-equilibrium domain. The criterion for an acceptable range of kdes outlined in Beulke and van Beinum (2012) accounting for less than 0.5 (1/d) is met by the present evaluation.

Values for fne in the range of 0.3875 – 0.7808 indicate that the kinetically controlled "sorption capacity" is in the range of 39 - 78% of the instantaneous sorption capacity, and accounts on average for about

58%. The fitted values of fne are well below the criterion (i.e. fne < 10) given by Beulke and van Beinum (2012).

The DT50eq represents degradation in the equilibrium domain and accounts on average (geom. mean) for 57.9 d suggesting moderate degradation during the laboratory study.

Table B.8.6.3-37 Time-dependent sorption parameters of Flupyradifurone used for Tier 2a leaching (Scherr, 2014). Numbers in brackets indicate rel. std. error RSE for the individual parameter.

Soil	M_ini [µg]	k_des [1/d]	f_ne [-]	DT50_eq [d]	Kom_eq [L/kg]	Chi^2-err [%]

Method

The calculations were (where applicable) based on the maximum intended application rate together with the maximum intended number of applications per season and the minimum interval between two applications (where applicable).

Application dates for the simulation runs were defined following the crop event dates of the respective crop and scenario as given by FOCUS (2009). Crop interception was taken into account according to the BBCH growth stage, as recommended by FOCUS (2010).

Simulation Period

The simulations are carried out over 26 years for pesticides which are applied every year. The simulation length increases to 46 and 66 years for pesticides which are applied only every second and third year, respectively. The first 6 years are intended as a so called ‘warm up’ period. The following years are taken into account for the assessment of the potential leaching behaviour.

Compound Input Parameters

Substance parameters used as inputs in the simulations are summarised in Table B.8.6.3-38. Detailed information about the formation fractions and degradation rates is given in Table B.8.6.3-39.

Please note that any substance code in the following tables is just an internal identifier of the substance in the particular model and is not necessarily the same as the substance code as defined within the rest of this document.

Table B.8.6.3-38 Compound input parameters for flupyradifurone and its metabolites. sections with multiple values for individual soil parameter sets are initiated by a shaded row.

Molecule splitting with FOCUS-PELMO

The sum of molar formation fractions from the parent to both metabolites accounts for more than 1 (0.833 + 0.478), which cannot be implemented in PELMO. Therefore, with the standard approach only a single metabolite can be calculated in one PELMO run (in contrast to PEARL where individual formation fractions for metabolites are considered within the program code).

To calculate concentrations of both metabolites DFA and 6-CNA simultaneously in a single PELMO run the following procedure was applied: The molar mass of metabolite 6-CNA was artificially increased to account for the decreased formation fraction. By increasing the molar mass a heavier metabolite is formed. On a mass per volume assessment, i.e. the concentration in groundwater, this heavier metabolite equals the lighter one with a higher formation fraction.

A detailed example calculation for Tier 2a (TDS) is presented below.

DFA: The split degradation rate from Flupyradifurone (BYI 02960) to DFA is calculated as usual:

$$k_{FPF - DFA} = \ln 2 / (DT50soil\ 57.9\ d) \times 0.833 = 0.009972\ 1/d$$

6-CNA: Only a formation fraction of (1 - 0.833) is left to be used with 6-CNA, which is not sufficient, as the correct formation fraction is 0.478. Therefore, to guarantee a sufficient mass flux into this compartment, the molar mass of 6-CNA needs to be increased to obtain correct leaching concentrations of this metabolite:

$$k_{FPF - CNA} = \ln 2 / (DT50soil\ 57.9\ d) \times (1 - 0.833) = 0.001999\ d^{-1}$$

$$M_{auxiliary}\ (6\text{-}CNA) = M\ (6\text{-}CNA) \times 0.478 / (1 - 0.833) = 451\ g/mol$$

Results

A Tier 2b groundwater assessment is carried out for flupyradifurone, using time dependant sorption (TDS) parameters following the draft guidance proposal by Beulke and van Beinum (2012) to present calculations of PECgw using time dependent sorption parameters, i.e. compare median PECgw results from 4 individual soil parameter sets with PECgw results from a mean data set (Pearl 4.4.4: Table B.8.6.3-35; Pelmo 5.5.3: Table B.8.6.3-36). An overview of the maximum PECgw values obtained with

FOCUS PEARL 4.4.4 is given in Table B.8.6.3-40. Detailed FOCUS PEARL results for each scenario are listed in the following tables. Detailed results of the FOCUS PELMO 5.5.3 runs can be found in Table B.8.6.3-41. Representative examples. Detailed FOCUS PELMO results for each scenario are listed in the following tables.

Remarks

The calculations presented are according to the draft guidance on TDS. The results show that in some cases the median PECgw of the individual soil show higher values than PECgw obtained with the mean of the parameters.

B.8.7 Fate and behaviour in air (Annex IIA 7.2.2; Annex IIIA 9.3) OECD number 7.10

STUDY IIA, 7.10/01

Characteristics

reference	:	Hellpointer, E., 2010	purity	:	n.a.
year of execution	:	2010	test system	:	theoretical calculation
GLP statement	:	n.a.	hydroxyl rate constant	:	0.5-1.5 × 10^6 molecules (radicals)/cm^3
guideline	:	n.a.	half-life in air	:	4.4 – 13.1 hours
test substance	:	BYI 02960	acceptability	:	**acceptable**

Summary

Based on the estimation method according to structure-activity relationship (SAR) methods developed by Roger Atkinson and co-workers the chemical lifetime of the BYI 02960 in the air was assessed by the program AOPWIN™, version 1.92a (U.S. EPA, 2008). The half-life time ($t_{1/2}$) was estimated within a range of 4.4 hours (short-term scenario) to 13.1 hours (long-term scenario), depending on the mean concentration of hydroxyl radicals present in the troposphere.

In addition, BYI 02960 is susceptible to reactions with ozone, however, that attack and its resulting chemical half-life is considered to be slower by a factor of 2 to 10.

As a consequence of the short half-life in air, no long-range transport of BYI 02960 in the atmosphere is likely to occur nor an accumulation of BYI 02960 in the environmental compartment air. From the low vapor pressure of the substance it is concluded that very low, if any, quantities of BYI 02960 are expected to enter the atmosphere from volatilization.

Methods

There are different reaction mechanisms that may result in degradation of organic trace substances in the air being gaseous or bound to particles. According to the present knowledge mainly reactions with photochemical produced hydroxyl radicals, with nitrate radicals and ozone as well as direct photolysis are possibilities. The abiotic degradability and/or the reversal of that, the persistence of a substance, can be predicted if the reaction rate ki and the concentrations c(yi) of the potential reaction partners are known.

With an exception to be made for fully halogenated compounds, the abiotic degradability of an organic xenobiotic compounds can be well predicted from estimated reaction rate constants (ki) of the individual processes, and the concentrations c(yi) of the potential reaction partners, i.e. in particular the concentrations of OH radicals and ozone.

An experimental determination of the hydroxyl radical reaction rate (kOH), however, is very laborious and gas phase measurements are difficult for molecules showing a comparatively low vapor pressure. The approach of Atkinson et al. was based on a comprehensive set of experimental data to result in a quantitative structure-activity relationship (QSAR) mathematic model that allows for estimation by

calculation, starting from the molecular structure of a test compound. The calculation procedure has been transferred into the personal computer program "Atmospheric Oxidation Program" (AOP) by Meylan & Howard. The current version 1.92a (U.S. EPA, 2008) was used for the calculations. AOPWINTM requires only the chemical structure and atmospheric concentrations of the potential reaction partners as inputs.

The AOPWINTM estimation method adds up the partial reaction rates ki of the reaction of photochemically generated active species with subgroups of the test molecule (increments), resulting in the overall reaction rate. The following hydroxyl and/or ozone reactions are considered:

- hydrogen abstraction
- addition to double bonds
- addition to triple bonds
- reaction with N, S and hydroxyl groups
- addition to aromatic rings
- addition to fused rings

The listed increments (group rate constants for hydrogen abstraction, addition to double and triple bonds, ring systems, and reaction with heteroatoms) are compiled in a data base which additionally uses algorithms for consideration of adjacent groups (substituent factors) and the position of the attack to substituted aromatic rings (electrophilic substituent factors).

The reliability of the method used by AOPWINTM was examined by comparison of estimated and experimentally determined hydroxyl radical rate constants for 647 chemicals. More than 90 percent of the estimated rate constants were within a factor of two of the experiment value for these chemicals. More than 95 percent of the estimated values differed within a factor of three from measured values.

Considering the chemical structure of BYI 02960 it can be concluded that reactions with photochemical produced hydroxyl radicals will mainly determine its degradation rate (Ktotal, indirect photoreaction ≈ kOH) in the air. However, also reactions with ozone are expected to have a significant influence on the overall assessment.

Since a chemical in the troposphere is usually at a very low concentration and a steady-state concentration of OH radicals is produced by sunlight, the hydroxyl radical concentration can be treated as a constant so the reaction can be considered a pseudo first-order reaction.

As an estimate the maximum half-life in air from indirect photoreaction-oxidation processes can be derived under consideration of the concentration of hydroxyl radicals by the following formula:

The half-life in the troposphere, $t_{½} = \ln 2 / (k_{OH} \times [OH])$

where k_{OH} is the hydroxyl radical rate constant in units of cm^3/molecule-sec and [OH] is the hydroxyl radical concentration in units of molecules (or radicals) per cm^3. Thus, to calculate the half-life in the troposphere, one needs the estimated or measured rate constant of the chemical as well as some average OH radical concentration. In a U.S. EPA review by Leifer (no date), the author concluded that the diurnally and annually averaged 12-h daylight hydroxyl radical concentration of 1.5×10^6 molecules (radicals)/cm^3 should be used as the default in the AOPWIN program based upon data from Atkinson et al. of 1990. More recent reviews (Atkinson & Arey 2003) have suggested 2.0×10^6 molecules (radicals)/cm^3 12-hour daylight [OH].

Twelve hour daylight OH radical concentrations are reasonable for fast reacting chemicals but for chemicals that react more slowly (> a few days) 24 hours averages might be more appropriate. Atkinson (1985) suggested seasonally and diurnally 24 hour averaged hydroxyl radical concentrations at 298 K of 5×10^5 molecules/cm^3 in the northern hemisphere and 6×10^5 molecules/cm^3 in the southern hemisphere.

The AOPWIN program allows the user to select 12 or 24 hour time frames and any average hydroxyl radical concentrations. For the current report the default originally set at 1.5×10^6 molecules (radicals)/cm^3 per 12-h of daylight was taken for the short term, and 0.5×10^6 molecules (radicals)/cm^3 per day (24-h) for the long term estimations.

The maximum chemical life-time in air is calculated similarly by use of the formula:
$\tau = 1 / (k_{OH} \times [OH])$

The ozone rate constant estimations produced by AOPWIN are generally important when one or more functional group is attached to any olefinic or acetylenic unit. It is also important for a limited number of chemical classes (e.g., hydrazines, phenols, alkyl lead compounds, and furans). The database of experimental ozone rate constants is not nearly as extensive as the database for hydroxyl radical rate constants. Because of this smaller available database, the number of fragment values that are available for estimations is considerably smaller. Therefore, the number of compounds that can be estimated with reasonable certainty is smaller. If an "assumed value" is used to produce an estimated rate constant, it is a good idea to check the "Show Calculation" screen for ozone to see if a "default value" was used in the calculation. If a default value was used, consider the estimate questionable.
Ozone reaction half-lives for organic chemicals can also be estimated similar to the approach used with hydroxyl radical by using an average ozone concentration and equation

The half-life in the troposphere, $t½ = \ln 2 / (k_{Ozone} \times [ozone])$

Atkinson & Carter (1984) indicated that [ozone] are around 10-40 ppb (0.25 to 1×10^{-12} molecules/cm^3) at ground level and increases with altitude (30 to 100 ppb at 10 km). These authors used 7×10^{-11} molecules/cm^3 (30 ppb) per 24 hours as representative of an unpolluted lower troposphere and this is

the initial default value for AOPWIN, which was used in the current estimations. As with OH radicals, the concentration of ozone varies with amount of pollution, time of the day, climate, and zonal location.

Results

The overall reaction rate of BYI 02960 with hydroxyl radicals is estimated to be 29.3590 $\times$ 10^{-12} cm^3 $\times$ $molecule^{-1}$ $\times$ s^{-1}. This rate is derived mainly from incremental reactions like hydrogen abstraction (10.7929 $\times$ 10^{-12} cm^3 $\times$ $molecule^{-1}$ $\times$ s^{-1}) and an addition reaction to the C=C bond (18.2490 $\times$ 10^{-12} cm^3 $\times$ $molecule^{-1}$ $\times$ s^{-1}).

Based on the overall hydroxyl radical reaction rate constant in combination with the "short term" concentration of these radicals in the atmosphere during daylight (i.e. 1.5 x 10^6 OH radicals cm^{-3}) the half-life (t1/2) of BYI 02960 in air is derived to be 4.372 hours.

That estimate should be regarded as worst-case assumption as the approach does not consider the contribution of any other reactive species to the overall atmospheric degradation of BYI 02960 (i.e. by ozone; for its contribution refer to Appendix 3 and Appendix 4 of report). It should be noted that the chemical half-life of the active substance can be expected to be shorter when being applied in the early afternoon since the OH radical concentration in the troposphere may increase to 5 x 10^6 radicals cm^{-3} during the day while these values are lower in the early morning or late afternoon.

Conclusions

BYI 02960 is considered to be susceptible to reactions with hydroxyl radicals to contribute significantly to the overall degradation of the substance in the atmosphere. Various parts of the molecule were identified as potential targets for radical reactions. An attack by hydroxyl radicals and ozone should result in the formation of multiple primary radicals. Their formation may be followed by secondary oxidation products that can be eliminated from the atmosphere by wet and/or dry deposition.

In addition, BYI 02960 is susceptible to reactions with ozone, however, that attack and its resulting chemical half-life is considered to be slower by a factor of 2 to 10.

Remarks

The study is acceptable. The RMS considers the endpoint based on the 12 hour OH radical concentration, in line with FOCUSAIR, reliable. The atmospheric half life of BYI 02960 is estimated to be 4.4 hours. BYI 02960 is not considered to have potential for long range transport based on this result.

B.8.8 Predicted environmental concentrations in air (PECa) (Annex IIIA 9.3)

As a consequence of the short half-life in air, no long-range transport of BYI 02960 in the atmosphere is likely to occur nor an accumulation of BYI 02960 in the environmental compartment air. From the low vapor pressure of the substance it is concluded that very low, if any, quantities of BYI 02960 are expected to enter the atmosphere from volatilization of soil residues.

B.8.9 Definition of the residue (Annex IIA 7.3)

Detailed guidance to define the environmental residue is available in SANCO/10329/2002 rev 2. final (Oct 2002) and SANCO/3268/2001 rev 4 final (Oct 2002). All metabolites accounted for >10% in aerobic soil treated with BYI 02960.

The components of the environmental residue are therefore as follows:

Residue definition for risk assessment:

Soil:	BYI 02960, DFA, 6-CNA
Surface Water:	BYI 02960, DFA, 6-CNA, BYI 02960-succinamide, BYI 02960-azabicyclosuccinmaide
Sediment:	BYI 02960, DFA, 6-CNA
Groundwater:	BYI 02960, DFA, 6-CNA
Air:	BYI 02960

Residue definition for monitoring:

Soil:	BYI 02960
Surface Water:	BYI 02960
Groundwater:	BYI 02960
Air:	BYI 02960

B.8.10 References relied on

Literature search

A literature review was conducted for flupyradifurone and its metabolites according to the requirements of Regulation EC 1107/2009. The total number of literature findings within the last ten years before submission were 342, all referring to two metabolites. A large number of keywords, grouped by the categories “health”, “environment” and “non target species” has been used as a text mining filter. From the total of 342 references, 136 publications were identified which gave a matching overlap with one or more of the keywords used. All 342 references were reviewed by scientific experts and categorized.

The filter was merely tested, and improved, as a tool to be applied in future literature reviews for other compounds. From those references which could not be allocated to one of the categories “health”, “environment” or “non target species”, none was identified by the scientific experts to provide relevant information for regulatory purposes, i.e. no false negative findings were identified.

None of the studies was considered relevant as defined by the EFSA Guidance document on ‘submission of scientific peer-reviewed open literature for the approval of pesticide active substances under Regulation (EC) no. 1107/2009’, i.e. as “dealing with side-effects on health, the environment and non-target species”.

In the area of toxicology, only one publication was evaluated as “relevant”. Fortunately this publication was already known and the result was therefore already assessed and fully integrated in the supplementary dossier Therefore, no reference had to be discussed separately in the dossier, as all risk assessments remained fully valid after consideration of all references.

In conclusion, no information was identified which was considered to have an impact on an endpoint or would result in the need to adapt a risk assessment in the flupyradifurone dossier.

The applicant also provided an additional literature search for the two water metabolites. This was a data requirement set by the EFSA during the review. The search did not result in additional scientific literature since these metabolites were closely related to the active substance flupyradifurone.

Remarks RMS

A literature search and review was provided by the applicant. The search has been conducted in line with the EFSA guidance. Of all identified papers (342) the relevant ones (136) have been selected by the applicant in a transparent way using a text mining filter. The applicant provided a general justification for evaluating the relevant papers. As no study-by-study justifications were given the RMS can not properly verify whether the 136 relevant papers were correctly evaluated in terms of reliability/validity/acceptability for regulatory use. The one study that was considered relevant by the

applicant is evaluated in the DAR. RMS notes that flupyradifurone is a new active substance worldwide. Therefore, public literature is not expected to be an important new information source for the active substance itself.

B.9 Ecotoxicology

Introduction

Flupyradifurone (BYI 02960) is a new active substance. It is a xylem mobile insecticide with systemic activity, effective against aphids, leafhoppers, whiteflies, scales and psyllids.

The formulation BYI 02960 SL200 (Sivanto, also called BYI 02960 SL 200 G, BYI 02960 SL 200 g/L and Flupyradifurone SL 200 G) is the representative formulation for the registration of Flupyradifurone (BYI 02960) in Europe, with a nominal content of 200 g a.s./L.
The intended uses of Sivanto, which are being supported for the first inclusion of flupyradifurone in Annex I of the Council Directive 91/414/EEC, are aphid control in hops (field) and in lettuce (field and greenhouse). See table 10-1 for the intended use pattern.

Table 10- 1 Intended use pattern

Crop	F or G*	Timing of application BBCH (months)	Number of applications	Application interval [days]	Maximum label rate [L/ha]	Maximum application rate, individual treatment [g a.s./ha] BYI 02960	Remarks

B.9.1 Effects on birds (IIA 8.1; IIIA 10.1)

B.9.1.1 Acute oral toxicity (IIA 8.1.1)

STUDY IIA, 8.1.1/01

Characteristics of the study

reference	:	[redacted]. (2010)	species	:	Bobwhite quail (*Colinus virginianus*)
type of study	:	Acute oral toxicity study	observations	:	14 days
year of execution	:	2009	dose	:	25, 50, 100, 200 and 400 mg a.s./kg bw
GLP statement	:	Yes	dosing method	:	Gavage in gelatin capsule
guideline	:	OPPTS 850.2100, OECD 223	acceptability	:	Acceptable
test substance	:	BYI 02960; technical, batch BYI 02960-01-03 (origin batch 2009-000239)	LD50	:	232 mg a.s./kg bw
purity	:	96.2%			

Methods

In a study on the acute oral toxicity of BYI 02960 technical to bobwhite quail (*Colinus virginianus*), groups of five males and five females per dose level (14-week-old, fasted overnight) were orally dosed with BYI 02960 technical in gelatin capsules at dose levels of 25, 50, 100, 200 and 400 mg a.s./kg bw, followed by a fourteen day observation period. A control receiving empty gelatin capsules was included.

Results

The number of bird moralities during the study were: control (0), 25 (0), 50 (0), 100 (0), 200 (4), and 400 (9) mg a.s./kg body weight. The acute oral LD50 (Probit analysis) was 232 mg a.s./kg bw (95% CI 173-313 mg a.s./kg bw).

Signs of toxicity (hypo-reactivity) were observed at 100 mg a.s./kg bw (1 bird) and at 200-400 mg a.s./kg bw (4-8 birds).

Male and female body weight was statistically significantly reduced at 200 mg a.s./kg bw on day 7, and the body weight of the single female survivor at 400 mg a.s./kg bw was also reduced on day 7. Male and female body weight gain was statistically significantly reduced at 200 mg a.s./kg bw during day 0-7, and female body weight gain also during day 0-14, whereas body weight gain of the single female survivor at 400 mg a.s./kg bw was reduced on day 0-7 and 0-14.

Feed consumption was not subjected to statistical analysis, but was reduced in a dose-related manner in all treated female groups. Male feed consumption was increased relative to the control in all treated groups.

Necropsy (performed on all birds in the control and at 100-400 mg a.s./kg bw, and on 4 birds in the remaining groups) revealed no treatment-related abnormalities.

Conclusion

Acute oral LD50 for bobwhite quail 232 mg a.s./kg bw.

Guidelines and limitations

The study is acceptable.

STUDY IIA, 8.1.1/02

Characteristics of the study

GLP statement	:	Yes	dosing method	:	Gavage in gelatin capsule
guideline	:	OPPTS 850.2100, OECD 223	acceptability	:	Acceptable
test substance	:	BYI 02960; technical, batch BYI 02960-01-03 (origin batch 2009-000239)	LD50	:	330 mg a.s./kg bw
purity	:	96.2%			

Methods

In a study on the acute oral toxicity of BYI 02960 technical to the canary (*Serinus canaria*), groups of five males and five females per dose level (in adult plumage, fasted overnight) were orally dosed with BYI 02960 technical in gelatin capsules at dose levels of 44, 88, 175, 350 and 700 mg a.s./kg bw, followed by a fourteen day observation period. A control receiving empty gelatin capsules was included.

Results

The number of bird moralities during the study were: control (0), 44 (0), 88 (0), 175 (5), 350 (5), and 700 (7) mg a.s./kg body weight. The acute oral LD50 (Probit analysis) was 330 mg a.s./kg bw (95% CI 215-625 mg a.s./kg bw).

Signs of toxicity (including loss of muscular coordination, lethargy, diminished reaction to stimuli, prostrate, unable to move) were observed at 44-700 mg a.s./kg bw (6-10 birds).

There were no treatment related effects on male and female body weight, body weight gain and feed consumption.

Post-mortem examinations were not performed.

Conclusion

Acute oral LD50 for canary 330 mg a.s./kg bw.

Guidelines and limitations

The study is acceptable.

STUDY IIA, 8.1.1/03

Characteristics of the study

reference	:	[redacted] (2011)	species	:	Hen (*Gallus gallus domesticus*)
type of study	:	Acute oral toxicity study	observations	:	28 days
year of execution	:	2011	dose	:	2000 mg a.s./kg bw
GLP statement	:	Yes	dosing method	:	Gavage in gelatin capsule
guideline	:	OPPTS 850.2100, OECD 223	acceptability	:	**Not acceptable**
test substance	:	BYI 02960 (tech.), batch BYI 02960-01-03 (origin batch 2009-000239)	LD50	:	**Not reliable**
purity	:	96.2%			

Methods

In a study on the acute oral toxicity of BYI 02960 technical to hens (*Gallus domesticus*), five hens (18 weeks old, fasted overnight) were orally dosed with BYI 02960 technical in gelatin capsules at a dose level of 2000 mg a.s./kg bw, followed by a 28-day observation period. A control consisting of 10 hens receiving empty gelatin capsules was included.

Results

No mortalities occurred in the control and the treated group during the 28-day observation period. Due to findings on day 21, the test was prolonged to 28 days. Half of the control birds were sacrificed on day 21. The report described the study findings as follows:

"*The most noticeable effect after the application was an almost complete reduction of food consumption with all dosed birds. All further observed symptoms were consequences of this starvation, e.g. excretion of uric acid, fluffed feather, or reduced vigilance. One bird started to feed in the 2nd week after application, another one in the 3rd week after application. Both birds showed soft excrements or diarrhoea as indication of digestion distress. A third bird behaved similarly in the 4th week after application.*

Two birds dosed did not resume feeding at all after application of the test substance. They were sacrificed for human reasons on day 28. These birds may be considered as treatment related mortalities. Since all other birds were free of symptoms or showed clear indications of recovery by that time point, the test was terminated on day 28.

Due to the reduced food consumption all dosed birds showed severe body weight losses. Two birds started to regain body weight in the last week of the test.

Pathological findings at necropsy: All birds were emaciated."

The two birds humanely killed on day 28 were considered as treatment related mortalities and factored into the LD50 calculation. Based on these findings, the author of the report estimated the LD50 to be >2000 mg a.s./kg bw.

Evaluation by RMS

Results on feed intake and body weight measurements are summarised in the table below. The report did not state which two dosed birds, which did not resume feeding at all after application of the test substance, were sacrificed for humane reasons on day 28. The results in the Table show that feed intake of birds 17, 18 and 19 during day 7-28 was comparable and negligible, and terminal body weights of these 3 birds were equally low, with comparable body weight loss during day 21-28. It is unclear why the author of the report stated that "*One bird started to feed in the 2nd week after application, another one in the 3rd week after application. Both birds showed soft excrements or diarrhoea as indication of digestion distress. A third bird behaved similarly in the 4th week after application.*", since 3 out of 5 birds hardly fed during day 7-28.

Post mortem examination of these 3 birds gave comparable findings (all 3 kidneys reduced and emaciated or strongly emaciated). It is unclear why the author of the report stated that on day 28 "*three birds were free of symptoms or showed clear indications of recovery*", since no clear indications of recovery of feed intake or body weight gain were apparent during the last study week. In the opinion of the RMS, not two but three birds should have been considered as treatment related mortalities and factored into the LD50 calculation. Since a limit test with three mortalities out of 5 tested is not suitable to derive an accurate LD50 value, the conclusion is that the test does not produce a reliable LD50.

Table B.9.1.1-01 Feed intake and body weight measurements in acute oral toxicity study in hen

	feed intake (g/hen/day)						
treatment	day 0	day 1	day 2	day 3-7	day 7-14	day 14-21	day 21-28
control (mean)	107	88	80	79	83	87	97
bird 16	1	0	1	11	4	12	48
bird 17	2	1	1	1	0	3	1
bird 18	2	0	1	13	0	0	4
bird 19	2	1	2	13	2	5	4
bird 20	2	1	1	15	10	27	97
	body weight (g)						
	day -1	day 3	day 7	day 14	day 21	day 28	
control (mean)	1294	1371	1403	1429	1412	1440	
bird 16	1243	1048	1004	907	847	1045	
bird 17	1265	1217	1106	974	835	748	
bird 18	1452	1336	1201	1035	882	731	
bird 19	1366	1135	1089	990	891	781	
bird 20	1170	987	951	862	879	1196	

Conclusion

The test did not produce a reliable LD50.

Guidelines and limitations

Comments were incorporated in the study summary. The study is not acceptable.

STUDY IIIA, 10.1.6/01

Characteristics of the study

reference	:	[redacted] (2012)	species	:	Bobwhite quail (*Colinus virginianus*)
type of study	:	Acute oral toxicity study	observations	:	21 days
year of execution	:	2011	dose	:	250, 500, 1000, 2000 and 4000 mg a.s./kg bw
GLP statement	:	Yes	dosing method	:	Gavage in deionised water
guideline	:	OPPTS 850.2100	acceptability	:	Acceptable
test substance	:	BYI 02960 SL 200, batch 2010-001067	LD50	:	431 mg a.s./kg bw
a.s. content	:	17.1 % w/w			

Methods

In a study on the acute oral toxicity of BYI 02960 SL 200 (17.1% BYI 02960) to bobwhite quail (*Colinus virginianus*), groups of five males and five females per dose level (16-week-old, fasted overnight) were orally dosed with BYI 02960 SL 200 in deionised water at dose levels of 250, 500, 1000, 2000 and 4000 mg a.s./kg bw, followed by a 21-day observation period. A control receiving deionised water only was included.

Results

The number of bird moralities during the study were: control (0), 250 (1), 500 (6), 1000 (10), 2000 (10), and 4000 (10) mg a.s./kg body weight. The acute oral LD50 (Probit analysis) was 431 mg a.s./kg bw (95% CI 320-576 mg a.s./kg bw).

Signs of toxicity (immobility and hypo-reactivity) were observed at 250 mg a.s./kg bw and above. Male body weights were reduced at 500 mg a.s./kg bw on day 7, and female body weight of the single female survivor at 500 mg a.s./kg bw was reduced on day 7, 14 and 21. Feed consumption of the males at 500 mg a.s./kg bw was reduced compared to the control. Necropsy (performed on all surviving birds at the end of the study) revealed no treatment-related abnormalities.

Conclusion

Acute oral LD50 for bobwhite quail 431 mg a.s./kg bw.

Guidelines and limitations

The study is acceptable.

STUDY IIIA, 10.1.6/02

Characteristics of the study

reference	:	[redacted] (2012)	species	:	Hen (*Gallus domesticus*)
type of study	:	Acute oral toxicity study	observations	:	21 days
year of execution	:	2011	dose	:	2000 mg product/kg bw

GLP statement	:	Yes	dosing method	:	Gavage in gelatin capsule
guideline	:	OPPTS 850.2100, OECD 223	acceptability	:	Acceptable
test substance	:	BYI 02960 SL 200, batch 2011-002192	LD50	:	>2000 mg product/kg bw (>342 mg a.s./kg bw)
a.s. content	:	17.1 % w/w			

Methods

In a study on the acute oral toxicity of BYI 02960 SL 200 (17.1% BYI 02960) to hens (*Gallus domesticus*), five hens (18 weeks old, fasted overnight) were orally dosed with BYI 02960 SL 200 in gelatin capsules at a dose level of 2000 mg product/kg bw, followed by a 21-day observation period. A control consisting of 10 hens receiving empty gelatin capsules was included.

Results

No mortalities occurred in the control and the treated group during the 21-day observation period. Signs of intoxiciation in the treated group included sitting, tremor, reduced vigilance, apathy, discoordinated movements, ptosis, excretion of uric acid, diarrhea and soft excrements. At test termination all birds were free of symptoms. Treated birds lost weight between day 0 and 3, but regained weight thereafter. After the treatment, the dosed birds avoided food almost completely. Four of 5 birds started to feed from day 3 onwards, the last bird from day 7 onwards. Afterwards their feed intake was comparable to control birds. Necropsy (performed on 5 birds in the control and all treated birds) revealed no treatment-related abnormalities.

Conclusion

Acute oral LD50 for hen >2000 mg product/kg bw (>342 mg a.s./kg bw).

Guidelines and limitations

The study is acceptable.

B.9.1.2 Dietary toxicity (IIA 8.1.2 & IIA 8.1.3)

STUDY IIA, 8.1.2/01

Characteristics of the study

reference	:	[redacted] (2010)	species	:	Mallard duck (*Anas platyrhynchos*)
type of study	:	Dietary LC50 study	exposure duration	:	5 days
year of execution	:	2009	nominal conc.	:	313, 625, 1250, 2500 and 5000 mg a.s./kg diet
GLP statement	:	Yes	dosing method	:	Test substance in solvent was mixed with diet using corn oil as excipient
guideline	:	OPPTS 850.2200 & OECD 205	acceptability	:	Acceptable
test substance	:	BYI 02960; technical, batch 2009-000239	LC50	:	>4741 mg a.s./kg diet ⇔ >825 mg a.s./kg bw/day
purity	:	96.2%			

Methods

In a study on the dietary toxicity of BYI 02960 technical, five groups of 10-day old mallard ducks of indeterminate sex (10/group) were fed BYI 02960 technical (dissolved in an unspecified solvent, excipient corn oil, max 1% w/w) in the diet at nominal concentrations of 313, 625, 1250, 2500 and 5000 mg a.s./kg diet, respectively, for a period of 5 days followed by a 3-day recovery period. A control group of ten 10-day old ducklings received feed containing the solvent and corn oil only. Samples of test diet were taken from all treatment groups and analysed for accuracy, using a sufficiently validated HPLC/UV method. Homogeneity and freezer and feeder stability were determined for the lowest and the highest test concentration.

Results

The analytically confirmed concentrations were 294, 581, 1175, 2238 and 4741 mg a.s./kg diet, representing 90-95% of the nominal concentrations. Based on day 0-5 mean feed consumption and body weight data, these concentrations corresponded with 66, 129, 272, 459 and 825 mg a.s./kg bw/d. Homogeneity and freezer and feeder stability were confirmed.

No birds died and no signs of toxicity were observed in any group. Body weights and body weight gain were statistically significantly (5% level) reduced at 2238 and 4741 mg a.s./kg diet on day 5, but after a 3-day recovery period a statistically significantly reduction of body weight was only apparent at 4741 mg a.s./kg diet, whilst body weight gain during day 5-8 in all treatment groups was comparable to the control. Feed consumption was not statistically analysed, but was reduced at 2238 and 4741 mg a.s./kg diet on day 5. During day 5-8 feed consumption in all treatment groups was comparable to the control.

Post-mortem examination (performed on all birds in the control and the high dose group, and on 4 birds in the remaining groups) revealed no abnormalities.

The 5-day dietary LC50 was >4741 mg a.s./kg diet, equivalent to >825 mg a.s./kg bw/day.

Conclusion

5-day dietary LC50 >4741 mg a.s./kg diet, equivalent to >825 mg a.s./kg bw/day.

Guidelines and limitations

The study is acceptable.

STUDY IIA, 8.1.2/02

Characteristics of the study

reference	:	[redacted] (2010)	species	:	Bobwhite quail (*Colinus virginianus*)
type of study	:	Dietary LC50 study	exposure duration	:	5 days
year of execution	:	2009	nominal conc.	:	313, 625, 1250, 2500 and 5000 mg a.s./kg diet
GLP statement	:	Yes	dosing method	:	Test substance in solvent was mixed with diet using corn oil as excipient
guideline	:	OPPTS 850.2200 & OECD 205	acceptability	:	Acceptable
test substance	:	BYI 02960; technical, batch 2009-000239	LC50	:	>4876 mg a.s./kg diet ⇔ >470 mg a.s./kg bw/day
purity	:	96.2%			

Methods

In a study on the dietary toxicity of BYI 02960 technical, five groups of 13-day old bobwhite quail (*Colinus virginianus*) of indeterminate sex (10/group) were fed BYI 02960 technical (dissolved in an unspecified solvent, excipient corn oil, max 1% w/w) in the diet at nominal concentrations of 313, 625, 1250, 2500 and 5000 mg a.s./kg diet, respectively, for a period of 5 days followed by a 3-day recovery period. A control group of ten 10-day old quails received feed containing the solvent and corn oil only. Samples of test diet were taken from all treatment groups and analysed for accuracy, using a sufficiently validated HPLC/UV method. Homogeneity and freezer and feeder stability were determined for the lowest and the highest test concentration.

Results

The analytically confirmed concentrations were 278, 607, 1133, 2075 and 4876 mg a.s./kg diet, representing 83-98% of the nominal concentrations. Based on day 0-5 mean feed consumption and body weight data, these concentrations corresponded with 48, 99, 170, 262 and 470 mg a.s./kg bw/d. Homogeneity and freezer and feeder stability were confirmed.

No birds died and signs of toxicity (hyporeactivity, loss of righting reflex, wing drop) were only observed in the highest treatment group. Body weights and body weight gain were statistically significantly (5% level) reduced in the three highest treatment groups on day 5, and after a 3-day recovery period a statistically significantly reduction of body weight was still apparent in the two highest treatment groups, whilst body weight gain during day 5-8 in all treatment groups was comparable to the control. Feed consumption was not statistically analysed, but was reduced in the two highest treatment groups during day 0-4. During day 5-7 feed consumption in all treatment groups was comparable to the control.

Post-mortem examination (performed on all birds in the control and the high dose group, and on 4 birds in the remaining groups) revealed no abnormalities.

The 5-day dietary LC50 was >4876 mg a.s./kg diet, equivalent to >470 mg a.s./kg bw/day.

Conclusion

5-day dietary LC50 >4876 mg a.s./kg diet, equivalent to >470 mg a.s./kg bw/day.

Guidelines and limitations

The study is acceptable.

B.9.1.3 Subchronic and reproductive toxicity (IIA 8.1.4)

STUDY IIA, 8.1.4/01

Characteristics of the study

test substance	:	BYI 02960; technical, batch 2009-000239	NOEC	:	845 mg a.s./kg diet ⇔ 83 mg a.s./kg bw/day
purity	:	96.2%			

Introduction

Following summary and evaluation is the combination of the initial evaluation of the study of Stoughton et al (2012a) by the RMS and a more detailed evaluation provided by the notifier as response to questions posed by RMS. Also figures, tables and statistical evaluation performed by RMS are added to the text.

Description

Reproduction study with the mallard.

Methods. Birds were housed in pairs. 15 pairs were tested per concentration. Adult birds were acclimated for 7 weeks and then exposed to the test substance in the diet for 20 weeks, 8 weeks prior to egg laying and 10 weeks during egg laying and were evaluated for treatment related effects upon bird health and reproduction. Birds were 12 weeks old upon arrival. Test substance was mixed with diet, nominal concentrations 111, 333 and 1000 mg as/kg fd and a control containing an amount of solvent (unknown) equivalent to the amount in the treated diets. Fifteen replicate groups with one male and one female each. Eggs were collected twice a day during working days from the onset of egg production and set weekly for incubation. Table with the study phases is given below.

Table 9.1.3-1. Study phases test with *Anas platyrhynchos*

Study phases
Acclimation – 7 weeks
Pre-photo stimulation with adult exposure to flupyradifurone – 8 weeks
Pre-egg laying (with photo stimulation) period with adult exposure to flupyradifurone –3 weeks
Egg laying with adult exposure to flupyradifurone – approx. 9 weeks
Post-adult termination (final incubation, hatching, and 14-day offspring rearing period) –6 weeks

Observations. Birds were observed daily for mortality, abnormal behaviour and signs of toxicity. Body weight of adults was determined at test initiation, on weeks 3, 5, 7, 9 and at the adult termination. Feed consumption was measured once a week. Reproductive parameters were determined as from week 12, and number of hatchlings and number of 14-day old survivors, body weight of hatchlings and

14-day old survivors were recorded. Hatchlings were observed daily for signs of toxicity, injuries, illness and mortality. Hatchlings were sacrificed by CO_2 asphyxiation at day 14. Gross pathology of adults was conducted at test termination.

Reproductive endpoints.

Following reproductive endpoints were assessed (see Table below).

Table 9.1.3-2. Reproductive endpoints

Endpoints	Description
Adult Body Weight:	The adult body weight change from randomization to adult termination. Analyzed on a per cage basis by sex.
Adult Feed Consumption:	The means were calculated as grams/bird/day. Analyzed on a per cage basis.
Eggs Laid per Hen:	Analyzed as the total egg production. Eggs laid were analyzed on a per hen basis.
Eggs Cracked of Eggs Laid:	Cracked eggs are determined by candling prior to incubation.Cracked eggs were analyzed on a per hen basis.
Eggs Set:	Eggs placed under incubation are “set.” Analyzed as the total number during the dosing phase. Eggs set were analyzed on a per hen basis.
Viable Embryos (mean):	Fertility is determined by candling on the 14th day of incubation. Fertility analyzed as total fertile eggs. Fertility was analyzed on a per hen basis.
Live Embryos (mean):	Live embryos are determined by candling on the 21st day of incubation. Analyzed as the total number of live embryos on a per hen basis.
Eggs Not Cracked of Laid (%):	Eggs laid that were not cracked as a percentage of eggs laid on a per hen basis. Analyzed as the mean percentage during the reproductive phase.
Eggs Set of Laid (%):	Eggs set as a percentage of eggs laid on a per hen basis. Analyzed as the mean percentage during the reproductive phase.
Viable Embryos of Eggs Set (%):	Live embryos as a percentage of eggs set on a per hen basis. Analyzed as the mean percentage during the reproductive phase.
Live Embryos of Viable Embryos (%):	Live embryos as a percentage of viable embryos on a per hen basis. Analyzed as the mean percentage during the reproductive phase.
Number Hatched (mean):	Live hatchlings that had liberated themselves from their eggs by day 28 of incubation. Analyzed as the total number of normal hatchlings on a per hen basis.
14-day-old Survivors (mean):	Live chicks at 14-days post hatch. Analyzed as the total number of 14-day survivors on a per hen basis.
Number Hatched of Eggs Laid (%):	Hatchlings as a percentage of eggs laid on a per hen basis. Analyzed as the mean during the reproductive phase.
Number Hatched of Eggs Set (%):	Hatchlings as a percentage of eggs set on a per hen basis. Analyzed as the mean during the reproductive phase.
Number Hatched of Live Embryos (%):	Hatchlings as a percentage of live embryos on a per hen basis. Analyzed as the mean during the reproductive phase.
14-day-old Survivors of Eggs Set (%):	Live chicks at 14-days post hatch as a percentage of eggs set on a per hen basis. Analyzed as the mean during the reproductive phase.
14-day-old Survivors of Number Hatched (%):	Live chicks at 14-days post hatch as a percentage of hatchlings on a per hen basis. Analyzed as the mean during the reproductive phase.
Hatchling Body Weight:	Individual weights of the live hatchlings taken upon removal from the hatcher, analyzed on a per hen basis. Analyzed as the overall mean during the reproductive phase
14-day-old Survivor Body Weight:	Individual weights of the 14-day-old offspring taken at sacrifice, analyzed on a per hen basis. Analyzed as the overall mean during the reproductive phase.

Eggshell Strength:	The force needed to penetrate the shell and membrane measured at one point on the waist of the egg, analyzed on a per hen basis.
Eggshell Thickness:	The thickness of the shell plus the membrane measured at three points around the waist of the egg, analyzed on a per hen basis

Conditions. housing in pairs, 21.3 °C, 54.7% RH, 7:17 h L:D for the first 15 weeks including acclimation phase. Photoperiod was increased to 17:7 h L:D to induce egg laying (95-250 lux). Eggs were placed in an incubator (36.9°C, 59.8 % RH). On day 23 of in cubation, eggs were place into a hatcher and allowed to hatch (36.8 °C, 69.3 % RH). Hatchlings were placed in a brooding compartment at approx. 32-38°C in 14-d post hatchling phase with 14 h light per day. Feed and water *ad libitum*.

Chemical analysis.

Method validation: Samples were spiked at 10, 100, 500 and 1000 mg/kg fd, extracted and analysed.

Analysis of test diet: Actual concentrations in the diet were determined at week 1, 5, 10, 15 and 20 from samples of 111, 333 and 1000 mg as/kg feed.

Homogeneity of test diet: Samples from test concentrations 111 and 1000 mg/kg fd were taken from the top, middle and bottom of the mixing vessel of samples taken from the first week.

Stability test diet: Samples to verify the stability of the test substance under actual test conditions were taken on day 7 and after a 5-week freezing period, both with samples treated at 111 and 1000 mg/kg fd.

Extraction with acetonitrile/HPLC-grade water (1:1 v/v) by by placing on a magnetic stir plate for stirring during 2 h. Then, the feed was allowed to settle to the bottom of the jar. A 3 mL aliquot of the organic layer was transferred to a centrifuge tube and was rinsed with with acetonitrile/HPLC-grade water. Extracts were analysed by HPLC. Limit of quantitiation was 10 mg/kg fd.

Statistics. The no observed adverse effect concentration (NOAEC) and lowest observed adverse effect concentration (LOAEC) were identified for each parameter (with the exception of adult termination bodyweight) using hypothesis testing methodology. Data from flupyradifurone treatment groups were compared to controls using the Shapiro-Wilk's test for normality and Levene's test of equal variance to determine if dose groups had unequal variances. If assumption of normality ($p \leq 0.01$) and homogeneity of variance ($p \leq 0.05$) were met, then parametric analyses were conducted using analysis of variance (ANOVA) followed by Dunnett's test or William's test. If variances were unequal, then the non-parametric analyses were conducted using the Jonckheere or Mann-Whitney procedures. Statistical analyses were performed at the $\alpha = 0.05$ (95% confidence level). Analysis of adult termination bodyweight data was conducted by subjecting data to a Chi Square Test for normality and a Bartlett's Test for equal variances. The analysis of variance was conducted followed by a Dunnett's Test for unequal replicate size.

Results

Diet analysis

Analytical recovery. Overall mean procedural recovery of fortified samples was 111%, relative standard deviation (RSD) 2%.

Homogeneity*:* The average of the measured concentrations from six 111-ppm homogeneity samples was 108 ppm (97 % of nominal) with a RSD of 13 %. The average of the measured concentrations from six 1000-ppm homogeneity samples was 1001 ppm (100 % of nominal) with a RSD of 8 %.
Concentration verification*:* Freshly prepared feed contained overall average measured concentrations of 91.3, 298, 845 mg/kg fd for the 111, 333 and 1000 mg/kg fd concentrations, respectively (83, 90 and 85% recovery)..
Stability: At day 7 recovery was 78 and 93%, from 100 and 1000 mg/kg fd concentrations, respectively, confirming stability. The recovery from frozen samples averaged 81% for 106 mg/kg fd and 93% for 999 mg/kg fd spiked concentration.
Biological observations
Adult mortality: There were no treatment related mortalities in any of the treatment groups tested. No overt signs of toxicity were noted.
Body weight: No statistically significant differences in body weight (mean weights over the whole study period and termination weight) between the control group and any of the concentrations were found for either males nor females. Results are summarised in the tables below.

Table 9.1.3-3. Weight gain in males and females

Reproduction Study SAS Statistical Output Adult Male Weight Gain (g)				
Nominal Treatment (ppm)	Mean	Std. Dev.	% Reduction	Dunnett's p-value
Control	-4.3	83.3	.	.
111	-4.5	54.5	-4.6	0.747
333	9.5	78.2	318.5	0.905
1000	-21.2	47.8	-389.2	0.460

Reproduction Study SAS Statistical Output Adult Female Weight Gain (g)				
Nominal Treatment (ppm)	Mean	Std. Dev.	% Reduction	Dunnett's p-value
Control	203.1	86.3	.	.
111	236.3	95.6	-16.4	0.973
333	241.3	90.1	-18.8	0.982
1000	208.3	52.1	-2.6	0.808

The daily dietary dose for the study was calculated and presented in the table below.

Table 9.1.3-4. Mallard daily dietary dose of flupyradifurone

Mallard Reproduction Study Daily Dietary Dose					
Measured Dietary Concentration (mg ai/kg feed)	Body Weight At Randomization (kg bw)	Body Weight at Termination (kg bw)	Mean Body Weight (kg bw)	Food Consumption[a] (kg feed/bird/day)	Daily Dietary Dose (mg ai/kg bw/day)
91	1.040	1.156	1.098	0.105	9
298	1.043	1.168	1.106	0.103	28
845	1.017	1.110	1.064	0.105	83

[a]Food Consumption duration was measured for the 22-week treated feed exposure period.

$$\textit{Daily Dietary Dose} = \frac{\textit{(Concentration in Feed) * (Food Consumption)}}{\textit{(Mean Body Weight)}}$$

Where:
Concentration in Feed = measured concentration in mg ai /kg feed
Food Consumption = mean consumption during exposure period in kg feed/bird/day.
Mean Body Weight = average of initiation and termination body weight in kg body weight/bird.

Feed consumption: No treatment related effects on feed consumption were observed. Differences were not significant. Reduction fo feed consumption was -1.5%, 1.1% and -1.0%, for 111, 333 and 1000 mg/kg fd, respectively.

Necropsy results

Necropsy observations of all adult birds subjected to necropsies showed no compound related effects. Concern of RMS was that the post-mortem examination showed that the contents of crop and proventricula gizzard at 1000 ppm were similar to that of the control, while at 111 and 333 ppm crop content seemed to be lower. The number of maturing follicles and eggs in the oviduct was the same in control and 1000 ppm (n = 12 and 5, respectively), but lower at the two other doses (n = 5 and 2)
Response by the notifier: In order to avoid misinterpretation of the post-mortem examination it is important to recognize that the number of necropsied individuals is different in the control and the top dose level (all birds necropsied: 15 males and 15 females at each level), whilst necropsy in the low and mid dose level is limited to only 5 males and 5 females from each dose level (unless triggered by findings at the top dose level). Taking these unequal numbers into account, there are no differences or findings in the post-mortem investigation that could induce concerns at any dose level (see table 9.1.3-6).
Two semi-quantative evaluations were performed by the notifier.
In the first calculation the contents of the crop and proventriculus were each related to the number of females and then combined. The mean numbers were 1.70, 1.50, 1.80 and 1.30 for control, 111, 333 and 1000 mg as/kg fd.
In the second calculation the notifier combined the maturing follicles and the number of eggs in the oviduct and related this number to the number of female birds. Total eggs in production/N were 1.13, 1.40, 1.75 and 1.13 for control, 111, 333 and 1000 mg as/kg fd. According to notifier, there are no

differences of findings in the post-mortem investigation that could induce concerns at any dose level when taking the unequal numbers into account.

Evaluator agrees to this evaluation. It should be remarked that in the study results it was not possible to relate the females in necropsy to a particular pen number. It is assumed that the two outliers were not part of this necropsy.

Table 9.1.3-5 Semi-quantitative evaluation of necropsy results

In the table below a summary is given for all reproductive parameters tested. For none of the parameters, a significant difference with the control was observed. However, some differences at 333 mg/kg fd were close to significance, with p-values close to 0.05. Only these p values were included in the table. The non-breeder in cage 301 of 1000 mg/kg fd was excluded from the analyses. Notifier claimed a lack of a consistent dose response in this study.

Table 9.1.3-6 Summary of reproductive performance from a mallard reproduction study with flupyradifurone. Including data normalized as percentages (%).

Reproductive parameter	Experimental group (mg as/kg fd)			
	Control	111	333	1000
Number of replicates	15	15	15	15
Eggs laid per hen	61.6	56.5	53.7 (p = 0.088)	61.3
Eggs cracked per hen	0.2	0.27	0.33	0.21
Eggs not cracked/eggs laid (%)	99.7	99.3	99.5	99.7
Eggs set per hen	55.9	50.3	47.5 (p = 0.082)	55.4

Eggs set/eggs laid (%)	90.4	88.0	86.5	89.9
Viable embryos per hen	51.5	48.5	42.8 (p = 0.065)	51.4
Viable embryos/eggs set (%)	92.7	96.7	87.3	93.0
Live embryos per hen	51.2	48.0	42.5 (p = 0.066)	51.1
Live embryos/viable embryos (%)	99.5	98.0	99.2	99.3
Hatchlings per hen	47.5	43.3	37.7 (p = 0.051)	46.3

Hatchlings/eggs laid (%)	77.3	75.4	66.9	74.1
Hatchlings/live 3-week embryos (%)	93.0	90.3	88.8	89.4
Hatchlings/eggs set (%)	85.7	85.6	76.0	82.3
Hatchling survival/no. hatched (%)	99.4	99.5	99.7	99.5
Eggshell strength	2.66	2.72	2.55	2.82
Eggshell thickness	0.363	0.355	0.359	0.369

RMS was concerned about the p-values which were close to 0.05 and concluded initially that the NOAEL in this study should be set at 111 mg/kg fd. This was underpinned by the fact that several reproductive parameters reductions between 13 and 21% were present at 333 mg as/kg fd (see Table 9.1.3-6) (an effect percentage of 10% was considered to be the level of unacceptable effects) and that the improved performance at 1000 mg/kg fd could not be explained. Therefore, more information was requested from the notifier and the data were analysed in more detail.

In the table below, the reproductive parameters are presented as percentage difference to the control.

Table 9.1.3-7. Summary of reproductive performance, expressed as % difference from the control, from a mallard reproduction study with flupyradifurone. A negative sign indicates a decrease as compared to the control, a positive sign an increase.

Reproductive parameter	Experimental group (mg as/kg fd)		
	111	333	1000
Eggs laid per hen	-8.2	-12.9	-0.5
Eggs cracked per hen	+33.3	+66.7	+7.1
Eggs not cracked/eggs laid (%)	-0.4	-0.2	-0.0
Eggs set per hen	-9.9	-14.9	-0.9
Eggs set/eggs laid (%)	-2.7	-4.3	-0.5
Viable embryos per hen	-5.7	-16.8	-0.1
Viable embryos/eggs set (%)	+4.3	-5.8	+0.3
Live embryos per hen	-6.3	-17.1	-0.3
Live embryos/viable embryos (%)	-1.5	-0.3	-0.2
Hatchlings per hen	-8.9	-20.5	-2.5

Initial hatchling body weight (g)	-2.8	0.0	-3.7
Survivor hatchling body weight (g)	-0.3	+1.4	-1.2
Hatchlings/eggs laid (%)	-2.4	-13.5	-4.2
Hatchlings/live 3-week embryos (%)	-2.8	-4.5	-3.8

Eggshell strength	-2.08	-4.11	-0.35
Eggshell thickness	-2.06	-0.88	-1.7

In response, notifier performed an additional statistical evaluation whereby excluding another outlier that performed worse than other ducks. This was the bird in cage 213 as it only had 14 eggs laid. The number of eggs laid is considered to be the primary determinant in the determination of the outlier. In the table below the p-values are given from the initial and new analysis for those parameters which had p values close to 0.05 in the initial analysis.

Table 9.1.3-8. Summary of reproductive performance from a mallard reproduction study with flupyradifurone. P= values were obtained after using Dunnett's test.

Reproductive parameter	Experimental group (mg as/kg fd)				
	Control	111	333 Initial analysis	New analysis	1000
Number of replicates	15	15	15		15
Eggs laid per hen	61.6	56.5	53.7 (p = 0.088)	(p = 0.220)	61.3
Eggs set per hen	55.9	50.3	47.5 (p = 0.082)	(p = 0.205)	55.4
Viable embryos per hen	51.5	48.5	42.8 (p = 0.065)	(p = 0.171)	51.4
Live embryos per hen	51.2	48.0	42.5 (p = 0.066)	(p = 0.171)	51.1
Hatchlings per hen	47.5	43.3	37.7 (p = 0.051)	(p = 0.126)	46.3

Recalculation by RMS

GraphPad Prism was used to statistically reanalyze the data. Two normality tests are being employed in GraphPad Prism: D'Agostino & Pearson omnibus normality test (recommended) and Shapiro-Wilk normality test. Tables 9.1.3-8 and 9.1.3-9 show whether the data pass the normality tests according to each of these tests. Calculations were performed for three situations of data treatment:

1 = No outliers removed (a "0" for all parameters in cage 301)
2 = Outlier removed for 1000 mg as/kg fd (cage 301 with 0 eggs)
3 = Outliers removed for 333 and 1000 mg as/kg fd (cage 301 with 0 eggs and cage 213 with 14 eggs.)

Tables 9.1.3-9 and 9.1.3-10 both show that the data for the three parameters eggs laid, viable embryos/hen and hatchlings per hen, all have a normal distribution at 333 mg as/kg fd according to the recommended D'Agostino & Pearson omnibus normality test and according to Shapiro-Wilk's test that has been used by the notifier.

As the concentration level of 333 mg as/kg fd is under consideration, evaluator concludes that the use of a parametric test when considering cages 301 and 213 as being outliers is justified.

Table 9.1.3-9. Passing normality test (D'Agostino & Pearson omnibus normality test)

	control			111 mg as/kg fd			333 mg as/kg fd			1000 mg as/kg fd		
	1	2	3	1	2	3	1	2	3	1	2	3
Eggs laid per hen	y	y	y	y	y	y	n	n	y	n	y	y
Viable embryos per hen	y	y	y	n	n	n	n	n	y	n	y	y
Hatchlings per hen	y	y	y	y	y	y	y	y	y	y	y	y

1 = No outliers removed (a "0" for all parameters in cage 301)

2 = Outlier removed for 1000 mg as/kg fd (cage 301 with 0 eggs)

3 = Outliers removed for 333 and 1000 mg as/kg fd (cage 301 with 0 eggs and cage 213 with 14 eggs)

Table 9.1.3-10. Passing normality test (Shapiro-Wilk's normality test)

	control			111 mg as/kg fd			333 mg as/kg fd			1000 mg as/kg fd		
	1	2	3	1	2	3	1	2	3	1	2	3
Eggs laid per hen	y	y	y	y	y	y	y	y	y	n	y	y
Viable embryos per hen	y	y	y	y	y	y	n	y	y	y	y	y
Hatchlings per hen	y	y	y	y	y	y	y	y	y	y	y	y

1 = No outliers removed (a "0" for all parameters in cage 301)

2 = Outlier removed for 1000 mg as/kg fd (cage 301 with 0 eggs)

3 = Outliers removed for 333 and 1000 mg as/kg fd (cage 301 with 0 eggs and cage 213 with 14 eggs)

The results show that at 333 mg/kg feed no significant effects are found for the three analysed parameters when the two outliers are removed. As these three parameters had p-values closest to 0.05, it is not considered necessary to reanalyze other parameters (eggs set per hen and live embryos per hen) as well.

To confirm whether 14 eggs produced by the bird in cage 213 exposed to 333 mg/kg fd can indeed be considered to be an outlier, evaluator has further analysed the data by preparing six figures. In these figures all birds were included; also the assumed outlier of 14 eggs at 333 mg as/kg fd.and the outlier of 0 eggs at the highest concentration. Data of the control derived from the concurrent control.

1) number of eggs vs treatment
2) consumption vs eggs
3) weight t=0 vs eggs
4) weight gain vs eggs
5) weight gain vs consumption
6) consumption vs treatment

In Figure 9.1.3-11 three data points, one at each concentration (111, 333 and 1000 mg as/kg fd), fall out of the range of the other data.

Figure 9.1.3-11. Relation treatment and number of eggs laid

Figure 9.1.3-12 shows that the birds with 0 and 14 eggs are on the lower range of feed consumption as compared with other animals in their group. The bird with 26 eggs (111 mg as/kg fd) did not consume much either, but still is within the range of other birds. Another bird ate just as much but produces 45 eggs. The bird with 14 eggs shows a similar feed consumption as the bird in the 1000 mg as/kg fd batch that produces 62 eggs. It is unclear whether there is an effect of the toxicant or that the three birds did not feel well irrespective of the toxicant and therefore did not eat much and also did not produce eggs. There seems to be a dose related effect but on the other hand, it could have been a coincidence that the most mal-performing bird was allotted to the highest dose.

Figure 9.1.3-12. Relation feed consumption and number of eggs laid

From Figure 9.1.3-13 it appears that there is no obvious relation between number of eggs and weight at t=0.

Figure 9.1.3-13. Relation start weight and number of eggs laid

A relationship with weight gain is also absent, as shown in Figure 9.1.3-14. One control bird has only gained 22 g but produced 57 eggs. The birds with 0 and 14 eggs are in the middle of the range of measured weight gains (278 and 244 g gain).

Figure 9.1.3-14. Relation weight gain and number of eggs laid

Figure 9.1.3-15 shows that the birds with 0, 14 and 26 eggs (at 1000, 333 and 111 mg as/kg fd, respectively) are situated at the far left of the figure. The weight gain was related with increasing concentrations (167, 244, 278 g at 111, 333 and 1000 mg as/kg fd) but inversely related with food consumption (91, 75, 67 g at 111, 333 and 1000 mg as/kg fd; see Figure 9.1.3-12). This means that the bird that was eating less (1000 mg as/kg fd batch) had most weight gain. This may be explained by the fact that this bird had not lost weight by laying eggs. On the whole, this bird therefore had most weight gain.

Figure 9.1.3-15. Relation feed consumption and body weight gain

Figure 9.1.3-16 shows an increase in the variation in feed consumption between birds of the 1000 mg as/kg fd batch as compared to the lower levels and the control. It is not clear whether increased consumption by some birds was actually caused by increased spillage of feed as the feed might have been unpalatable. This figure indicates that there might be an effect on consumption of the active substance at the highest concentration.

Figure 9.1.3-16. Relation treatment and consumption

It can be concluded from Figures 9.1.3-11 to 9.1.3-16 that although there seems to be a dose related effect, it is probably a coincidence that the most mal-performing bird was allotted to the highest dose. It is unclear whether there is a real effect of the toxicant. Evaluator assumes that the two birds did not feel well irrespective of the toxicant and therefore did not eat much and also did not produce many eggs.

The author concluded that the NOAEL for both parental and reproduction endpoints of mallard ducks exposed to flupyradifurone over a 20-week reproduction study was 845 mg as/kg fd or 81 mg as/kg bw/d, based on actual measured concentrations.

Remarks by RMS (additional to those already incorporated in above text)

The study was conducted in line with current OECD guidelines. A question was posed by RMS whether notifier could explain the improved performance at 1000 mg/kg fd as compared to the lower doses. A reduced uptake due to e.g. repellency could not be the explanation, since consumption at this level was equal to or slightly higher than at the other dose levels. The analysis of diet also ruled out a mistake in diet preparation. This question was indirectly answered by notifier by removing an outlier at the 333 mg/kg fd level. The outcome removed the impression of a partial dose response. Thus, the impression of an improved performance at the highest level was removed.

Statistical evaluations were performed by RMS to confirm the use of a parametric test. These showed that data indeed have a normal distribution after removal of two outliers from the dataset (cage 301 and cage 213 at 1000 and 333 mg as/kg fd, respectively). When data have a normal distribution, a parametric test such as Dunnett's test can be used after ANOVA. Recalculations by RMS did not show significant effects in any of the parameters as was also demonstrated by the notifier.

Subsequently, figures were prepared by RMS in order to evaluate whether or not the two outliers were acceptable. It can be concluded that it is justified to remove data of the birds from cages 213 (333 mg/kg fd, 14 eggs) and 301 (1000 mg/kg fd, 0 eggs) from the dataset. There are no convincing reasons that could tell the opposite. These two mal performing birds are possibly birds that do not feel well enough. The observed dose related effect, as is clearly observed in Figures 9.1.3-11 to 9.13.-14, is most likely coincidental. The NOEC can therefore be set at a nominal concentrations of 1000 mg as/kg fd. This is equivalent to a mean measured concentration of 845 mg as/kg fd or daily dietary dose of 83 mg as/kg bw/day.

Description

Reproduction study with the bobwhite quail.

Methods. Adult birds (14 weeks old upon arrival from a commercial provider and from the same hatch) were acclimated for 4 weeks and then exposed to the test substance in the diet for 23 weeks, 13 weeks prior to egg laying and 10 weeks during egg laying and were evaluated for treatment related effects upon bird health and reproduction. Birds were 18 weeks old at test initiation, male body weights ranged from 195 to 202 g, female body weights was 199 g. Test substance was prepared by mixing the test substance into a premix that was rmixed with diet, test substance was dissolved using acetone. Diet was prepared on a weekly basis. Nominal concentrations 111, 333 and 1000 mg as/kg fd and a control containing an amount of solvent (acetone) and vehicle (corn oil) equivalent to the amount in the treated diets. Eighteen pair per treatment with one male and one female each per cage. Eggs were collected twice daily on weekdays and once on weekends from the onset of egg production and set weekly for incubation. First eggs were set during week 13. Table with the study phases is given below.

Table 9.1.3-7. Study phases test with *Colinus virginianus*

Study phases
Acclimation – 4 weeks
Photo stimulation with adult exposure to flupyradifurone – 8 weeks
First egg set with adult exposure to flupyradifurone- 13 weeks
Hatchlong phase started on day 21 of incubation of the eggs
Adult termination- 23 weeks
Biological termination- 28 weeks.

Observations. Birds were observed daily for mortality, abnormal behaviour and signs of toxicity. Body weight of adults was determined the day prior to experimental start, on weeks 3, 5, 7, and 9 and at the adult termination. Feed consumption was measured once a week. Reproductive parameters: embryo viability was determined on day's 11, 12, of incubation of the eggs and on day's 18 or 19 to determine embryo survival. One egg was collected from each cage and eggshell strength and thickness was determined. Number of hatchlings and number of 14-day old survivors, body weight of hatchlings and 14-day old survivors were recorded. Hatchlings were observed daily for signs of toxicity, injuries, illness and mortality. Hatchlings were sacrificed by CO_2 asphyxiation at day 14. Gross pathology of adults was conducted at test termination.

Reproductive endpoints.

Following reproductive endpoints were assessed (see Table below).

Table 9.1.3-8. Reproductive endpoints

Endpoints	Description
Adult Body Weight:	The adult body weight change from randomization to adult termination. Analyzed on a

	per cage basis by sex.
Adult Feed Consumption:	The means were calculated as grams/bird/day. Analyzed on a per cage basis.
Eggs Laid per Hen:	Analyzed as the total egg production. Eggs laid were analyzed on a per hen basis.
Eggs Cracked of Eggs Laid:	Cracked eggs are determined by candling prior to incubation.Cracked eggs were analyzed on a per hen basis.
Eggs Set:	Eggs placed under incubation are "set." Analyzed as the total number during the dosing phase. Eggs set were analyzed on a per hen basis.
Viable Embryos (mean):	Fertility is determined by candling on the 11th or 12th day of incubation. Fertility analyzed as total fertile eggs.
Live Embryos (mean):	Live embryos are determined by candling on the 19th day of incubation.
Eggs Not Cracked of Laid (%):	Eggs laid that were not cracked as a percentage of eggs laid on a per hen basis. Analyzed as the mean percentage during the reproductive phase.
Eggs Set of Laid (%):	Eggs set as a percentage of eggs laid on a per hen basis. Analyzed as the mean percentage during the reproductive phase.
Viable Embryos of Eggs Set (%):	Live embryos as a percentage of eggs set on a per hen basis. Analyzed as the mean percentage during the reproductive phase.
Live Embryos of Viable Embryos (%):	Live embryos as a percentage of viable embryos on a per hen basis. Analyzed as the mean percentage during the reproductive phase.
Number Hatched (mean):	Live hatchlings that had liberated themselves from their eggs by day 25 of incubation. Analyzed as the total number of normal hatchlings on a per hen basis.
14-day-old Survivors (mean):	Live chicks at 14-days post hatch. Analyzed as the total number of 14-day survivors on a per hen basis.
Number Hatched of Eggs Laid (%):	Hatchlings as a percentage of eggs laid on a per hen basis. Analyzed as the mean during the reproductive phase.
Number Hatched of Eggs Set (%):	Hatchlings as a percentage of eggs set on a per hen basis. Analyzed as the mean during the reproductive phase.
Number Hatched of Live Embryos (%):	Hatchlings as a percentage of live embryos on a per hen basis. Analyzed as the mean during the reproductive phase.
14-day-old Survivors of Eggs Set (%):	Live chicks at 14-days post hatch as a percentage of eggs set on a per hen basis. Analyzed as the mean during the reproductive phase.
14-day-old Survivors of Number Hatched (%):	Live chicks at 14-days post hatch as a percentage of hatchlings on a per hen basis. Analyzed as the mean during the reproductive phase.
Hatchling Body Weight:	Individual weights of the live hatchlings taken upon removal from the hatcher, analyzed on a per hen basis. Analyzed as the overall mean during the reproductive phase
14-day-old Survivor Body Weight:	Individual weights of the 14-day-old offspring taken at sacrifice, analyzed on a per hen basis. Analyzed as the overall mean during the reproductive phase.
Eggshell Strength:	The force needed to penetrate the shell and membrane measured at one point on the waist of the egg, analyzed on a per hen basis.
Eggshell Thickness:	The thickness of the shell plus the membrane measured at three points around the waist of the egg, analyzed on a per hen basis

Conditions. Housing in pairs, 21.3 °C, 55.3% RH, 7:17 h L:D for the first 8 weeks including acclimation phase. Photoperiod was increased to 17:7 h L:D to induce egg laying (64-194 lux). Eggs were placed in an incubator (37.0°C, 58.9 % RH). On day 21 of incubation, eggs were place into a hatcher and allowed to hatch (36.8 °C, 69.3 % RH). Hatchlings were placed in a brooding compartment at approx. 32 - 38°C and 57.5% RH in a 14-d post hatchling phase with 14 h light per day. Feed and water *ad libitum*.

Chemical analysis.

Method validation: Samples were spiked at 10.1, 101, 504 and 1007 mg/kg fd, extracted and analysed.

Analysis of test diet: Actual concentrations in the diet were determined at week 1, 5, 10, 15 and 20 from samples of 111, 333 and 1000 mg as/kg feed.

Homogeneity of test diet: Samples from test concentrations 111 and 1000 mg/kg fd were taken from the top, middle and bottom of the mixing vessel following the initial feed mixing procedure..

Stability test diet: Samples to verify the stability of the test substance under actual test conditions were taken on day 7 of the freezing period, both with samples treated at 111 and 1000 mg/kg fd.

Extraction with acetonitrile/HPLC-grade water (1:1 v/v) and a stir bar for stirring, capped and placed into a microwave extractor two times during 30 seconds and 5.5 minutes at 50 ºC. Then, the feed was sonicated for 15 minutes in a water bath, filtered and dilutied when needed using acetonitrile/HPLC-grade water (1 : 1 v/v). Extracts were analysed by HPLC-UV/VIS detection at 260 nm. Limit of quantitation was 10 mg/kg.

Statistics. The no observed adverse effect concentration (NOAEC) and lowest observed adverse effect concentration (LOAEC) was identified for each parameter using hypothesis testing methodology. Data from treatment groups were compared to controls using the Shapiro-Wilk's test for normality and Levene's test of equal variance to determine if dose groups had unequal variances. If assumption of normality ($p \leq 0.01$) and homogeneity of variance ($p \leq 0.05$) were met, then parametric analyses were conducted using analysis of variance (ANOVA) followed by Dunnett's test or William's test. If variances were unequal, then the non-parametric analyses were conducted using the Jonckheere or Mann-Whitney procedures. Statistical analyses were performed using SAS program at the $\alpha = 0.05$ (95% confidence level).

Results

Diet analysis

Analytical recovery. Overall mean procedural recovery of fortified samples was 99%.

Homogeneity: The average of the measured concentrations from the 111-mg/kg homogeneity samples was 97.1 mg/kg (week 1l) with a RSD of 10 %, 112 mg/kg with 8% RSD (week 10), and 99.3 mg/kg with 3% RSD (week 20) . The average of the measured concentrations from the 1000 mg/kg homogeneity samples was 855 mg/kg with 8% RSD (week 1), 977 mg/kg with 9% RSD (week 10), and 997 with 9% RSD (week 20).

Concentration verification: Freshly prepared feed contained a mean measured concentrations of 107, 302, and 999 mg/kg fd for the 111, 333 and 1000 mg/kg fd concentrations, respectively (96, 91 and 100% of nominal).

Stability: At day 7 recovery was 114 and 106%, from 100 and 1000 mg/kg fd concentrations compared to the week 1 analysis, respectively, confirming stability. The recovery from the 8 weeks frozen samples averaged 80% for 111 mg/kg fd and 108% for 1000 mg/kg fd compared to the week 1 analysis.

Biological observations

Adult mortality: Nine birds died during the study: two birds in the control group (1 m, 1f), one bird in the 111 mg as/kg group (1 m) and six in the 1000 mg as/kg group (1 m, 5 f). No mortalities in the 333 mg /kg fd group. Treatment related effects were observed in the 1000 mg/kg dose group at necropsy. Four females were observed as being emaciated and all five females had regressed ovaries, no maturing follicles or reduced egg-laying. These results are in agreement with necropsy of surviving birds in the 1000 mg/kg level.

Clinical observations: No overt signs of intoxication were observed during the study or acclimatisation period in any adult test group.

Body weight: A statistically significant difference at the 333 mg/kg dose group as compared to the control was found for the adult male weight gain (reduction of 68.73%). A statistically significant difference at the 1000 mg/kg dose group as compared to control was found for the female weight gain (reduction of 69.43%).

Adult bird feed consumption (g bird/day): No statistically significant differences at any treatment level as compared to the control.

In the table below a summary is given for all reproductive parameters tested.

Table 9.1.3-9 . Summary of reproductive performance from a quail reproduction study with flupyradifurone, technical. Including data normalized as percentages (%).

Reproductive parameter	Experimental group (mg as/kg fd)			
	Control	111	333	1000

Eggshell strength	+7.85	-5.82	-5.71
Eggshell thickness (mm)	+5.43	+2.46	+4.06

*Statistically significant difference between treatment and control group

The author concluded that the NOAEL for both parental toxicity and reproduction endpoints of the bobwhite quail exposed to flupyradifuronetechnical over a 23 week period was nominal 333 mg/kg feed, equivalent to a measured concentration of 302 mg as/kg feed or mean dose of 40 mg as/kg bw/day. The NOAEL was based on statistically and biologically significant parameters.

Remarks by RMS

Validity criteria were met. The study was conducted in line with current OECD guidelines. No significant deviations from the guidelines were noted. At 1000 mg/kg fd, several reproductive parameters showed a statistically significant reduction as compared to the control. Some significant differences were also noted at 333 mg/kg feed. At that dose level there does not seem to be a consistent effect on reproduction. The study author classified some significant differences as not being biologically relevant, but an explanation for this is not given in the study report. When asked, the notifier explained the statement. They say that at the 333 mg as/kg feed concentrations several reproduction parameters even performed better than the control. According to notifier the statistical significance in the % hatchlings of 3-w embryos is merely due to the lower fertility rate in the control. Evaluator agrees that some endpoints are secondary endpoints as they rely on the outcome of more important initial parameters. This specifically accounts for eggs not cracked/eggs laid. Notifier argues that the statistical significance in the parameter hatchling/live 3-week embryos is a secondary or incidental consequence of the lower fertility rate in the control. The lower fertility rate in the control is indeed visible in the primary parameter “eggs laid per hen” (55.6 in the control vs. 60.8 in the 333 mg as/kg fd treatment) and “viable embryos per hen” (44.8 in the control vs. 49.3 in the 333 mg as/kg fd treatment). The parameter “hatchling/live 3-week embryos” has a lower score for the 333 mg as/kg fd than in the control. However, this calculation stands on its own. In principle a 100% score could be reached if all live 3-week embryos lead to the hatchling stage, irrespective of any other primary parameter. It appears that there is a clear dose-related effect: 95.9, 94, 91.9, 88.2% at increasing concentrations. It is common practice to acknowledge that significant differences at a certain concentration lead to a NOEC in the lower concentrations. In this particular case, there is no reason to argue that this effect could be inconsistent, incidental or not meaningful. This would deny the usefulness of any statistical evaluation. Therefore, based on the reproduction parameter “hatchling/live 3-week embryos”, the NOAEL is set to 111 mg/kg feed, equivalent to a measured concentration of 107 mg as/kg feed or daily dietary dose of 14 mg as/kg bw/day (data taken from the report).

B.9.1.4 Summary

Acute, short-term and (sub-)chronic dietary toxicity data

Toxicity studies with BYI 02960 (flupyradifurone) were performed with Bobwhite quail (*Colinus virginianus*), canary (*Serinus canaria*) and mallard duck (*Anas platyrhynchos*). The acute oral toxicity of the formulated product was determined in studies on Bobwhite quail (*Colinus virginianus*) and in Chicken (*Gallus gallus domesticus*). There is no indication that the formulation is more toxic than expected based on the active substance content.

Endpoint selection was done according to the recommendations of the Guidance Document on Risk Assessment for Birds & Mammals, EFSA 2009[1]:

Acute risk assessment: where acute tests for more than one species are available the geometric mean may be used for the refined assessment, except when the endpoint for the most sensitive species is more than a factor 10 below the geometric mean of all the tested species. For BYI 02960, in a worst-case approach the lowest LD50 of 232 mg/kg bw is used for Tier 1 acute risk assessment.

Short-term risk assessment; According to the risk assessment scheme a short-term risk assessment is not required. However, the endpoint from short-term dietary studies, e.g. 5-day dietary study in birds (OECD 205) should be used in an acute risk assessment when indicating a higher toxicity via the dietary exposure route (lower LDD50). In the case of BYI 02960 there is no indication that 5-day exposure via dietary route would provoke higher toxicity than one application via gavage in acute study and therefore the short-term toxicity is not considered in the acute risk assessment.

Reproductive risk assessment: The acute oral LD50 value used in the acute avian assessment should be divided by 10 for comparison with the lowest NOAED from the reproduction study (studies) ignoring purely parental effects (e.g. changes in parental body weight and food consumption). The lower of the values should be used in the tier 1 risk assessment.

For BYI 02960 the endpoint from the reproduction study (14 mg/kg bw/d) is lower than the 1/10th of the LD50 of 232 mg/kg bw that has been proposed for use in the Tier 1 acute risk assessment.

Therefore, the endpoint of 14 mg/kg bw will be used in a Tier 1 reproductive risk assessment for birds.

An overview of accepted toxicity data for a.s. and formulation is given in Table B.9.1.4-01. Endpoints selected for first tier risk assessment are marked **bold.**

Table B.9.1.4-01 Overview of accepted toxicity data for BYI 02960 and BYI 02960 SL 200

Study	Substance	Species	Route	Criterion	Value [mg/kg fd]	Value [mg a.s./kg bw·d]

Risk to birds of metabolites of BYI 02960

In the residue section of the DAR, metabolites DFA and DFEAF are considered relevant:

Plants

Residue definition for monitoring:

Results from supervised residue trials show that flupyradifurone and difluoroacitic acid (DFA) are, by far, the most prominent components of the residues in target plants and rotational crops. The residues of metabolite difluoroethyl-amino-furanone (DFEAF) were below the LOQ of 0.01 mg/kg in virtually all samples. Considering these results as well as those from the metabolism studies, the proposed residue definition for monitoring for target plants and rotational crops is:

The sum of parent compound and DFA, expressed in flupyradifurone equivalents.

Residue definition risk assessment:

For flupyradifurone residues in target plants (primary crops) and rotational crops (succeeding crops), the proposed residue definition for data collection and risk assessment is:

The sum of parent compound flupyradifurone and its metabolites DFA and difluoroethyl-amino-furanone (DFEAF), expressed in flupyradifurone equivalents. A conversion factor is not required to cover the difference between the residue definition for monitoring and risk assessment as bith DFA and flupyradifurone are part of the residue definition for monitoring and as DFEAF is found in levels below <0.01 mg/kg in supervised residue trials and in rotational crops.

In the human toxicology risk assessment, the following is concluded:

Toxicologically relevant compounds (animals and plants)	Parent compound, DFA
Toxicologically relevant compounds (environment)	Parent compound, DFA

Based on the above, metabolite DFA is considered to be relevant for the terrestrial vertebrate risk assessment.

No avian toxicity study is conducted with DFA but mammalian toxicity data suggest no higher toxicity of the metabolite than from the parent.

Furthermore, the residue data from trials in lettuce and cereals (as surrogate for ground vegetation in hops) demonstrate little difference in the decline DT50 whether or not DFA is included in the residue concentrations (see B.9.3). The trials indicate mostly faster dissipation on foliage than the default DT50 of 10 days.

The first tier risk assessment is therefore based on initial maximum concentrations of the a.s. and the generic DT50 of 10d and this is considered to cover metabolite DFA.

B.9.1.5 Risk assessment for birds (IIIA 10.1)

Risk assessment

The risk assessment procedure follows the EFSA Guidance Document on Risk Assessment for Birds & Mammals (2009).

At Tier 1, the risk is considered acceptable, if the 'Toxicity Exposure Ratio' (TER) value pass the trigger values of ≥ 10 for acute exposure and ≥ 5 for chronic exposure.

If the TER values are below these a-priori acceptability trigger values in certain areas, a refined risk assessment based on more relevant and realistic conditions is performed for those particular areas.

Routes of exposure

The formulation is to be sprayed on hops in the field and on lettuce in glasshouses and in the field.

The following routes are considered:

- direct dietary exposure: scenarios for hop and leafy vegetables – field uses only
- direct exposure via drinking water: field and glasshouse uses
- indirect exposure by consumption of earthworms and fish containing residues of BYI 02960 field and glasshouse uses

B.9.1.5.1 Exposure via feed

Calculation of Toxicity Exposure Ratio (TER)

According to the EFSA Guidance Document on Risk Assessment for Birds & Mammals (2009), the calculation of acute and long-term Toxicity to Exposure Ratio (TER) is defined as follows:

Acute risk: TERa = LD50 [mg as/kg bw] / DDDac

Long-term risk: TERlt = [lowest of NOEL and LD50/10] [mg as/kg bw] / DDDmean

Calculation of Daily Dietary Dose (DDD)

Acute exposure DDDac:

The daily dietary dose for a single application per crop is given by the following equation:

DDDACac = application rate [kg/ha] × shortcut value (SV90)

Long-term exposure DDDmean:

For a single application the daily dietary dose is given by the following equation:

DDDmean = application rate [kg/ha] × shortcut value (SVm) × fTWA

Where

DDD Daily dietary dose

fTWA Time weighted average factor ftwa based on a default time window of 21 days and a DT50 of 10 days leading to a value of 0.53

90 90th percentile values for acute exposure

m mean values for reproductive/long-term exposure

Standard exposure scenario for Tier 1 risk assessment

The main potential exposure route for birds is expected to be consumption of contaminated feed. This is only relevant for field uses.

The Tier 1 risk assessment is based on generic focal species associated with specific crop scenarios. Default ("shortcut"-) values for the exposure estimate will be used as provided in Appendix A of the EFSA Guidance Document on Risk Assessment for Birds & Mammals (2009) representing a worst case assessment.

In the Tier 1 risk assessment it is assumed that

- animals satisfy their entire food demand in the treated area (PT = 1),
- over an acute time frame (hours) the animals feed on items containing maximum residues (90th percentile), whereas they would ingest food containing mean residues over a long-term period (days to weeks),
- long-term predicted environmental concentrations to be compared with chronic endpoints can be calculated as the time-weighted average concentration. Default assumptions are a time window of 21 days and a DT50 of 10 days leading to a time weighted average factor (= ftwa) of 0.53. This factor is equally valid for feed items consisting of vegetation and for arthropods.

Avian generic focal species for Tier 1 risk assessment

In the field, the product is intended to be used in hops at BBCH 31-75 and in lettuce at BBCH 12-49. According to the EFSA Guidance Document on Risk Assessment for Birds & Mammals (2009) the following generic focal species are addressed in Tier 1 risk assessment.

Table B.9.1.5.1-01: Relevant generic avian focal species for Tier 1 risk assessment

Crop	Growth stage (BBCH)	Generic focal species	Representative species	Shortcut value	
				For long-term RA based on RUD_m	For acute RA based on RUD_{90}
Hops	≥ 20	Small insectivorous bird "finch"	Chaffinch	**10.6**	**25.3**
	20-39	Small granivorous bird "finch"	Goldfinch	**5.7**	**12.3**
	≥ 40	Small granivorous bird "finch"	Goldfinch	3.4	7.4
Lettuce (Leafy vegetables)	10-19	Medium herbivorous/granivorous bird "pigeon"	Wood pigeon	**22.7**[1]	**55.5**[1]
	10-49	Small granivorous bird "finch"	Serin	**12.6**	**27.4**
	10-49	Small omnivorous bird “lark”	Woodlark	**10.9**	**24.0**
	10-19	Small insectivorous bird “wagtail”	Yellow wagtail	**11.3**	**26.8**
	≥ 20	Small insectivorous bird “wagtail”	Yellow wagtail	9.7	25.2

Bold values were used for Tier 1 risk assessment. Where the same focal species is representative for different BBCH stages, only the worst-case SV values were chosen for the Tier 1 risk assessment.

[1] The long-term and acute SV-values for this scenario reported in the EFSA GD are 37.0 and 90.6, respectively. However, these were mistakenly based on a FIR/bw of 1.29 (calculated for a passerine species) instead of 0.79 (for non-passerine species, which is correct for the pigeon). The corrected values are in line with those reported for the “pigeon” in early stages of legume forage, maize and oilseed rape.

Tier 1 acute toxicity exposure ratio for birds

Table B.9.1.5.1-02: Tier 1 acute DDD and TER calculation for birds

Crop (BBCH)	Generic focal species	LD50 [mg/kg bw]	DDD			DDD	TERA	Trigger
			Appl. rate [kg/ha]	SV90	MAF90			
BYI 02960								
Hops (≥ 20)	Small insectivorous bird "finch"	232	0.150	25.3	1	3.80	61	10
Hops (20-39)	Small granivorous bird "finch"			12.3		1.85	126	
Lettuce (10-19)	Medium herbiv./ granivorous bird “pigeon”	232	0.125	55.5	1	6.94	33	10
Lettuce (10-49)	Small granivorous bird “finch”			27.4		3.43	68	
Lettuce (10-49)	Small omnivorous bird “lark”			24.0		3.0	77	
Lettuce (10-19)	Small insectivorous bird “ wagtail”			26.8		3.35	69	

The TER values for both crops are above the trigger of 10 for acute exposure. Hence, no unacceptable acute risk to birds from the use of the product according to the intended use pattern is to be expected.

Tier 1 long-term toxicity exposure ratio for birds

Table B.9.1.5.1-03: Tier 1 long-term DDD and TER calculation for birds

Crop (BBCH)	Generic focal species	NO(A)EL [mg/kg bw/d]	DDD				DDD	TERLT	Trigger
			Appl. rate [kg/ha]	SVm	MAFm	fTWA			
BYI 02960									
Hops (≥ 20)	Small insectivorous bird "finch"	14	0.150	10.6	1.0	0.53	0.84	16.6	5
Hops (20-39)	Small granivorous bird "finch"			5.7			0.45	31.9	
Lettuce (10-19)	Medium herbiv./graniv. bird “pigeon”	14	0.125	22.7	1.0	0.53	1.50	9.3	5
Lettuce (10-49)	Small granivorous bird “finch”			12.6			0.83	16.8	
Lettuce (10-49)	Small omnivorous bird “lark”			10.9			0.72	19.4	
Lettuce (10-19)	Small insectivorous bird “ wagtail”			11.3			0.75	18.7	

The TER values for both crops are above the trigger of 5 for long-term exposure. It is noted that targeted residue decline data are available in the section on wild mammal risk assessment, which indicate that the TER values for (partly) herbivorous birds are even underestimated.
Hence, no unacceptable risk to birds from the use of the product according to the intended use pattern in lettuce and hops is to be expected.

B.9.1.5.2 Exposure via drinking water

An assessment of the risk potentially posed by consumption of contaminated drinking water is required according to the EFSA Guidance Document for Birds and Mammals (2009).
Two scenarios were identified as relevant for assessing the risk of pesticides via drinking water to birds and mammals:

- Leaf scenario, only relevant for birds possibly drinking water from puddles in leaf whorls after application of a pesticide to a crop and subsequent rainfall or irrigation. This scenario is only relevant for acute exposure and only for certain crop types. When the product is applied in hops, the formation of pools in leaf axils where an acute exposure possibly might occur can be

excluded. However, for lettuce, the risk of birds drinking from puddles in leaf whorls cannot be excluded. Hence, a corresponding risk assessment has been performed below.

- Puddle scenario. Birds and mammals taking water from puddles formed on the soil surface of a field when a (heavy) rainfall event follows the application of a pesticide to a crop or bare soil. This scenario is relevant for all types of applications that may cause contamination of soil and only for long-term exposure.

Risk assessment for the leaf scenario (field use in lettuce):

The exposure of birds to drinking water from pools in leaf whorls as outlined above cannot be excluded from the use of the product in lettuce.

The respective calculations for birds have to be performed only for acute exposure. Generic focal species is a small granivorous bird (body weight 15.3 g) with a DWR (daily drinking water rate) of 0.46 L/kg bw/d. It should be mentioned that DWR, unlike FIR in the case of food intake exposure assessment, is already related to body weight.

According to EFSA Guidance Document for Birds and Mammals (2009), the PECpool calculates as follows:

PECpool = Cspray / 5 [mg/L]

Cspray = 0.025 kg a.s./hL = 25 g a.s./hL = 0.25 g a.s./L = 250 mg a.s./L

The PECpool (= PECdw) is 250 / 5 = 50 mg a.s./L for BYI 02960. The calculation of DDD (here: daily drinking water uptake) and TER are as follows:

DDD = DWR * PECdw

TERA = LD50 [mg as/kg bw/d] / DDD [mg as/kg bw/d]

Table B.9.1.5.2-01: Tier 1 acute DDD and TER calculation for exposure via drinking water from pools in leaf axils or on leaves

Compound	**DWR [L/kg bw/d]**	**PECdw [mg/L]**	**DDD [mg/kg bw/d]**	**LD50 [mg/kg bw]**	**TER_A**	**Trigger**
BYI 02960	0.46	50	23	232	10.1	10

The TER_{AC} value for drinking water exposure exceeds the a-priori acceptability trigger of 10 in a worst case risk assessment (highest concentration in spray water volume, lowest LD50). Hence, no unacceptable risk is to be expected from the use of the product according to the intended use pattern.

Risk assessment for the puddle scenario (field use in hop and lettuce):

An “escape clause” recommended in the EFSA Guidance Document for Birds and Mammals (2009) allows for screening the need for a quantitative risk assessment by a comparison between the application rate and the toxicity of the respective substance. This escape clause specifies that “*due to*

the characteristics of the exposure scenario in connection with the standard assumptions for water uptake by animals …, no specific calculations of exposure and TER are necessary when the ratio of effective application rate (= application rate x MAF) (in g/ha) to relevant endpoint (in mg/kg bw/d) does not exceed 50 in the case of less sorptive substances (Koc < 500 L/kg) or 3000 in the case of more sorptive substances (Koc ≥ 500 L/kg).” [2].

Table B.9.1.5.2-02: Evaluation of potential concern for exposure of birds drinking water from puddles (escape clause)

Compound	Koc [mL/g]	Application rate * MAF [g a.i./ha]	LD50 or NO(A)EL [mg a.i./ kg bw/d]	Ratio (Application rate * MAF) / NO(A)EL	“Escape clause” No concern if ratio	Conclusion
BYI 02960	98.4 1)	150 2) x 1	232	0.64	≤ 50	No concern
			14	10.7	≤ 50	No concern

1) Arithmetic mean of ten K_{OC} values (see B.8)
2) Worst-case application rate in hops

This evaluation confirms that the risk for birds from drinking from puddles that may contain residues from the use of product is acceptable.

B.9.1.5.3 Bioaccumulation and food chain behaviour: Indirect exposure via contaminated worms or fish

Substances with a high bioaccumulation potential could theoretically bear a risk of secondary poisoning for birds if feeding on contaminated prey like fish or earthworms. For organic chemicals, a log P_{OW} > 3 is used to trigger an in-depth evaluation of the potential for bioaccumulation.

Table B.9.1.5.3-1: Log Pow values of BYI 02960 and its metabolites

Substance	Maximum Log Pow	Reference
BYI 02960	1.2	Vol.3 B.2.1.13
BYI 02960-succinamide	0.6 at pH 5	Vol.3 B.2 Table B.2.1-2 IIA 7.13b
BYI 02960-azabicyclosuccinamide NA-salt	-1.3 at pH 5	Vol.3 B.2 Table B.2.1-2 IIA 7.13b
DFA	- 3.1 at pH5	Vol.3 B.2 Table B.2.1-2 IIA 7.13b

[2] EFSA (2009): Guidance Document on Risk Assessment for Birds & Mammals on request from EFSA, p. 66

6-CNA	1.52 at pH 1.98	Vol.3 B.2 Table B.2.1-2 IIA 7.13b

As neither the active ingredient nor any of its metabolites has a log Pow above 3, the potential of bioaccumulation is considered to be low. Hence, there is no need to evaluate potential effects of secondary poisoning of birds.

B.9.2.1.1 Acute toxicity of the active substance (IIA 8.2.1; IIA 8.3.1; IIA 8.5.1)

STUDY IIA, 8.2.1.1/01

Characteristics

reference	:	[redacted](2010a)	water solubility	:	3000-3200 mg/L at pH 4-9 & 20°C
type of study	:	Acute toxicity study	species	:	Rainbow trout (*Oncorhynchus mykiss*)
year of execution	:	2009	exposure duration	:	96 hours
GLP statement	:	Yes	nominal concn.	:	5, 10, 20, 40 and 80 mg a.s./L
guideline	:	FIFRA 72-1, OPPTS 850.1075, OECD 203	dosing method	:	Static; stock solution in DMF
test substance	:	BYI 02960 technical, batch 2009-000239	acceptability	:	Acceptable
purity	:	96.2%	96-h LC50	:	>74.2 mg a.s./L

Methods

A 96-hour acute toxicity test in juvenile rainbow trout (*Oncorhynchus mykiss*) (1 replicate of ten fish per concentration, not fed for 48 hours prior to testing) was conducted under static conditions with BYI 02960 technical at test concentrations of 5, 10, 20, 40 and 80 mg a.s./L. It was reported that numerous preliminary trials demonstrated that a solvent stock would be needed to achieve maximum solubility in dilution water. The test solutions were prepared by adding aliquots of a stock solution in DMF to test water (max 0.1 mL/L DMF). The test included untreated and solvent controls (0.1 mL/L DMF). The concentrations of BYI 02960 were analytically confirmed by LC-MS/MS in samples of all test solutions taken at the start and end of exposure.

Results

The measured concentrations represented 72-99% of nominals at the start and 69-92% at the end of exposure. Test endpoints were based on mean measured concentrations (3.52, 8.31, 19.0, 35.1 and 74.2 mg a.s./L). Water quality parameters (pH, oxygen concentration and temperature) were in accordance with the OECD 203 guideline. No mortality and clinical signs were observed in any of the treatments and the controls. The 96-hour LC50 is >74.2 mg a.s./L.

Conclusion

96-hour LC50 >74.2 mg a.s./L.

Guidelines and limitations

The study is acceptable.

STUDY IIA, 8.2.1.2/01

Characteristics

year of execution	:	2009	exposure duration	:	96 hours
GLP statement	:	Yes	nominal concn.	:	5, 10, 20, 40 and 80 mg a.s./L
guideline	:	FIFRA 72-1, OPPTS 850.1075, OECD 203	dosing method	:	Static; stock solution in DMF
test substance	:	BYI 02960 technical, batch 2009-000239	acceptability	:	Acceptable
purity	:	96.2%	96-h LC50	:	>70.5 mg a.s./L

Methods

A 96-hour acute toxicity test in juvenile fathead minnow (*Pimephales promelas*) (1 replicate of ten fish per concentration, not fed for 48 hours prior to testing) was conducted under static conditions with BYI 02960 technical at test concentrations of 5, 10, 20, 40 and 80 mg a.s./L. It was reported that numerous preliminary trials demonstrated that a solvent stock would be needed to achieve maximum solubility in dilution water. The test solutions were prepared by adding aliquots of a stock solution in DMF to test water (max 0.1 mL/L DMF). The test included untreated and solvent controls (0.1 mL/L DMF). The concentrations of BYI 02960 were analytically confirmed by LC-MS/MS in samples of all test solutions taken at the start and end of exposure.

Results

The measured concentrations represented 80-96% of nominals at the start and 85-98% at the end of exposure. Test endpoints were based on mean measured concentrations (4.29, 9.00, 19.4, 34.3 and 70.5 mg a.s./L). Water quality parameters (pH, oxygen concentration and temperature) were in accordance with the OECD 203 guideline. No mortality and clinical signs were observed in any of the treatments and the controls. The 96-hour LC50 is >70.5 mg a.s./L.

Conclusion

96-hour LC50 >70.5 mg a.s./L.

Guidelines and limitations

The study is acceptable.

STUDY IIA, 8.2.1.2/02

Characteristics

reference	:	[redacted](2011a)	water solubility	:	3000-3200 mg/L at pH 4-9 & 20°C
type of study	:	Acute toxicity study	species	:	Common carp (*Cyprinus carpio*)
year of execution	:	2011	exposure duration	:	96 hours
GLP statement	:	Yes	nominal concn.	:	100 mg a.s./L (limit test)
guideline	:	FIFRA 72-1, OPPTS 850.1075, EEC C.1, OECD 203	dosing method	:	Static; stock solution in DMF
test substance	:	BYI 02960 (tech), batch BYI 02960-01-03 (original batch number 2009-000239)	acceptability	:	Acceptable
purity	:	96.2%	96-h LC50	:	>100 mg a.s./L

Methods

A 96-hour acute toxicity limit test in juvenile carp (*Cyprinus carpio*) (2 replicates of 15 fish, not fed for 48 hours prior to testing) was conducted under static conditions with BYI 02960 technical at a nominal test concentration of 100 mg a.s./L. The test solutions were prepared by adding aliquots of a stock solution in DMF to test water (max 0.1 mL/L DMF). The test included untreated and solvent controls (0.1 mL/L DMF). The concentrations of BYI 02960 were analytically confirmed by LC-MS/MS in samples of all replicates taken at the start, after 48 hours and at the end of exposure.

Results

The measured concentrations represented 101-120% of nominals at the start and 97-104% after 48 hours and at the end of exposure. The value of 120% for 1 replicate was the average of two injections, one giving 147% of nominal and the other one giving 92% of nominal. The value for 147% of nominal may be considered an outlier, since the results clearly demonstrated that the test substance was stable under the test conditions, and measured concentrations in the same replicate were 101-104% of nominal after 48 and 96 hours. Test endpoints were based on nominal concentrations, which is acceptable. Water quality parameters (pH, oxygen concentration and temperature) were in accordance with the OECD 203 guideline. No mortality and clinical signs were observed in the treated and control replicates. The 96-hour LC50 is >100 mg a.s./L.

Conclusion

96-hour LC50 >100 mg a.s./L.

Guidelines and limitations

The study is acceptable.

type of study	:	acute toxicity	species	:	frog *Xenopus laevis*
year of execution	:	2011	exposure duration	:	48 hours
GLP statement	:	Yes	nominal concn.	:	80 mg a.s./L (limit test)
guideline	:	EPA OPPTS 850.1075, FIFRA, 40 CFR, part 158, guideline 72-1, OECD 203 (1992).	dosing method	:	Static; stock solution in DMF
test substance	:	BYI 02960 technical, Batch number: 2009-000239, beige powder.	acceptability	:	Acceptable
purity	:	96.2%	96-h LC50	:	>80 mg a.s./L

Description

Methods. Acute toxicity of BYI 02960 to the tadpole *Xenopus laevis* from a commercial provider, was tested under static conditions. A limit test at a nominal concentration of 80 mg as/L (the functional limit of solubility ot the test substance in fresh water), control, and a solvent control (dimethylformamide 0.1 mL/L) was performed. A stock solution (800 g as/L) was prepared and diluted with test water to the nominal test concentration of 80 mg as/L. Test water was pring water blended with dechlorinated reverse osmosis water (hardness 180 mg/L, pH 8.4, conductivity 457 µmhos/cm). Tadpoles were acclimated for 4 days under test conditions. Tadpoles were 15.0 ± 0.97 mm at the experimental start. Three replicates with 10 tadpoles each, 7 L solution per unit. Observation on mortality, signs of toxicity and abnormal behaviour were performed 6, 24, and 48 h after test initiation.
Conditions. 21.5 – 22.0 ºC, 16:8 h L:D (739 - 1040 lux with 30 minutes transition period), no aeration, no feeding.
Chemical analysis. Samples were taken at the start and end of the study to determine actual concentrations. Stock solution was also analysed. Analysis by HPLC with MS detection, after dilution with HPLC-grade water. Method recovery of spiked solutions was 94 – 102% (mean 98%). LOQ 8.0 mg as/L.
Calculations and statistics. No statistical calculations were necessary.

Results

Measured concentration at the start was 64.7 mg as/L (81% of nominal) and after 48 hours 82.9 mg as/L (104% of nominal). Mean measured concentration was 73.8 mg as/L (92% of nominal). Measured concentration at test initiation was always lower than concentration measured at the end of the test. The test substance was stable during the experiment. Test solutions were clear, no precipitation. No mortality in control, solvent control and test concentration. All tadpoles appeared healthy and normal. LC_{50} for 48 hours exposure reported as > 80 mg as/L, based on nominal concentration.

Remarks by RMS

Water quality parameters within accepted range. The result 48-h LC_{50} > 80 mg/L, based on nominal concentrations, is used for risk assessment.

STUDY IIA, 8.3.1.1/01

Characteristics

reference	:	Banman C.S. & Lam C.V. (2009a)	water solubility	:	3000-3200 mg/L at pH 4-9 & 20°C
type of study	:	Acute toxicity study	species	:	*Daphnia magna*
year of execution	:	2009	exposure duration	:	48 hours
GLP statement	:	Yes	nominal concn.	:	80 mg a.s./L
guideline	:	FIFRA 72-2, OPPTS 850.1010, OECD 202	dosing method	:	Static; stock solution in DMF
test substance		BYI 02960 technical, batch 2009-000239	acceptability	:	Acceptable
purity	:	96.2%	48 h-EC50	:	>77.6 mg a.s./L

Methods

A 48-hour acute toxicity test in *Daphnia magna* (<24 h old, 6 replicates of five daphnia each for the treatment and each of the controls) was conducted under static conditions with BYI 02960 technical at a nominal test concentration of 80 mg a.s./L, with untreated control and solvent control (0.1 mL/L DMF). The concentrations of BYI 02960 were analytically confirmed by a sufficiently validated LC-MS/MS method in samples of all test solutions taken at the start and end of exposure.

Results

The measured concentration was 102% of nominal at the start and 92% at the end of exposure. Test endpoinst were based on the mean measured concentration (77.6 mg a.s./L). Water quality parameters (pH, oxygen concentration and temperature) were in accordance with the OECD 202 guideline. No mortality and signs of intoxication were observed in any replicate. The 48-hour EC50 is >77.6 mg a.s./L.

Conclusion

48-hour EC50 >77.6 mg a.s./L.

Guidelines and limitations

The study is acceptable.

STUDY IIA, 8.3.1.2/01

Characteristics

reference	:	Bruns E. (2011e)	water solubility	:	3000-3200 mg/L at pH 4-9 & 20°C
type of study	:	Acute toxicity study	species	:	*Chironomus riparius*
year of execution	:	2011	exposure duration	:	48 hours
GLP statement	:	Yes	nominal concn.	:	3.125, 6.25, 12.5, 25, 50 and 100 µg a.s./L
guideline	:	OPPTS 850.1300, OECD 202	dosing method	:	Static; direct addition to test water
test substance	:	BYI 02960 (tech.), batch 2009-000239 (batch code BYI 02960-01-03)	acceptability	:	Acceptable
purity	:	96.2%	48 h-EC50	:	61.7 µg a.s./L

Methods

A 48-hour acute toxicity test in *Chironomus riparius* (2-3 day old first instar larvae, 4 replicates of 10 larvae each for the treatments and the control) was conducted under static conditions with BYI 02960 technical at nominal test concentrations of 3.125, 6.25, 12.5, 25, 50 and 100 µg a.s./L, with untreated control. The test solution of the highest concentration was prepared by adding the test substance directly to the test water. Lower concentrations were prepared by serial dilution. A small amount of feed (0.01 mL of an aqueous fish food suspension) was added immediately after addition of the larvae. The concentrations of BYI 02960 were analytically confirmed by a sufficiently validated LC-MS/MS method in samples of all test solutions taken at the start and end of exposure.

Results

The measured concentrations were 97-103% of nominal at the start and 101-107% at the end of exposure. Test endpoints were based on nominal concentrations, which is acceptable. Water quality parameters (pH, oxygen concentration and temperature) were in accordance with the OECD 202 guideline. At 0, 3.125, 6.25, 12.5, 25, 50 and 100 µg a.s./L, respectively, immobility was 0%, 0%, 0%, 2.5%, 2.5%, 30% and 85%. The reported 48-hour EC50 (Probit analysis) was 61.7 µg a.s./L (95% CI 41.4-109 µg a.s./L. At 100 µg a.s./L, surviving larvae showed reduced immobility.

Conclusion

48-hour EC50 61.7 µg a.s./L.

Guidelines and limitations

The study is acceptable.

STUDY IIA, 8.4/01

Characteristics

reference	:	Banman C.S. & Lam C.V. (2010)	water solubility	:	3000-3200 mg a.s./L at pH 4-9 & 20°C
type of study	:	Algae growth inhibition	species	:	*Pseudokirchneriella subcapitata*
year of execution	:	2010	exposure duration	:	96 hours
GLP statement	:	Yes	nominal concn.	:	5, 10, 20, 40 and 80 mg a.s./L
guideline	:	FIFRA 123-2, OPPTS 850.5400, OECD 201 (2006)	dosing method	:	Static; stock solution in DMF
test substance	:	BYI 02960 technical, batch 2009-000239	acceptability	:	Acceptable
purity	:	96.2%	72h-ErC50 & EyC50	:	>80 mg a.s./L

Methods

A 96-hour toxicity test on green algae (*Pseudokirchneriella subcapitata*) (3 replicates for the treatment and the untreated and solvent controls, each containing 1 x 10^4 cells/mL at the start) was conducted with BYI 02960 technical at test concentrations of 5, 10, 20, 40 and 80 mg a.s./L. The solution of the highest concentration was prepared by adding an aliquot of a stock solution in DMF to test water (0.1 mL/L DMF). The lower concentrations were prepared by serial dilution of this solution. The concentrations of BYI 02960 were analytically confirmed by a sufficiently validated LC-MS/MS method in samples of all test solutions taken at the start and end of exposure.

Results

The measured concentrations were in the range 111-120% of nominal at the start and end of exposure. Test endpoints were based on nominal concentrations, which is acceptable. Physico-chemical parameters were in accordance with the OECD 201 guideline. The pH increased from 7.3-7.4 at the start to 10.1-10.3 at the end, but this is associated with CO_2 depletion due to strong cell growth in the controls and all treaments and does not invalidate the test. The mean growth factor in the controls was 144 within 72 hours. The mean CV of the section-by-section specific growth rates in the control was 13%. The CV of the average specific growth rate in the control during the 72-hour

period was 1.0%. Hence the validity criteria of OECD 201 (2006) were satisfied. The % inhibition range for specific growth rate and area under the curve (biomass), respectively, were in the range -3.3 to -1.0% and -3.5 to -17.7%. The 72-h ErC50 and EbC50 was >80 mg a.s./L. The 72-h EyC50 was not reported, but clearly also in excess of 80 mg a.s./L.

Conclusion

72-h ErC50, EbC50 and EyC50 >80 mg a.s./L.

Guidelines and limitations

The study is acceptable.

STUDY IIA, 8.6/01

Characteristics

Reference	:	Banmann C.S. *et al* (2010)	species	:	Duckweed (*Lemna gibba G3*)
type of study	:	Duckweed growth inhibition test	duration	:	7 days
year of execution	:	2010	nominal conc.	:	5, 10, 20, 40 and 80 mg a.s./L
GLP statement	:	Yes	dosing method	:	Semi-static; stock solution in DMF
guideline	:	FIFRA 123-2, OECD 221 (2006) & OPPTS 850.4400	acceptability	:	Acceptable
test substance	:	BYI 02960 technical, batch 2009-000239	Lowest NOEC	:	34.2 mg a.s./L
purity	:	96.2%	Lowest EC50	:	>67.7 mg a.s./L

Methods

A 7-day toxicity test on the growth of duckweed (*Lemna gibba G3*) (3 replicates per concentration, each containing three plants with four fronds each at test initiation) was conducted under semi-static conditions (renewal on day 3) with BYI 02960 technical at nominal test concentrations of 5, 10, 20, 40 and 80 mg a.s./L, with untreated and solvent control each tested in 3 replicates. The solution of the highest concentration was prepared by adding an aliquot of a stock solution in DMF to test water (0.1 mL/L DMF). The lower concentrations were prepared by serial dilution of this solution (including addition of solvent such that the final concentration of DMF was 0.1 mL/L in all treatments). The concentrations of BYI 02960 were analytically confirmed by a sufficiently validated LC-MS/MS method in samples of all test solutions taken at the start (fresh solutions), on day 3 (aged and fresh solutions) and at the end of exposure (aged solutions). On day 0, 3, 5 and 7, frond number and any change in plant development were recorded. Frond dry weight was recorded on day 0 and 7.

Results

The measured concentrations in the test solutions taken on day 0 (fresh), day 3 (aged and fresh) and day 7 (aged) were in the range 65-68%, 71-77%, 86-104% and 93-101%, respectively. The mean measured concentrations were in the range 80-86% of nominal: 4.02, 8.17, 16.0, 34.2 and 67.7 mg a.s./L. The test endpoints were based on mean measured concentrations.

Water quality parameters (light intensity, pH and temperature) were in accordance with the OECD 221 guideline. The doubling time in the control was 1.65 days, hence the validity criterion of OECD 221

(2006) was satisfied (doubling time <2.5 days). Phytotoxic effects were not observed in any treatment. Other test results are summarised in the Table below.

All EC50 values are >67.7 mg a.s./L as effects at the highest test concentration were well below 50% for all parameters. No statistically significant effects on yield and growth rate based on biomass were recorded, hence the corresponding NOECs are 67.7 mg a.s./L. Based on statistically significant reductions of yield and growth rate based on frond number at the highest tested concentration, the corresponding NOECs are 34.2 mg a.s./L.

The report also calculated percentage inhibition values for cumulative biomass based on frond number: 13%, 10%, 19%, 8% and 29% at 4.02, 8.17, 16.0, 34.2 and 67.7 mg a.s./L, respectively, with statistical significance (5% level) reached at 16.0 and 67.7 mg a.s./L. The author of the report stated that the statistically significant reduction of 19% at 16.0 mg a.s./L was unrelated to the treatment, since the next higher dose level was unaffected, and since in a pre-test at 16 mg a.s./L the inhibition was -1.5% for fround counts. This is acceptable. In addition, this parameter is not required by OECD 221.

Table B.9.2.1.1-01 The toxicity of BYI 02960 technical to *Lemna gibba*

Mean measured conc. (mg a.s./L)	frond number			biomass		
	mean no. of fronds (day 7)	% inhibition growth rate	% inhibition yield	mean biomass (mg d.w.) (day 7)	% inhibition growth rate	% inhibition yield
Control	238	-	-	27.2	-	-
Solvent cont	217	-	-	25.2	-	-
Pooled con	228	-	-	26.2	-	-
4.02	208	3.0	8.4	23.8	3.6	9.0
8.17	215	2.0	5.5	24.9	2.0	4.8
16.0	191	5.9	16.0	23.0	4.9	12.3
34.2	219	1.5	3.7	28.0	-1.7	-6.8
67.7	169	10.3*	25.9*	21.5	7.7	17.9

* statistically significant difference from control at 5% level.

Conclusion

Semi-static test: lowest NOEC 34.2 mg a.s./L, lowest EC50 >67.7 mg a.s./L.

Guidelines and limitations

The test was performed in agreement with OECD 221 and is acceptable.

STUDY IIA, 8.11.1/02

Characteristics

Methods

A 96-hour shell deposition test in Eastern oyster (*Crassostrea virginica*) (1 replicate of 20 oysters per concentration) was conducted under flow-through conditions with BYI 02960 technical at test concentrations of 0.94, 1.9, 3.8, 7.5, 15 and 30 mg a.s./L. The test included untreated and solvent controls (0.1 mL/L DMF). The concentrations of BYI 02960 were analytically confirmed by a sufficiently validated HPLC/UV method in samples of all test solutions taken at the start, after 48 hours and at the end of exposure.

Results

The measured concentrations represented 94-100% of nominals. Test endpoints were based on mean measured concentrations (0.90, 1.8, 3.6, 7.3, 15 and 29 mg a.s./L). Water quality parameters (pH, oxygen concentration, temperature and salinity) were in accordance with the OPPTS 850.1025 guideline (pH 8.1-8.2, dissolved oxygen ≥6.9 mg/L(≥86% of saturation), 19.2-21.1°C, salinity 20$^{0}/_{00}$). The validity criteria of OPPTS 850.1025 were satisfied (mortality <10%, dissolved oxygen >60%, no evidence of spawning, >2 mm shell growth in controls). No mortality was observed in any of the treatments and the controls. At 0.90, 1.8, 3.6, 7.3, 15 and 29 mg a.s./L, respectively, inhibition of shell growth was 2.2, 2.9, -13, 13, -19 and 13%. None of the differences between the treated groups and the pooled control were statistically significant at the 5% uncertainty level. The 96-hour EC50 is >29 mg a.s./L.

Conclusion

96-hour EC50 >29 mg a.s./L.

Guidelines and limitations

The study is acceptable.

STUDY IIA, 8.11.1/03

Characteristics

reference	:	Gallagher S.P. et al. (2009b)	water solubility	:	3000-3200 mg/L at pH 4-9 & 20°C
type of study	:	Acute toxicity study (marine organism)	species	:	Salt water mysid (*Americamysis bahia*)
year of execution	:	2009	exposure duration	:	96 hours
GLP statement	:	Yes	nominal concn.	:	0.13, 0.22, 0.36, 0.60 and 1.0 mg a.s./L
guideline	:	OPPTS 850.1035	dosing method	:	Static; test substance dissolved in test water
test substance	:	BYI 02960 technical, batch 2009-000239	acceptability	:	Acceptable for juveniles (not tested whether these are most sensitive life-stage)
purity	:	96.2%	96-h LC50	:	0.26 mg a.s./L

Methods

A 96-hour acute toxicity test on juveniles (<24 h old) of the saltwater mysid *Americamysis bahia* (2 replicates of 10 mysids per concentration) was conducted under static conditions with BYI 02960 technical at test concentrations of 0.13, 0.22, 0.36, 0.60 and 1.0 mg a.s./L. The test included untreated controls. The concentrations of BYI 02960 were analytically confirmed by a sufficiently validated HPLC/UV method in samples of all test solutions taken at the start, after 48 hours and at the end of exposure.

Results

The measured concentrations represented 94-98% of nominals. Test endpoints were based on mean measured concentrations (0.12, 0.21, 0.35, 0.58 and 0.98 mg a.s./L). Water quality parameters (pH, oxygen concentration, temperature and salinity) were in accordance with the OPPTS 850.1035 guideline (pH 8.1-8.2, dissolved oxygen ≥6.5 mg/L(≥89% of saturation), 23.2-25.7°C, salinity 20$^{0}/_{00}$). No mortality was observed in the controls. At 0.12, 0.21, 0.35, 0.58 and 0.98 mg a.s./L, respectively, mortality was 5, 60, 50, 100 and 100%. Signs of toxicity were noted at 0.21 mg a.s./L and above. The 96-hour LC50 was 0.26 mg a.s./L (95% CI 0.12-0.58 mg a.s./L.

Conclusion

96-hour LC50 0.26 mg a.s./L.

Guidelines and limitations

The study result is acceptable for juvenile mysids. The OPPTS 850.1035 guideline states that a range-finding test should be conducted to determine which life stage (juvenile or young adult) is to be utilized in the definitive test. The definitive test should be conducted on the mysid life stage (juveniles or young adults) which is most sensitive to the test substance. The report did not state that a range-finding test was conducted with juveniles and young adults, hence it is unclear whether the juveniles tested were the most sensitive life stage.

B.9.2.1.2 Acute toxicity of metabolites (IIA 8.2.1, IIA 8.3.1)

STUDY IIA, 8.2.1.3/01

Characteristics

reference	:	[redacted](2011b)	water solubility	:	No data
type of study	:	Acute toxicity study	species	:	Rainbow trout (*Oncorhynchus mykiss*)
year of execution	:	2011	exposure duration	:	96 hours
GLP statement	:	Yes	nominal concn.	:	100 mg metabolite/L (limit test)
guideline	:	FIFRA 72-1, OPPTS 850.1075, EEC C.1, OECD 203	dosing method	:	Static; stock solution in DMF
test substance	:	BYI 02960-succinamide; batch BCS-CR74729-01-01 (original batch number BCOO 6329-2-10)	acceptability	:	Acceptable
purity	:	97.8%	96-h LC50	:	>100 mg metabolite/L

Methods

A 96-hour acute toxicity limit test in juvenile rainbow trout (*Oncorhynchus mykiss*) (2 replicates of 15 fish, not fed for 48 hours prior to testing) was conducted under static conditions with BYI 02960-succinamide (metabolite of BYI 02960) at a nominal test concentration of 100 mg metabolite/L. The test solutions were prepared by adding a solution in DMF to the test water. The test included untreated and solvent controls (0.1 mL/L DMF). The concentrations of BYI 02960-succinamide were analytically confirmed by LC-MS/MS in samples of all replicates taken at the start, after 48 hours and at the end of exposure.

Results

The measured concentrations represented 112-115% of nominals (overall range for 0-, 48- and 96-hour samples). Test endpoints were based on nominal concentrations, which is acceptable. Water quality parameters (pH, oxygen concentration and temperature) were in accordance with the OECD 203 guideline. No mortality was observed in the treated and control replicates. Two fish died in one of the two solvent control replicates. This does not invalidate the test since the overall mortality rate in the solvent control was 6.7%, hence <10%, and in the pooled controls 3.3%. No signs of intoxication were observed in the control and treated replicates and in the surviving fish of the solvent control. The 96-hour LC50 is >100 mg metabolite/L.

Conclusion

96-hour LC50 >100 mg metabolite/L.

Guidelines and limitations

The study is acceptable.

STUDY IIA, 8.2.1.3/02

Characteristics

reference	:	[redacted] (2011c)	water solubility	:	No data
type of study	:	Acute toxicity study	species	:	Rainbow trout (*Oncorhynchus mykiss*)
year of execution	:	2010	exposure duration	:	96 hours
GLP statement	:	Yes	nominal concn.	:	10.0 mg metabolite/L (limit test)
guideline	:	FIFRA 72-1, OPPTS 850.1075, EEC C.1, OECD 203	dosing method	:	Static; direct addition to test water
test substance	:	BCS-AB60481 (tech.) = sodium difluoroacetate; batch BCS-AB60481-01-01 (original batch number BCOO 6092-3-1)	acceptability	:	Acceptable
purity	:	>99.0%	96-h LC50	:	>10.0 mg metabolite/L

Methods

A 96-hour acute toxicity limit test in juvenile rainbow trout (*Oncorhynchus mykiss*) (2 replicates of 15 fish, not fed for 48 hours prior to testing) was conducted under static conditions with BCS-AB60481 (tech.) (sodium difluoroacetate; metabolite of BYI 02960 technical) at a nominal test concentration of 10.0 mg metabolite/L. The test solutions were prepared by adding the test substance directly to the test water. The test included untreated controls. The concentrations of sodium difluoroacetate were

analytically confirmed by LC-MS/MS in samples of all replicates taken at the start, after 48 hours and at the end of exposure.

Results

The measured concentrations represented 100-105% of nominals (overall range for 0-, 48- and 96-hour samples). Test endpoints were based on nominal concentrations, which is acceptable. Water quality parameters (pH, oxygen concentration and temperature) were in accordance with the OECD 203 guideline. No mortality and sublethal effects were observed in the treated and control replicates. The 96-hour LC50 is >10.0 mg metabolite/L.

Conclusion

96-hour LC50 >10.0 mg metabolite/L.

Guidelines and limitations

The study is acceptable.

STUDY IIA, 8.3.1.1/02

Characteristics

reference	:	Bruns E. (2011d)	water solubility	:	No data
type of study	:	Acute toxicity study	species	:	*Daphnia magna*
year of execution	:	2011	exposure duration	:	48 hours
GLP statement	:	Yes	nominal concn.	:	10 mg metabolite/L (limit test)
guideline	:	OPPTS 850.1300, EEC C.2, OECD 202	dosing method	:	Static; direct addition to test water
test substance	:	BCS-AB60481 (tech.) = sodium difluoroacetate; batch BCS-AB60841-01-01 (original batch number BCOO 6092-3-1)	acceptability	:	Acceptable
purity	:	>99.0%	48 h-EC50	:	>10 mg metabolite/L

Methods

A 48-hour acute toxicity test in *Daphnia magna* (<24 h old, 12 replicates of five daphnia each for the treatment and the control) was conducted under static conditions with BCS-AB60481 (tech.) (sodium difluoroacetate; metabolite of BYI 02960 technical) at a nominal test concentration of 10 mg metabolite/L, with untreated control. The test solutions were prepared by adding the test substance directly to the test water. The concentrations of sodium difluoroacetate were analytically confirmed by a sufficiently validated LC-MS/MS method in samples of all replicates taken at the start and end of exposure.

Results

The measured concentration was 101% of nominal at the start and 103% at the end of exposure. Test endpoints were based on the nominal concentration, which is acceptable. Water quality parameters (pH, oxygen concentration and temperature) were in accordance with the OECD 202 guideline. No

mortality and signs of intoxication were observed in any replicate. The 48-hour EC50 is >10 mg metabolite/L.

Conclusion

48-hour EC50 >10 mg metabolite/L.

Guidelines and limitations

The study is acceptable.

STUDY IIA, 8.3.1.1/03

Characteristics

reference	:	Mc Elligott A. (1997)	water solubility	:	1.43 g/L at 20°C
type of study	:	Acute toxicity study	species	:	*Daphnia magna*
year of execution	:	1997	exposure duration	:	48 hours
GLP statement	:	Yes	nominal concn.	:	6.3, 12.5, 25, 50 and 100 mg/L
guideline	:	FIFRA 72-2, EEC C.2, OECD 202	dosing method	:	Static; direct addition to test water
test substance	:	IC-0 (metabolite of BYI 02960, batch MF-4267, elsewhere named 6-CNA)	acceptability	:	Acceptable
purity	:	99.7%	48 h-EC50	:	>95.1 mg/L

Methods

A 48-hour acute toxicity test in *Daphnia magna* (<24 h old, 2 replicates of 10 daphnia each for the treatments and the control) was conducted under semi-static conditions (renewal after 24 hours) with IC-0 (metabolite of BYI 02960) at nominal test concentrations of 6.3, 12.5, 25, 50 and 100 mg/L, with untreated control. The test solutions of the highest concentration was prepared by adding the test substance directly to the test water. Lower concentrations were prepared by serial dilution. The concentrations of IC-0 were analytically confirmed by a sufficiently validated HPLC/UV method in samples of all treatments taken at the start and end of each renewal period.

Results

The measured concentrations were 94-96% of nominal at the start and 94-97% at the end of the renewal periods. Test endpoints were based on the mean measured concentrations, which is acceptable (6.0, 11.9, 23.9, 47.2 and 95.1 mg/L). Water quality parameters (pH, oxygen concentration and temperature) were in accordance with the OECD 202 guideline. No mortality and signs of intoxication were observed in any replicate, except for one immobile daphnid at 47.2 mg/L, but this was considered to be unrelated to the treatment. The 48-hour EC50 is >95.1 mg/L.

Conclusion

48-hour EC50 >95.1 mg/L.

Guidelines and limitations

The study is acceptable.

STUDY IIA, 8.3.1.2/02

Characteristics

reference	:	Bruns E. (2011f)	water solubility	:	No data
type of study	:	Acute toxicity study	species	:	*Chironomus riparius*
year of execution	:	2011	exposure duration	:	48 hours
GLP statement	:	Yes	nominal concn.	:	26, 36, 51, 71 and 100 mg pure metabolite/L
guideline	:	OECD 202, OPPTS 850.supp	dosing method	:	Static; direct addition to test water
test substance	:	BYI 02960-succinamide; batch BCS-CR74729 (original batch number BCOO 6329-2-10)	acceptability	:	Acceptable
purity	:	97.8%	48 h-EC50	:	>100 mg pure metabolite/L

Methods

A 48-hour acute toxicity test in *Chironomus riparius* (2-3 day old first instar larvae, 4 replicates of 10 larvae each for the treatments and the control) was conducted under static conditions with BYI 02960-succinamide (metabolite of BYI 02960) at nominal test concentrations of 26, 36, 51, 71 and 100 mg pure metabolite/L, with untreated control. The test solutions were prepared by serial dilution from a stock solution prepared in test water. A small amount of feed (0.01 mL of an aqueous fish food suspension) was added immediately after addition of the larvae. The concentrations of BYI 02960-succinamide were analytically confirmed by a sufficiently validated LC-MS/MS method in samples of all test solutions taken at the start and end of exposure.

Results

The measured concentrations were 103-106% of nominal at the start and 102-107% at the end of exposure. Test endpoints were based on nominal concentrations, which is acceptable. Water quality parameters (pH, oxygen concentration and temperature) were in accordance with the OECD 202 guideline. At 0, 26, 36, 51, 71 and 100 mg pure metabolite/L, respectively, immobility was 0%, 0%, 0%, 2.5%, 2.5% and 15%. The 48-hour EC50 was >100 mg pure metabolite/L.

Conclusion

48-hour EC50 >100 mg pure metabolite/L.

Guidelines and limitations

The study is acceptable.

STUDY IIA, 8.3.1.2/03

Characteristics

reference	:	Bruns E. (2012a)	water solubility	:	No data
type of study	:	Acute toxicity study	species	:	*Chironomus riparius*
year of execution	:	2011	exposure duration	:	48 hours
GLP statement	:	Yes	nominal concn.	:	26, 36, 51, 71 and 100 mg pure metabolite/L
guideline	:	OECD 235	dosing method	:	Static; direct addition to test water
test substance	:	BYI 02960-azabicyclosuccinamide,	acceptability	:	Acceptable

		sodium salt; batch SES 11732-3-1			
purity	:	48.0%	48 h-EC50	:	>100 mg pure metabolite/L

Methods

A 48-hour acute toxicity test in *Chironomus riparius* (2-3 day old first instar larvae, 6 replicates of 5 larvae each for the treatments and the control) was conducted under static conditions with BYI 02960-azabicyclosuccinamide, sodium salt (metabolite of BYI 02960) at nominal test concentrations of 26, 36, 51, 71 and 100 mg pure metabolite/L, with untreated control. The test solutions were prepared by serial dilution from a stock solution prepared in test water. A few drops of an aqueous fish food suspension were added prior to insertion of the larvae. The concentrations of BYI 02960-azabicyclosuccinamide were analytically confirmed by a sufficiently validated LC-MS/MS method in samples of all test solutions taken at the start and end of exposure.

Results

The measured concentrations were 107-112% of nominal at the start and 117-120% at the end of exposure. Test endpoints were based on nominal concentrations, which is acceptable. Water quality parameters (pH, oxygen concentration and temperature) were in accordance with the OECD 202 guideline. At 0, 26, 36, 51, 71 and 100 mg pure metabolite/L, respectively, immobility was 0%, 0%, 0%, 3.3%, 3.3% and 20%. The 48-hour EC50 was >100 mg pure metabolite/L.

The results of the most recently conducted test with the reference substance 3,5-dichlorophenol (48-h EC50 3.1 mg/L) was within the range defined by OECD 235 (0.50-3.6 mg/L).

Conclusion

48-hour EC50 >100 mg pure metabolite/L.

Guidelines and limitations

The study is acceptable.

STUDY IIA, 8.3.1.2/04

Characteristics

reference	:	Bowers L.M. & Lam C.V. (1998)	water solubility	:	2 g/L (reported value)
type of study	:	Acute toxicity study	species	:	*Chironomus tentans*
year of execution	:	1998	exposure duration	:	96 hours
GLP statement	:	Yes	nominal concn.	:	1 mg/L
guideline	:	ASTM (1987), EPA (1972, 1982, 1985)	dosing method	:	Static; direct addition to test water
test substance	:	6-chloronicotinic acid (6-CNA = IC-0); batch 9931	acceptability	:	Acceptable
purity	:	97%	96 h-EC50	:	>1 mg/L

Methods

A 96-hour acute toxicity test in *Chironomus tentans* (12-day old adult larvae, 3 replicates of 10 larvae for the treatment and 1 replicate of 10 larvae for the control) was conducted under semi-static conditions (renewal after 2 days) with 6-chloronicotinic acid (6-CNA = IC-0, metabolite of BYI 02960) at a nominal test concentration of 1 mg/L, with untreated control. The test solution was prepared by dissolving the test substance in test water. Each replicate 1-L test dish contained 800 mL (6 cm) of test solution and 5 g of fine silica sand. The test organisms were fed 0.1 mL of blended Tetramin each day except day 2, when feeding was not necessary since the blended Tetramin was still present in the test vessels.

The concentrations of 6-chloronicotinic acid were not analytically confirmed in the test solutions. However, the stability of 6-chloronicotinic acid in deionised water was confirmed by HPLC/UV after two days at room temperature. Taking this into consideration, as well as the facts that the preparation of the test solutions was well documented, and that in study 4 of section B.9.2.1.2 6-chloronicotinic acid was stable during a 48-hour acute toxicity test with *Daphnia magna*, the lack of analytical confirmation of the concentrations of 6-chloronicotinic acid in the test solutions does not invalidate the study.

Results

The test temperature was 20.5-21.9°C, the pH was consistently 8.4 and the dissolved oxygen concentrations were 55-99% of saturation. Mortality was 10% in the control and 0% in the treated solutions. The 96-hour EC50 was >1 mg/L.

Conclusion

96-hour EC50 >1 mg/L.

Guidelines and limitations

An OECD guideline is not avaliable for acute toxicity testing of *C. tentans*. The use of 12-day old (3rd instar) larvae is recommended by EPA guidelines (1995) for 10-day tests with *C. tentans* in the presence of sediment. The study was evaluated in the DAR of imidacloprid (6-chloronicotinic acid is also a metabolite of imidacloprid) and considered to be valid. The study is acceptable.

STUDY IIA, 8.4/02

Characteristics

reference	:	Bruns E. (2011j)	water solubility	:	No data
type of study	:	Algae growth inhibition	species	:	*Pseudokirchneriella subcapitata*
year of execution	:	2010-2011	exposure duration	:	72 hours
GLP statement	:	Yes	nominal concn.	:	10 mg pure metabolite/L
guideline	:	OPPTS 850.5400, OECD 201 (2006)	dosing method	:	Static (spiked water)
test substance	:	sodium difluoroacetate; batch BCS-AB60841-01-01 (original batch number BCOO 6092-3-1)	acceptability	:	Acceptable
purity	:	>99.0%	72h-ErC50 & EyC50	:	>10 mg pure metabolite/L

Methods

A 72-hour toxicity test on green algae (*Pseudokirchneriella subcapitata*) (6 replicates for the treatment and the control, each containing 1 x 10^4 cells/mL at the start) was conducted with sodium difluoroacetate (metabolite of BYI 02960 technical) at a test concentration of 10 mg pure metabolite/L. The test solution was prepared by adding the test substance directly to the test water. The concentrations of sodium difluoroacetate were analytically confirmed by a sufficiently validated LC-MS/MS method in samples taken at the start and end of exposure.

Results

The measured concentrations were in the range 100-103% of nominal at the start and end of exposure. Test endpoints were based on nominal concentrations, which is acceptable. Physico-chemical parameters were in accordance with the OECD 201 guideline. The mean growth factor in the controls was 68 within 72 hours. The mean CV of the section-by-section specific growth rates in the control was 21.4%. The CV of the average specific growth rate in the control during the 72-hour period was 1.0%. Hence the validity criteria of OECD 201 (2006) were satisfied. The % inhibition for 0-72 h specific growth rate and yield, respectively, was 4.0% and 15.8% (both statistically significantly different from the control at 5% uncertainty level). The 72-h ErC50 and EyC50 was >10 mg pure metabolite/L.

Conclusion

72-h ErC50 and EyC50 >10 mg pure metabolite/L.

Guidelines and limitations

The study is acceptable.

GLP statement	:	Yes	nominal concn.	:	10 mg pure metabolite/L
guideline	:	OECD 201 (2006), OPPTS 850.5400	dosing method	:	Static (stock solution in DMF)
test substance	:	BYI 02960-succinamide; batch BCS-CR74729-01-01 (original batch number BCOO 6329-2-10)	acceptability	:	Acceptable
purity	:	97.8%	72h-ErC50 & EyC50	:	>10 mg pure metabolite/L

Methods

A 72-hour toxicity test on green algae (*Pseudokirchneriella subcapitata*) (6 replicates for the treatment and the control and solvent control, each containing 1 x 10^4 cells/mL at the start) was conducted with BYI 02960-succinamide (metabolite of BYI 02960) at a test concentration of 10 mg pure metabolite/L. The test solution was prepared by adding an aliquot of a stock solution in DMF to test water (0.1 mL/L

DMF). The concentrations of BYI 02960-succinamide were analytically confirmed by a sufficiently validated HPLC-UV method in samples taken at the start and end of exposure.

Results

The measured concentrations were in the range 113-114% of nominal at the start and end of exposure. Test endpoints were based on nominal concentrations, which is acceptable. Physico-chemical parameters were in accordance with the OECD 201 guideline. The mean growth factor in the pooled controls was 75 within 72 hours. The mean CV of the section-by-section specific growth rates in the control was 18.4%. The CV of the average specific growth rate in the control during the 72-hour period was 1.2%. Hence the validity criteria of OECD 201 (2006) were satisfied. The % inhibition for 0-72 h specific growth rate and yield, respectively, was 0.1% and 0.4% (both not statistically significantly different from the control at 5% uncertainty level). The 72-h ErC50 and EyC50 was >10 mg pure metabolite/L.

Conclusion

72-h ErC50 and EyC50 >10 mg pure metabolite/L.

Guidelines and limitations

The study is acceptable.

STUDY IIA, 8.4/04

Characteristics

reference	:	Bruns E. (2012b)	water solubility	:	2 g/L (from other report)
type of study	:	Algae growth inhibition	species	:	*Pseudokirchneriella subcapitata*
year of execution	:	2011	exposure duration	:	72 hours
GLP statement	:	Yes	nominal concn.	:	6.25, 12.5, 25, 50 and 100 mg pure metabolite/L
guideline	:	OPPTS 850.5400, OECD 201 (2006)	dosing method	:	Static (spiked water)
test substance	:	6-chloronicotinic acid (6-CNA = IC-0); batch AE F161089 00 1B99 0001	acceptability	:	Acceptable
purity	:	98.8%	72h-ErC50 72-h EyC50	:	>100 mg pure metabolite/L 85 mg pure metabolite/L

Methods

A 72-hour toxicity test on green algae (*Pseudokirchneriella subcapitata*) (3 replicates for each treatment and 6 for the control, each containing 1 x 10^4 cells/mL at the start) was conducted with 6-chloronicotinic acid (6-CNA = IC-0, metabolite of BYI 02960). A stock solution of the test substance was prepared in test water. The test solutions were prepared by adding an aliqout of this stock solution to test water. The test concentrations were 6.25, 12.5, 25, 50 and 100 mg pure metabolite/L. Since the test substance is an acid, the pH of the 100 mg/L test solution was 5.1. Therefore, at this concentration the test was conducted without pH adjustment (3 replicates) and with the pH adjusted to 8.2 (8.2 was the pH of the controls) (3 replicates). The concentrations of 6-chloronicotinic acid were

analytically confirmed by a sufficiently validated LC-MS/MS method in samples taken at the start and end of exposure.

Results

The measured concentrations were in the range 99-112% of nominal at the start and end of exposure. Test endpoints were based on nominal concentrations, which is acceptable. Physico-chemical parameters were in accordance with the OECD 201 guideline. The change in pH was within 0.7 units in all treatments, except at 100 mg/L without pH adjustment (pH after 0, 24, 48 and 72 hours 5.1, 6.6, 6.2 and 5.1, respectively). The mean growth factor in the controls was 102 within 72 hours. The mean CV of the section-by-section specific growth rates in the control was 32.8%. The CV of the average specific growth rate in the control during the 72-hour period was 2.9%. Hence the validity criteria of OECD 201 (2006) were satisfied.

Effects on 0-72 h specific growth rate were in the range -9.0 to 3.7% (negative values represent increases relative to control, hence no adverse effects), except for the 100 mg/L treatment without pH adjustment (31.5% inhibition, statistically significant difference from the control at 5% uncertainty level). Effects on 0-72 h yield were in the range -51.5% to 16%, except for the 100 mg/L treatment without pH adjustment (77.4% inhibition, statistically significant difference from the control at 5% uncertainty level). The report stated that for the treatments without pH adjustment the 72-h ErC50 and EyC50 was 114 and 85 mg pure metabolite/L, respectively, but the 72-h ErC50 is an extrapolated value. Without pH adjustment, the 72-h ErC50 is >100 mg pure metabolite/L. With pH adjustment, the 72-h ErC50 and EyC50 is >100 mg pure metabolite/L.

Conclusion

Without pH adjustment: 72-h ErC50 >100 mg pure metabolite/L, 72-h EyC50 85 mg pure metabolite/L.
With pH adjustment: 72-h ErC50 and EyC50 >100 mg pure metabolite/L.

Guidelines and limitations

The study is acceptable. The relevant endpoints are taken from the test without pH adjustment, since the acidification of the test medium (responsible for the effects noted without pH adjustment at 100 mg/L) is caused by the test substance.

B.9.2.1.3 Acute toxicity of the formulated product (IIIA 10.2.2.2)

STUDY IIIA, 10.2.2.1/01

Characteristics

reference	:	[redacted]. (2010a)	species	:	Rainbow trout (*Oncorhynchus mykiss*)
type of study	:	Acute toxicity study	exposure duration	:	96 hours
year of execution	:	2010	nominal concn.	:	100 mg a.s./L
GLP statement	:	Yes	dosing method	:	Static; direct addition to test water
guideline	:	OPPTS 850.1075, EEC C.1, OECD	acceptability	:	Acceptable

		203			
test substance	:	BYI 02960 SL 200 G (200 g/L SL formulation), batch 2010-001067	96-h LC50	:	>100 mg a.s./L
a.s. content	:	17.1 % w/w (201.0 g/L) BYI 02960			

Methods

A 96-hour acute toxicity limit test in juvenile rainbow trout (*Oncorhynchus mykiss*) (2 replicates of 15 fish, not fed for 48 hours prior to testing) was conducted under static conditions with BYI 02960 SL 200 G (SL formulation, 17.1 % w/w (201.0 g/L) BYI 02960) at a nominal test concentration of 100 mg a.s./L. The test included an untreated control, tested also in 2 replicates of 15 fish each. The concentrations of BYI 02960 were analytically confirmed by a sufficiently validated LC-MS/MS method in samples of all test solutions taken at the start, after 48 hours and at the end of exposure.

Results

The measured concentrations were in the range 103-107% of nominals at the start, after 48 hours and at the end of exposure. Test endpoints were based on nominal concentrations which is acceptable. Water quality parameters (pH, oxygen concentration and temperature) were in accordance with the OECD 203 guideline. No control fish died, and only one fish died (3% mortality) at 100 mg a.s./L. The clinical sign observed in all surviving treated fish after 96 hours of exposure was laboured respiration. The 96-hour LC50 is >100 mg a.s./L (585 mg formulation/L, based on 17.1% w/w) .

Conclusion

96-hour LC50 >100 mg a.s./L.

Guidelines and limitations

The study is acceptable.

STUDY IIIA, 10.2.2.1/02

Characteristics

reference	:	[redacted]. (2011k)	species	:	Common carp (*Cyprinus carpio*)
type of study	:	Acute toxicity study	exposure duration	:	96 hours
year of execution	:	2011	nominal concn.	:	100 mg a.s./L

a.s. content	:	17.1 % w/w (201.0 g/L) BYI 02960			

Methods

A 96-hour acute toxicity limit test in juvenile carp (*Cyprinus carpio*) (2 replicates of 15 fish, not fed for 48 hours prior to testing) was conducted under static conditions with BYI 02960 SL 200 G (SL formulation, 17.1 % w/w (201.0 g/L) BYI 02960) at a nominal test concentration of 100 mg a.s./L. The test included an untreated control, tested also in 2 replicates of 15 fish each. The concentrations of

BYI 02960 were analytically confirmed by a sufficiently validated LC-MS/MS method in samples of all test solutions taken at the start, after 48 hours and at the end of exposure.

Results

The measured concentrations were in the range 97-106% of nominals at the start, after 48 hours and at the end of exposure. Test endpoints were based on nominal concentrations which is acceptable. Water quality parameters (pH, oxygen concentration and temperature) were in accordance with the OECD 203 guideline. No control and treated fish died, and no clinical sign were observed. The 96-hour LC50 is >100 mg a.s./L (585 mg formulation/L, based on 17.1% w/w).

Conclusion

96-hour LC50 >100 mg a.s./L.

Guidelines and limitations

The study is acceptable.

STUDY IIIA, 10.2.2.2/01

Characteristics

reference	:	Riebschläger T. (2010)	species	:	*Daphnia magna*
type of study	:	Acute toxicity study	exposure duration	:	48 hours
year of execution	:	2010	nominal concn.	:	62.5, 125, 250, 500 and 1000 mg product/L
GLP statement	:	Yes	dosing method	:	Static; direct addition to test water
guideline	:	OPPTS 850.1010, EEC C.2, OECD 202	acceptability	:	Acceptable
test substance	:	BYI 02960 SL 200 G (200 g/L SL formulation), batch 2010-001067	48 h-EC50	:	684 mg product/L (117 mg a.s./L)
a.s. content	:	17.1 % w/w			

Methods

A 48-hour acute toxicity test in *Daphnia magna* (<24 h old, 6 replicates of five daphnia each for each of the treatments and the control) was conducted under static conditions with BYI 02960 SL 200 G (SL formulation, 17.1 % w/w BYI 02960) at nominal test concentrations of 62.5, 125, 250, 500 and 1000 mg product/L. The test included an untreated control. The concentrations of BYI 02960 were analytically confirmed by a sufficiently validated LC-MS/MS method in samples of all test solutions taken at the start and end of exposure.

Results

The measured concentrations were in the range 99-110% of nominal at the start and end of exposure. Test endpoints were based on nominal concentrations which is acceptable. Water quality parameters (pH, oxygen concentration and temperature) were in accordance with the OECD 202 guideline. No mortality and signs of intoxication were observed in the control. At nominal test concentrations of 62.5, 125, 250, 500 and 1000 mg product/L, respectively, immobility after 48 hours was 0%, 6.7%, 30%, 33% and 63%. The 48-hour EC50 was 684 mg product/L, equivalent to 117 mg a.s./L.

Conclusion

48-hour EC50 684 mg product/L (117 mg a.s./L).

Guidelines and limitations

The study is acceptable.

STUDY IIIA, 10.2.2.3/01

Characteristics

reference	:	Bruns E. (2010b)			
type of study	:	Algae growth inhibition	species	:	*Pseudokirchneriella subcapitata*
year of execution	:	2010	exposure duration	:	72 hours
GLP statement	:	Yes	nominal concn.	:	49.4, 74.1, 111, 167 and 250 mg product/L
guideline	:	OECD 201 (2006)	dosing method	:	Static; stock solution in test water
test substance	:	BYI 02960 SL 200 G (200 g/L SL formulation), batch 2010-001067	acceptability	:	Acceptable
a.s. content	:	17.1 % w/w	72h-ErC50 & EyC50	:	>250 mg product/L (>42.8 mg a.s./L)

Methods

A 72-hour toxicity test on green algae (*Pseudokirchneriella subcapitata*) (3 replicates for each of the treatments and 6 replicates for the untreated control, each containing 1 x 10^4 cells/mL at the start) was conducted with BYI 02960 SL 200 g/L (SL formulation, 17.1 % w/w BYI 02960) at test concentrations of 49.4, 74.1, 111, 167 and 250 mg product/L. The concentrations of BYI 02960 were analytically confirmed by a sufficiently validated LC-MS/MS method in samples of all test solutions taken at the start and end of exposure.

Results

The measured concentrations were in the range 101-107% of nominal at the start and end of exposure. Test endpoints were based on nominal concentrations, which is acceptable. Physico-chemical parameters were in accordance with the OECD 201 guideline. The mean growth factor in the controls was 70 within 72 hours. The mean CV of the section-by-section specific growth rates in the control was 20%. The CV of the average specific growth rate in the control during the 72-hour period was 0.4%. Hence the validity criteria of OECD 201 (2006) were satisfied. The % inhibition range for specific growth rate and yield (% inhibition for yield not reported, but calculated by zRMS), respectively, were in the range -0.3 to 1.1% and -1.3 to 4.7%. The 72-h ErC50 and EyC50 was >250 mg product/L equivalent to >42.8 mg a.s./L.

Conclusion

72-h ErC50 and EyC50 >250 mg product/L (>42.8 mg a.s./L).

Guidelines and limitations

The study is acceptable.

B.9.2.2 Chronic toxicity

B.9.2.2.1 Laboratory testing (IIA 8.2.2; IIA 8.2.4; IIA 8.2.5; IIA 8.3.2; IIA 8.5.2; IIA 8.11)

STUDY IIA, 8.2.4/01

Characteristics

reference	:	[redacted]. (2011)	water solubility	:	3000-3200 mg/L at pH 4-9 & 20°C
type of study	:	Chronic toxicity study (ELS)	species	:	Fathead minnow (*Pimephales promelas*)
year of execution	:	2010	exposure duration	:	35 days
GLP statement	:	Yes	nominal concn.	:	0.625, 1.25, 2.5, 5 and 10 mg a.s./L
guideline	:	FIFRA 72-4, OPPTS 850.1400, OECD 210	dosing method	:	Flow-through; stock solution in DMF
test substance		BYI 02960 technical, batch 2009-000239	acceptability	:	Acceptable
purity	:	96.2%	NOEC	:	4.41 mg a.s./L

Methods

A 35-day fish early life stage flow-through study was undertaken with fathead minnow. Newly fertilised eggs (<24 hours post fertilisation, four replicate glass vessels with 35 eggs each per concentration) were exposed to BYI 02960 technical at test concentrations of 0.625, 1.25, 2.5, 5 and 10 mg a.s./L, with untreated and solvent control (DMF, 0.1 mL/L). On test day 5, when at least 90% of all viable control eggs had hatched, alevin were thinned to 20 per replicate. The total duration of the exposure period was 35 days. Samples for analytical confirmation of test concentrations using a sufficiently validated LC-MS/MS method were taken on day 0 and thereafter once weekly from selected replicates, with additional measurements on day 15 and 22. Hatching, mortality and fish behaviour was observed daily, and fish length and dry weight were measured at the end of the test.

Results

The mean measured concentrations of BYI 02960 technical were 0.619, 1.11, 2.05, 4.41 and 8.40 mg a.s./L, with limited and acceptable variation between replicates and time points. During the test, the pH was in the range 7.6-8.0, the oxygen concentration was 76-98% of the saturation value, and the temperature was in the range 24.6-25.0. In all treatments and the controls, hatch started on day 3. Other biological results are summarised in the table below. The observations of scoliosis and being at the water surface were infrequent, did not represent a dose-relationship and are considered to be unrelated to the treatment. The only adverse treatment related effect was reduced larval survival at the highest concentration. The reduced larval survival at 0.619 mg a.s./L is considered to be unrelated to the treatment in the absence of a dose-relationship. The NOEC is 4.41 mg a.s./L.

Table B.9.2.2.1-01 Results of an Early-Life-Stage test on fathead minnow (*Pimephales promelas*) with BYI 02960 technical

* Significantly different from control at 5% level

Conclusion

NOEC 4.41 mg a.s./L.

Guidelines and limitations

The study is acceptable.

STUDY IIA, 8.3.2.1/01

Characteristics

reference	:	Riebschläger T. (2011)	water solubility	:	3000-3200 mg/L at pH 4-9 & 20°C
type of study	:	Chronic toxicity study	species	:	*Daphnia magna*
year of execution	:	2011	exposure duration	:	21 days
GLP statement	:	Yes	nominal concn.	:	0.8, 1.6, 3.2, 6.4, 12.8 and 25.6 mg a.s./L
guideline	:	EPA 72-4, OPPTS 850.1300, EEC C.20, OECD 211	dosing method	:	Semi-static; stock solution in DMF
test substance	:	BYI 02960 technical, batch BYI02960-01-03 (original batch 2009-000239)	acceptability	:	Acceptable
purity	:	96.2%	21-day NOEC	:	3.2 mg a.s./L

Methods

A 21-day chronic reproductive toxicity test in *Daphnia magna* (<24 h old, 10 replicates with one daphnia each per concentration) was conducted according to OECD 211 under semi-static conditions (renewal every 2-3 days) with BYI 02960 technical at nominal test concentrations of 0.8, 1.6, 3.2, 6.4, 12.8 and 25.6 mg a.s./L, with untreated control and solvent control (0.1 mL/L DMF). The concentrations of BYI 02960 were analytically confirmed by a sufficiently validated HPLC-MS/MS method in samples of all fresh test solutions of day 0, 9 and 19 and in the corresponding aged solutions. Endpoints reported were parent mortality, total number of offspring per parent animal, parent age at first offspring emergence, neonates behaviour and length and dry weight of parent daphnia at the end of the test.

Results

The measured concentrations of BYI 02960 were 102-109% of nominal in fresh solutions and 102-117% in the corresponding aged solutions. Test endpoinst were based on nominal concentrations,

which is acceptable. Water quality parameters and the number of offspring in the controls were in accordance with the requirements of the OECD 211 guideline.

No sublethal effects were observed in neonates. The remaining biological results are summarised in the Table below. Treatment related statistically significant adverse effects were recorded on reproduction, as measured by the cumulative number of offspring per living female, at and above 12.8 mg a.s./L and on growth (body length) at and above 6.4 mg a.s./L, whereas body mass was statistically significantly reduced at the highest concentration of 25.6 mg a.s./L only. The NOEC is 3.2 mg a.s./L.

Table B.9.2.2.1-02 Summary of biological results of 21-day Daphnia reproduction test with BYI 02960 technical

nominal concentration (mg a.s./L)	parent mortality (%)	total offspring per living parent	parent age at first offspring emergence (d)	body length (mm)	body dry mass (mg)
Control	0	126.1	9.1	4.5	0.97
solvent control	0	126.2	9.4	4.6	0.98
0.80	0	132.8	9.0	4.5	0.97
1.6	0	122.3	9.2	4.4	0.89
3.2	0	121.2	9.4	4.4	0.83
6.4	0	107.7	9.3	4.3*	0.98
12.8	0	102.8*	9.6	4.2*	0.83
25.6	0	85.4*	9.6	3.9*	0.63*

* Statistically significant at 5% level

A study with the reference item potassium dichromate was performed about 4 months earlier and gave a 24-h EC50 of 1.0 mg/L, which is acceptable (OECD 202 (2004): 0.6-2.1 mg/L).

Conclusion

NOEC 3.2 mg a.s./L.

Guidelines and limitations

The study is acceptable.

STUDY IIA, 8.3.2.1/02

Characteristics

reference	:	Riebschläger T. (2012)	water solubility	:	No data
type of study	:	Chronic toxicity study	species	:	*Daphnia magna*
year of execution	:	2011	exposure duration	:	21 days
GLP statement	:	Yes	nominal concn.	:	3.5, 8.1, 18.7, 43.3 and 100 mg pure metabolite/L
guideline	:	EPA 72-4, OPPTS 850.1300, EEC C.20, OECD 211	dosing method	:	Semi-static; direct addition to test water
test substance	:	BYI 02960-succinamide; batch BCS-CR74729-01-01 (original batch number BCOO 6329-2-10)	acceptability	:	Acceptable
purity	:	97.8%	21-day NOEC	:	43.3 mg pure metabolite/L

Methods

A 21-day chronic reproductive toxicity test in *Daphnia magna* (<24 h old, 10 replicates with one daphnia each per concentration) was conducted according to OECD 211 under semi-static conditions (renewal every 2-3 days) with BYI 02960-succinamide (metabolite of BYI 02960) at nominal test concentrations of 3.5, 8.1, 18.7, 43.3 and 100 mg pure metabolite/L, with untreated control. The test solutions were prepared by direct addition of the test material to the test water. The concentrations of BYI 02960-succinamide were analytically confirmed by a sufficiently validated HPLC-UV method in samples of all fresh test solutions of day 0, 9 and 19 and in the corresponding aged solutions. Endpoints reported were parent mortality, total number of offspring per parent animal, parent age at first offspring emergence, neonates behaviour and length and dry weight of parent daphnia at the end of the test.

Results

The measured concentrations of BYI 02960-succinamide were 103-111% of nominal in fresh solutions and 104-109% in the corresponding aged solutions. Test endpoints were based on nominal concentrations, which is acceptable. Water quality parameters and the number of offspring in the controls were in accordance with the requirements of the OECD 211 guideline.

No sublethal effects were observed in neonates. The remaining biological results are summarised in the Table below. The only treatment related statistically significant adverse effect was an increase of parent age at first offspring emergence at the highest test concentration of 100 mg pure metabolite/L. Based on this finding, the NOEC is 43.3 mg pure metabolite/L.

Table B.9.2.2.1-02 Summary of biological results of 21-day Daphnia reproduction test with BYI 02960-succinamide

nominal concentration (mg pure metabolite/L)	parent mortality (%)	total offspring per living parent	parent age at first offspring emergence (d)	body length (mm)	body dry mass (mg)
control	0	104.9	9.0	4.3	0.97
3.5	0	101.9	9.1	4.2	0.86

18.7	0	90.0	9.0	4.2	0.91
43.3	0	98.5	9.0	4.3	0.83
100	0	90.6	9.7*	4.2	0.90

* Statistically significant at 5% level

The most recent study with the reference item potassium dichromate gave a 24-h EC50 of 0.87 mg/L, which is acceptable (OECD 202 (2004): 0.6-2.1 mg/L).

Conclusion

NOEC 43.3 mg pure metabolite/L.

Guidelines and limitations

The study is acceptable.

STUDY IIA, 8.3.2.2/01

Characteristics

reference	:	Bruns E. (2011g)	water solubility a.s.	:	3000-3200 mg/L at pH 4-9 & 20°C
type of study	:	Chronic toxicity study	species	:	*Chironomus riparius*
year of execution	:	2010	exposure duration	:	28 days
GLP statement	:	Yes	nominal concn.	:	1.25, 2.50, 5, 10, 20 and 40 µg a.s./L
guideline	:	OECD 219	dosing method	:	Static (spiked water)
test substance	:	BYI 02960; technical, batch 2009-000239	acceptability	:	Acceptable
a.s. content	:	96.2%	28-day NOEC	:	~~10~~ 6.81 µg a.s./L (based on mean measured concentrations).

Methods

The chronic toxicity of BYI 02960 technical to *Chironomus riparius* (2-3 days old, 1st instar larvae) was assessed in a 28-day water/sediment system under static conditions using the spiked water method. The test was performed in 0.6 L glass beakers, with four replicates for each test concentration and the solvent control. The beakers were filled with 140 g wet sediment (artificial OECD 219 soil: 75.8% quartz sand, 4% peat (measured organic carbon content 2.0%), 20% kaolinite clay, 0.2% calcium carbonate) and 380 mL (about 6 cm) of overlying water, 7 days prior to treatment. Twenty midge larvae were added to each beaker one day prior to treatment. The water was gently aerated during the test, except for 24 hours following addition of the midges. On day 0, the test water was spiked just below the surface with an aliquot of a stock solution of the test substance in DMF, to provide nominal test concentrations of 1.25, 2.50, 5, 10, 20 and 40 µg a.s./L, with solvent control (0.1 mL/L DMF). Additional replicates were set up for analytical measurements on overlying water and pore water on day 0 (1 hour after treatment), 7 and 28 after treatment. Water samples were analysed by HPLC-MS/MS using a sufficiently validated method. Behaviour, mortality and emergence of the midges were monitored until test end.

Results

The measured concentrations of BYI 02960 in the overlying water were in the range 85-110% (mean 99%), 37-83% (mean 60%) and 30-52% (mean 41%) of nominal, after 1 hour, 7 days and 28 days, respectively. The measured concentrations of BYI 02960 in the porewater were in the range 0.4-1.0% (mean 0.6%), 1.0-3.0% (mean 2.0%) and 1.4-2.9% (mean 2.2%) of nominal, after 1 hour, 7 days and 28 days, respectively. No measurements were done in the sediment. The test endpoints were based on nominal concentrations, which was considered acceptable by the RMS in the original DAR. However, during pesticide peer review meeting 124 in December 2014, it was agreed that the endpoints for chironomus should be expressed in terms of mean measured concentration in the water column when the analytical measurement concentrations are outside of the range 80-120% and when concentrations in the sediment are not available.

The biological test results are summarised in the Table below. Water quality parameters were in accordance with the OECD 219 guideline. All validity criteria of the OECD 219 guideline concerning

emergence in the control and physico-chemical conditions during the test were satisfied. No emergence occurred at 40 µg a.s./L (nom.) / 29.8 µg a.s./L (m.m.). Treatment related statistically significant adverse effects on emergence and development rate were recorded at 20 µg a.s./L (nom.) / 15.4 µg a.s./L (m.m.). The NOEC was 10 µg a.s./L (nom.) / 6.81 µg a.s./L (m.m.).

Table B.9.2.2.1-03 Summary of biological results of 28-day chronic toxicity test with BYI 02960 technical on *Chironomus riparius*

nominal conc. (µg a.s./L)	geom. mean measured conc. (µg a.s./L)	emergence rate (%)	development rate (1/d)
solvent control	solvent control	90.0	0.058
1.25	0.679	87.5	0.058
2.5	1.25	92.5	0.057

40	29.8	0	0

* Statistically significant at 5% level

Conclusion

NOEC ~~10~~ 6.81 µg a.s./L (based on mean measured concentrations).

Guidelines and limitations

The study was performed according to OECD 219 (2004) and is acceptable.

STUDY IIA, 8.3.2.2/02

Characteristics

reference	:	Bruns E. (2011h)	water solubility a.s.	:	No data
type of study	:	Chronic toxicity study	species	:	*Chironomus riparius*
year of execution	:	2011	exposure duration	:	28 days
GLP statement	:	Yes	nominal concn.	:	100 mg pure metabolite/L
guideline	:	OECD 219	dosing method	:	Static (spiked water)
test substance	:	sodium difluoroacetate; batch BCS-AB60841-01-01 (original batch number BCOO 6092-3-1)	acceptability	:	Acceptable
a.s. content	:	99.0%	28-day NOEC	:	100 mg pure metabolite/L

Methods

The chronic toxicity of sodium difluoroacetate (metabolite of BYI 02960 technical) to *Chironomus riparius* (2-3 days old, 1st instar larvae) was assessed in a 28-day water/sediment system under static conditions using the spiked water method. The test was performed in 0.6 L glass beakers, with six replicates for the test concentration and the control. The beakers were filled with 140 g wet sediment (artificial OECD 219 soil: 75.0% quartz sand, 4% peat (measured organic carbon content 2.1%), 20% kaolinite clay, 0.1% calcium carbonate) and 380 mL (about 6 cm) of overlying water, 7 days prior to treatment. Twenty midge larvae were added to each beaker one day prior to treatment. The water was gently aerated during the test, except for 24 hours following addition of the midges. On day 0, the test water was spiked just below the surface with an aliquot of a stock solution of the test substance in test

water, to provide the nominal test concentration of 100 mg pure metabolite/L, with untreated control. Additional replicates were set up for analytical measurements on overlying water and pore water on day 0 (1 hour after treatment), 7 and 28 after treatment. Water samples were analysed by HPLC-MS/MS using a sufficiently validated method. Behaviour, mortality and emergence of the midges were monitored until test end.

Results

The measured concentrations of sodium difluoroacetate in the overlying water were 105%, 95.1% and 98.3% of nominal, after 1 hour, 7 days and 28 days, respectively. The test endpoints were based on nominal concentrations, which is acceptable. The measured concentrations of sodium difluoroacetate in the porewater were 1.55%, 6.61% and 7.95% of nominal, after 1 hour, 7 days and 28 days, respectively.

The biological test results are summarised in the Table below. Water quality parameters were in accordance with the OECD 219 guideline. All validity criteria of the OECD 219 guideline concerning emergence in the control and physico-chemical conditions during the test were satisfied. No treatment related statistically significant adverse effects on emergence and development rate were recorded at 100 mg pure metabolite/L. The NOEC was 100 mg pure metabolite/L.

Table B.9.2.2.1-04 Summary of biological results of 28-day chronic toxicity test with sodium difluoroacetate on *Chironomus riparius*

nominal conc. (mg pure metabolite/L)	emergence rate (%)	development rate (1/d)
Control	95.8	0.062
100	90.0	0.063

Conclusion

NOEC 100 mg pure metabolite/L.

Guidelines and limitations

The study was performed according to OECD 219 (2004) and is acceptable.

Methods

The chronic toxicity of 6-chloronicotinic acid (6-CNA = IC-0, metabolite of BYI 02960) to *Chironomus riparius* (2-3 days old, 1st instar larvae) was assessed in a 28-day water/sediment system under static conditions using the spiked water method. The test was performed in 0.6 L glass beakers, with six replicates for the test concentration and the control. The beakers were filled with 140 g wet sediment (artificial OECD 219 soil: 75.0% quartz sand, 4% peat (measured organic carbon content 2.1%), 20% kaolinite clay, 1% calcium carbonate) and 380 mL (about 6 cm) of overlying water, 7 days prior to treatment. Twenty midge larvae were added to each beaker one day prior to treatment. The water was gently aerated during the test, except for 24 hours following addition of the midges. On day 0, the test water was spiked just below the surface with an aliquot of a stock solution of the test substance in test water, to provide the nominal test concentration of 100 mg pure metabolite/L, with untreated control. Additional replicates were set up for analytical measurements on overlying water and pore water on day 0 (1 hour after treatment), 7 and 28 after treatment. Water samples were analysed by HPLC-MS/MS using a sufficiently validated method. Behaviour, mortality and emergence of the midges were monitored until test end.

Results

The measured concentrations of 6-chloronicotinic acid in the overlying water were 102%, 89.6% and 90.6% of nominal, after 1 hour, 7 days and 28 days, respectively. The test endpoints were based on nominal concentrations, which is acceptable. The measured concentrations of 6-chloronicotinic acid in the porewater were in 1.29%, 6.66% and 7.29% of nominal, after 1 hour, 7 days and 28 days, respectively.

The biological test results are summarised in the Table below. Water quality parameters were in accordance with the OECD 219 guideline. All validity criteria of the OECD 219 guideline concerning emergence in the control and physico-chemical conditions during the test were satisfied. No treatment related statistically significant adverse effects on emergence and development rate were recorded at 100 mg pure metabolite/L. The NOEC was 100 mg pure metabolite/L.

STUDY IIA, 8.11.1/04

Characteristics

reference	:	Claude M.B. *et al.* (2011)	water solubility	:	3000-3200 mg/L at pH 4-9 & 20°C
type of study	:	Life cycle toxicity study (marine organism)	species	:	Saltwater mysid (*Mysidopsis bahia*)
year of execution	:	2010-2011	exposure duration	:	28 days
GLP statement	:	Yes	nominal concn.	:	4.6, 8.0, 13.9, 24.2 and 42 µg a.s./L
guideline	:	OPPTS 850.1350	dosing method	:	Flow through; stock solutions in DMF
test substance	:	BYI 02960 technical, batch BYI 2009-02960-01-03	acceptability	:	Acceptable
purity	:	96.2%	NOEC	:	13.2 µg a.s./L

Methods

A 28-day life-cycle toxicity test on juveniles (<24 h old) of the saltwater mysid *Mysidopsis bahia* was conducted under flow-through conditions with BYI 02960 technical at test concentrations of 4.6, 8.0, 13.9, 24.2 and 42 µg a.s./L. The test included untreated and solvent controls (0.1 mL/L DMF). The test was initiated with <24-h old juveniles (4 replicate chambers with 15 neonate mysids each for each concentration and the controls). On day 14 of the test, after mysids attained sexual maturity, male and female adults were paired in each treatment and control group, with a maximum of five reproductive pairs per replicate. Reproduction of the paired mysids was monitored through termination on day 28. Observations for mortality and signs of toxicity were conducted daily throughout the test. At test termination, the total body lengths and dry weights of all surviving first-generation mysids were measured. The concentrations of BYI 02960 were analytically confirmed by a sufficiently validated HPLC/UV method in samples of all test solutions taken at the start of the test, weekly during the test and at test termination.

Results

The measured concentrations were in the range 76-103% of nominals. Test endpoints were based on mean measured concentrations (4.2, 7.8, 13.2, 23.6 and 40 µg a.s./L). Water quality parameters (pH, oxygen concentration, temperature and salinity) were in accordance with the OPPTS 850.1350 guideline (pH 7.9-8.1, dissolved oxygen ≥5.0 mg/L(≥68% of saturation), 24.5-26.4°C, salinity 19-21 $^{0}/_{00}$). No treatment related signs of intoxication were observed in any of the treatments. No treatment related mortality was observed in any treatment, and at test termination there were no biologically relevant and statistically significant differences in body length and dry weight between the treated groups and the controls. The results for reproduction are summarised in the Table below.

Table B.9.2.2.1-06 Reproductive results of 28-day life cycle toxicity test with BYI 02960 technical on *Mysidopsis bahia*

Treatment (µg a.s./L)	no. of young/reproductive day	
	mean	standard deviation
negative control	0.396	0.119
solvent control	0.450	0.167
pooled control	0.423	0.137
4.2	0.358	0.250

7.8	0.267	0.145
13.2	0.240	0.090
23.6	0.156*	0.157
40	0.173*	0.113

** Statistically significant difference from control at 5% uncertainty level.*

At 4.2, 7.8, 13.2, 23.6 and 40 µg a.s./L, respectively, reproduction was reduced by 15, 37, 43, 63 and 59%, relative to the pooled control. The difference from the pooled control was statistically significant at the two highest test concentrations. The high variability of reproduction (see standard deviations in Table above) is associated with the test design, where total reproduction per replicate of 5 pairs is determined. Based on statistical significance, the NOEC concluded by the author of the report was 13.2 µg a.s./L. However, biological relevance should also be taken into consideration. The replicate mean reproduction in the controls was in the range 0.261-0.661 young per reproductive day. At 4.2 µg a.s./L (mean reproduction reduced by 15%), replicate mean reproduction was in the range 0.102-0.600 young per reproductive day, and 2 of 4 replicate means were below the control range. At 7.8 µg a.s./L (mean reproduction reduced by 37%), replicate mean reproduction was in the range 0.107-0.415 young per reproductive day, and 2 of 4 replicate means were below the control range. At 13.2 µg a.s./L (mean reproduction reduced by 43%), replicate mean reproduction was in the range 0.169-0.369 young per reproductive day, and 3 of 4 replicate means were below the control range. Based on the fact that there is a concentration-related trend in effects on reproduction, that at 7.8 and 13.2 µg a.s./L reproduction was reduced by 37-43% relative to the pooled control, and that reproduction in 2-3 out of 4 replicates was below the control range, it was proposed by the RMS to set the NOEC at 4.2 µg a.s./L. In response to this proposal, the applicant submitted two statements (Springer T, 2013, BCS doc M-452382-01-1; Bruns *et al.*, 2013, BCS doc M-452374-01-1). These statements are summarised below.

Statement by Springer (2013)

Springer (2013) suggested that the decision to designate 4.2 µg a.i./L as the NOEC might be related to current discussions on using EC10 values as a surrogate for the NOEC. The mean reproduction rate in the pooled controls was 0.423 offspring/female/day, with 95% confidence limits of 0.128 to 0.627. Based on this confidence interval, the smallest change in reproduction that can dependably be shown to be a decrease relative to the pooled controls is approximately 30% (i.e. 100-100*0.128/0.423). When using the value of 0.128 offspring/female/day as the within-group standard deviation during power analysis (based on 4 replicates and a type I error rate of 0.05), the smallest effect size that could be detected with a power of 0.8 is approximately a 73 % difference between the control and treatment group. Springer (2013) stated that this power is far less than is desirable, and indicates that that small changes in mysid reproduction cannot be dependably assessed using the standard experimental design described in test guideline. Springer also noted that the pooled control mean was strongly influenced by a single replicate from the solvent control, where reproduction had an unusually high value of 0.66.

Statement by Bruns et al. (2013)

Bruns *et al.* (2013) stated that "*the mean value of the solvent control has been dramatically impacted by an extraordinary high reproduction of one single breeding pair. The number of 29 young per reproductive female observed for this single breeding pair in the solvent control appears to be inconsistently high considering that the next highest value is 16 young per breeding pair. The fact that this value was extraordinary was checked by BCS using the control data of the 10 last mysid studies available in the BCS electronically archiving system DART. In none of the evaluated studies a control breeding pair produced 29 young within 14 reproduction days. Hence it is reasonable to exclude this number from the evaluation.*" The results excluding this single breeding pair are summarised in the Table below.

Table B.9.2.2.1-07 Reproductive results of 28-day life cycle toxicity test with BYI 02960 technical on *Mysidopsis bahia* (excluding outlier in solvent control)

Mean Measured Concentration (µg a.i./L)	Mean Number of Young Produced Per Reproductive Day ± SD	Mean Percent of Surviving Females Producing Young[1]	Mean Number of Young Per Surviving Female ± SD[1]
Negative Control	0.396 ± 0.119	100	5.2 ± 1.54
Solvent Control[2]	0.352 ± 0.105	85.0	4.6 ± 1.36
Pooled Control[2]	0.374 ± 0.106	92.3	4.9 ± 1.38
4.2	0.358 ± 0.250	92.9	4.9 ± 3.76
7.8	0.267 ± 0.145	88.9	3.5 ± 1.89
13.2	0.240 ± 0.090	77.8	3.1 ± 1.16
23.6	0.156 ± 0.157*	47.1**	2.1 ± 2.02*
40	0.173 ± 0.113*	50.0**	2.3 ± 1.47*

* Statistically significant decrease in reproduction and mean number of young per surviving female in comparison to the pooled control using Dunnett's test ($p \leq 0.05$).
** Statistically significant decrease in percent of surviving females producing young in comparison to the pooled control using Fisher's Exact test ($p \leq 0.05$).
[1] Calculated based on the total number of surviving females present at test termination. Females that died prior to test termination and the young that they produced were excluded from the calculation of the mean percent of females producing young and the mean number of young per female.
[2] One female in compartment 3, replicate D of the Solvent Control group had an inconsistently high number of young (the female produced 29 mysids whereas the next closest amount produced from a female out of the entire test was 16 young). Therefore, the data from this female was excluded and the statistics were reanalyzed.

Bruns *et al.* (2013) further argued that the discriminatory power of the chronic mysid shrimp study especially for the endpoint 'reproduction' is hampered by the natural high biological variability of this endpoint. BCS performed additional statistics of the data set by evaluating the endpoint 'reproduction' on the basis of the single breeding pairs instead of using the mean values for the replicates. This approach is covering the entire biological variation as observed for the single breeding pairs. The data set was used to calculate EC30 values as well as the corresponding confidence limits where possible. The EC30 was used due to the known standard deviation of control data as well as taking the statement of Springer (2013) into consideration. The results are summarised in the Table below. Bruns *et al.* concluded that all calculated EC30 values are slightly above the originally reported NOEC of

13.2 µg/L, and that in all cases the NOEC of 13.2 µg/L was within the calculated confidence limits of the EC30 values.

Table B.9.2.2.1-08 EC_{30} calculations based on the 10 previous control data sets (excluding outlier in solvent control)

Data used for calculation	EC_{30}	R^2	P(F)	Lower 95% confidence limit	Upper 5% confidence limit
Historical control data of 10 previous studies - Probit	17.8 µg/L	0.74	0.061	-	-
Historical control data of 10 previous studies plus data minus concentration 40 µg/L - Probit	15.4 µg/L	0.96	0.019	10.6 µg/L	19.7 µg/L
Historical control data of 10 previous studies plus data minus concentration 40 µg/L - Logit	15.7 µg/L	0.97	0.018	10.9 µg/L	19.6 µg/L
Historical control data of 10 previous studies plus data minus concentration 40 µg/L - Weibull	16.1 µg/L	0.97	0.016	11.3 µg/L	19.5 µg/L

The coefficient of determination, r^2 ($0 <= r^2 <= 1$), gives the proportion of variance explained by the dose/response function.
if p(F) <= alpha, the selected significance level, (e.g., alpha = 0.05) the regression revealed significant results (= slope is significantly different from zero).

Bruns *et al.* presented historical control data from 10 chronic mysid studies available to the applicant (including those of the present study). Based on this control data, Bruns *et al.* concluded that 30% difference to the control mean value for the endpoint 'reproduction' is not a clear effect as the controls are varying by about ±30%. Bruns *et al.* stated that the most important points which were concluded on the basis of this data are:

- The number of young per female is extremely variable: 0 – 45 young per female within 12-17 reproductive days.
- Number of Young produced per female and reproduction day ranges from 0 to 2.65
- The system is resulting in LOEC's which are ranging between 33 to 93% inhibition compared to controls
- The NOECs are ranging between -19 to 43% difference compared to the controls
- The concentrations below and including the NOEC range between -38.7 up to 47.3% difference compared to the controls.

Bruns *et al.* (2013) stated that this evaluation underpins the observation that the endpoint 'reproduction' is highly variable.

Lastly, Bruns *et al.* (2013) gave the following additional arguments supporting their case:

- The chronic mysid shrimp study is a problematic test system. In frequent cases studies have to be performed several times before a valid test (according to guideline recommendations) is available.
- The observed NOEC, as presented in the original report, is fulfilling the validity criteria for controls according to OPPTS 850.1350. This gives further support to the reliability of the presented NOEC of 13.2 µg/L.

Evaluation of statements by RMS

It is agreed that the solvent control breeding pair with 29 young per reproductive female is an outlier and may be eliminated from the data (although there was one breeding pair in the historical control data that produced an even higher number of 45 young in 17 reproduction days). The RMS performed a Dixon's outlier test on this data of 29 young per reproductive female using the reported results for 20 breeding pairs in the solvent control, and this gave a Q-value of 0.552, which is higher than the statistical Q value of 0.401 for n=20. Hence this test confirmed that the data for this breeding pair are exceptionally high and may be removed prior to statistical analysis. The evaluation below is based on data excluding this outlier. When excluding this outlier, at 4.2, 7.8, 13.2, 23.6 and 40 µg a.s./L, reproduction (expressed as mean number of young produced per reproductive day) was reduced by -3%, 29%, 33%, 62% and 52% relative to the pooled control. Statistical significance (5% uncertainty level) was reached only at the two highest concentrations. Since the reductions at 7.8 and 13.2 µg a.s./L (29-33%) were approximately equal to the relative standard deviation in the control (30%) and the solvent control (30%), it is insufficiently certain that the reductions of 29-33% at 7.8 and 13.2 µg a.s./L are a treatment related effect. Hence the NOEC may be set at 13.2 µg a.s./L.

The submitted historical control data originated from 3 different laboratories, and only 4 studies (inlcuding the present study) were performed at Wildlife. The studies were conducted between 1996 and 2008, whereas the present study was performed in 2011. Historical control data should preferably be recent data from the same laboratory where the study is performed. Therefore the use of the combined historical control data from all ten studies in EC30 estimations is considered to be a questionable procedure. However, these control data confirm the high variability of the reproduction rate: the relative standard deviation of the reproduction rate in 14 controls (4 studies had controls and solvent controls) was in the range of 5-73%, with a mean of 25%.

Conclusion

NOEC 13.2 µg a.s./L.

Guidelines and limitations

The study is acceptable. Comments on the interpretation of the study results were incorporated in the above summary. The conclusion as stated above is acceptable.

STUDY IIIA, 10.2.6.2/01

Characteristics

Reference	:	Silke G. (2011)	species	:	*Chironomus riparius*
type of study	:	Chronic toxicity study	exposure duration	:	28 days
year of execution	:	2011	nominal concn.	:	1.50, 3.00, 6.00, 12.0, 24.0 and 48.0 µg a.s./L
GLP statement	:	Yes	dosing method	:	Static (spiked water)
Guideline	:	OECD 219	acceptability	:	Acceptable
test substance	:	BYI 02960 SL 200 G (200 g/L SL formulation), batch 2010-001067	28-day NOEC	:	~~12.0~~ 9.89 µg a.s./L (based on mean measured concentrations).
a.s. content	:	17.1 % w/w (201.0 g/L) BYI 02960			

Methods

The chronic toxicity of BYI 02960 SL 200 G (SL formulation, 17.1 % w/w (201.0 g/L) BYI 02960) to *Chironomus riparius* (2-3 days old, 1st instar larvae) was assessed in a 28-day water/sediment system under static conditions using the spiked water method. The test was performed in 0.6 L glass beakers, with four replicates for each test concentration and the untreated control. Seven days prior to treatment, the beakers were filled with 140 g wet sediment (artificial OECD 219 soil: 75.0% quartz sand, 4% peat (equivalent to 2.1% organic carbon), 20% kaolinite clay, 0.1% calcium carbonate) and 380 mL (about 6 cm) of overlying water. Twenty midge larvae were added to each beaker one day prior to treatment. The water was gently aerated during the test, except for 24 hours following addition of the midges. On day 0, the test water was spiked just below the surface with an aliquot of a stock solution of the test substance in test water, to provide nominal test concentrations of 1.50, 3.00, 6.00, 12.0, 24.0 and 48.0 µg a.s./L, with untreated control. Additional replicates were set up for analytical measurements on overlying water and pore water on day 0 (1 hour after treatment) and 7 (28 days after treatment analysis was performed on biological replicates). Water samples were analysed by HPLC-MS/MS using a sufficiently validated method. Behaviour, mortality and emergence of the midges were monitored until test end.

Results

The measured concentrations of BYI 02960 in the overlying water were in the range 101-112% (mean 109%), 78-84% (mean 81%) and 54-62% (mean 58%) of nominal, after 1 hour, 7 days and 28 days, respectively. The measured concentrations of BYI 02960 in the porewater were in the range 1.0-2.0% (mean 1.4%), 4.0-5.5% (mean 4.8%) and 3.5-4.7% (mean 4.1%) of nominal, after 1 hour, 7 days and 28 days, respectively. No measurements were done in the sediment. The test endpoints were based on nominal concentrations, which was considered acceptable by the RMS in the original DAR. However, during pesticide peer review meeting 124 in December 2014, it was agreed that the endpoints for chironomus should be expressed in terms of mean measured concentration in the water column when the analytical measurement concentrations are outside of the range 80-120% and when concentrations in the sediment are not available.

The biological test results are summarised in the Table below. Water quality parameters were in accordance with the OECD 219 guideline. All validity criteria of the OECD 219 guideline concerning emergence in the control and physico-chemical conditions during the test were satisfied. No emergence occurred at 48.0 µg a.s./L (nom.) / 38.0 µg a.s./L (m.m.). Treatment related statistically significant adverse effects on emergence and development rate were recorded at 24.0 µg a.s./L (nom.) / 20.1 µg a.s./L (m.m.). The NOEC was 12.0 µg a.s./L (nom.) / 9.89 µg a.s./L (m.m.).

Table B.9.2.2.3-01 Summary of biological results of 28-day chronic toxicity test with BYI 02960 SL 200 G on *Chironomus riparius*

Nominal conc. (µg a.s./L)	geom. mean measured conc. (µg a.s./L)	emergence rate (%)	development rate (1/d)
Control	solvent control	87.5	0.063
1.50	1.20	91.3	0.063

3.00	2.34	86.3	0.064
6.00	4.52	91.3	0.065

24.0	20.1	35.0*	0.051*
48.0	38.0	0	-

* Statistically significant at 5% level

Conclusion

~~12.0~~ 9.89 µg a.s./L (based on mean measured concentrations).

Guidelines and limitations

The study was performed according to OECD 219 (2004) and is acceptable.

B.9.2.3 Bioaccumulation (IIA 8.2.6.1)

MIII: BYI 02960 is a substance of low bioaccumulation potential due to the high water solubility (3 g/L) and low Log Pow (1.2). It can therefore be concluded that BYI 02960 is rapidly distributed in the water environment and the tendency for accumulation in biota will be low. Further testing of non-target species is therefore not justifiable.

B.9.2.4 Summary of aquatic toxicity data

Active substance and formulation

The active ingredient of BYI 02960 SL200, BYI 02960, has been tested on all laboratory indicator species for aquatic organisms representing all trophic levels of the aquatic environment. Acute data on fish toxicity are available for four different species, amongst them the sensitive cold water fish trout, and the salt water fish *Cyprinodon variegatus*. The results indicate that BYI 02960 is practically non-toxic to fish. As such, the LC50 values reported are greater than the highest concentration within the test. Using the formulated product BYI 02960 SL 200G the LC50 as related to the active substance was >100 mg a.i./L.

An early life-stage test for BYI 02960 confirms the low toxicity to fish also on chronic scale. Exposed continuously over the full developmental life-phase of fathead minnow a slightly reduced fry survival at the highest test concentration of 10 mg a.i./L was recorded. As compared to the untreated control survival was reduced by 7% resulting in an overall fry survival of 87.5% at a mean measured concentration of 8.4 mg a.i./L. Time to hatch and hatching success was not influenced, neither was any effect observed on growth as determined on length and weight.

A very selective non-target activity of BYI 02960 is further confirmed by low toxicity to representatives of three other taxonomic groups, namely amphibians, algae and aquatic plants. There were no adverse effects noted in the 48h acute frog test, and the influence of the active substance on *Pseudokirchneriella subcapitata* and *Lemna gibba* was also negligible. In a test with the formulation no effects on algal development were recorded at the highest test concentration used 250 mg

formulation/L corresponding to 42.5 mg a.i./L. For Lemna, an onset of effects was determined at a mean measured concentration of 67.7 mg a.i./L ; therefore aquatic plants are also considered to be insensitive to the active substance.
BYI 02960 is an insecticide against sucking insects. Hence, a side activity against aquatic invertebrates can be anticipated. Data were generated on all laboratory standard indicator species of aquatic arthropods: the cladoceran *Daphnia magna*, the midge *Chironomus riparius* and, the marine species *Americamysis bahia* and the mollusc *Crassostrea virginica*. The most sensitive organism for BYI 02960 was found to be *Chironomus riparius*. While acute toxicity to daphnids was negligible with a NOEC for the active substance at or greater than 77.6 mg a.i./L, the 50% effect concentration (EC50) to the midge was determined to be at a concentration of 0.062 mg a.i./L. For the saltwater species, the LC50 of the mysid shrimp was at 0.26 mg a.i./L and indicates as such a lower sensitivity than the insect. BYI 02960 was non-toxic to the marine oyster.
Chronic tests confirm the high toxicity of the active substance to *Chironomus riparius*. The lowest-observed-effect concentration (LOEC) impacting the emergence of the developed Chironomus larvae was at ~~0.02~~ 0.015 mg a.i./L, only a factor of ~~3~~ 4 below the acute EC50 values. The acute-to-chronic ratio for the most sensitive ecotoxicological endpoint, survival of Chironomus, for BYI 02960 is thus low. The immediate activity observed in the acute test appears to be reflected in the chronic test.
The 28 day chronic mysid shrimp test resulted in a LOEC of 0.0236 mg a.i./L based upon a statistically significant influence on reproductive output. The notifier considers that from the first-tier laboratory test species indicative for a potential effect of an insecticide, Chironomus is considered to be of higher relevance for the risk assessment than the marine shrimp as it reflects a real taxonomic group present in the freshwater biocoenosis. The influence of the formulation BYI 02960 SL 200 G was therefore examined on Chironomus as the most sensitive invertebrate. The lowest-observed-effect concentration was at ~~0.024~~ 0.020 mg a.i./L, the NOEC was established at ~~0.012~~ 0.00989 mg a.i./L. However, RMS does not accept to disregard the mysid shrimp data. Saltwater species are always included in the risk assessment unless a clear difference in sensitivity is observed between saltwater and freshwater species and it can be proven that exposure of saltwater environments is not relevant. In this case, the mysid shrimp NOEC is 0.0132 mg a.i./L and therefore close to the Chironomus endpoint. Hence, it is not considered acceptable to disregard the data available for the mysid shrimp. However, the Chironomus endpoint is driving the risk assessment since it is slightly lower.
In general, there was no relevant influence of the formulation on the toxicity in comparison to the toxicity with the active substance.

Accepted data on the acute toxicity of BYI 02960 (flupyradifurone) and BYI 02960 200 SL (Sivanto) are summarised in Table B.9.2.4-01. In the tables, it is indicated whether endpoints are based on nominal or actual concentrations. Data indicated in bold are the lowest effect concentrations for that species group.

Table B.9.2.4.01. The acute toxicity of BYI 02960 and BYI 02960 SL 200 to aquatic life. Bold data are the lowest effect concentrations for that specific group.

Metabolites

According to the LoEP from fate and behaviour, the environmental occurring metabolites requiring further assessment by other disciplines (toxicology and ecotoxicology) are:

Surface Water: 6-CNA, DFA, BYI 02960-succinamide, BYI 02960-azabicyclosuccinmaide

Sediment: 6-CNA, DFA

Accepted acute data on the acute toxicity of the relevant metabolites are summarized in Table B.9.2.4-02.

Chironomus riparius	6-CNA (IC-0)	28 d (static; water-spiked)	NOEC	100 ($_{nom}$)

B.9.2.5 Risk assessment

The risk assessment is based on Guidance Document on Aquatic Ecotoxicology, SANCO/3268/2001, rev 4 final, 17 October 2002. Toxicity exposure ratios (TER values) are calculated based on the most sensitive species and worst-case PEC_{SW} values.

The TER-values have been calculated based on the following equations:

TER_A = LC50 or EC50 / maximum PEC_{SW}

TER_{LT} = ErC50 / maximum PEC_{SW}

TER_{LT} = chronic NOEC /maximum PEC_{SW}

The risk is considered acceptable if the TER_A values are ≥ 100, and the TER_{LT} values ≥ 10.

Acute and chronic risk assessment was carried out in tier 1 using the initial PEC_{SW} calculated with FOCUS Surface Water, Step 2, and the lowest available toxicity endpoints for algae, *Daphnia* and other invertebrates, fish, amphibians, and *Lemna*. The resulting TER-values are presented for the different uses of BYI 02960 SL 200 for the a.s. and the metabolites. TERs that do not meet the relevant trigger are indicated in bold.

B.9.2.5.1 Tier 1 risk assessment for fish (and other aquatic vertebrates)

The acute risk assessment for the a.s. is based on the lowest LC50 for fish of >70.5 mg a.s./L; this also covers amphibians since the LC50 for *Xenopus laevis* is higher (>80 mg a.s./L).

Table B.9.2.5.1-01 TER_A calculations for fish based on FOCUS Step 2 for application in hops

Compound	Species	Endpoint [µg/L]	$PEC_{sw,max}$ [µg/L]	TER_A	Trigger
Crop: Hops					
BYI 02960	*P. promelas*	LC_{50} > 70 500	17.36	> 4 061	100
BYI 02960 – succinamide	*O. mykiss*	LC_{50} > 100 000	4.065	> 24 600	
DFA*	*O. mykiss*	LC_{50} > 10 000	1.268 (1.421*)	>7 886 (> 7 037*)	

*) In a worst-case approach, exposure concentrations for DFA are based upon groundwater calculations; however, dilution will occur during transport to surface waters.

Table B.9.2.5.1-02 TER_A calculations for fish based on FOCUS Step 2 for application in lettuce – biennial (covers annual use)

Compound	Species	Endpoint [µg/L]	$PEC_{sw,max}$ [µg/L]	TER_A	Trigger
Crop: Lettuce					
BYI 02960	*P. promelas*	LC_{50} > 70 500	11.88	> 5 934	100
BYI 02960 – succinamide	*O. mykiss*	LC_{50} > 100 000	0.484	> 206 612	
DFA*	*O. mykiss*	LC_{50} > 10 000	1.339 (5.599*)	> 7 468 (> 1 786*)	

*) In a worst-case approach, exposure concentrations for DFA are based upon groundwater calculations; however, dilution will occur during transport to surface waters.

The TERA values meet the required trigger for both uses, indicating an acceptable acute risk to fish for application of the product.

Table B.9.2.5.1-03 TER_{LT} calculations for fish based on FOCUS Step 2 for application in hops

Compound	Species	Endpoint [µg/L]	$PEC_{sw,max}$ [µg/L]	TER_{LT}	Trigger
Crop: Hops					
BYI 02960	*P. promelas*	NOEC 4410	17.36	254	10

Table B.9.2.5.1-04 TER_{LT} calculations for fish based on FOCUS Step 2 for application in lettuce – biennial (covers annual use)

Compound	Species	Endpoint [µg/L]		$PEC_{sw,max}$ [µg/L]	TER_{LT}	Trigger
Crop: Lettuce						
BYI 02960	*P. promelas*	NOEC	4410	11.88	371	10

The TER_{LT} values meet the required trigger for both uses, indicating an acceptable long-term risk to fish for application of the product.

B.9.2.5.2 Tier 1 risk assessment for aquatic invertebrates (including sediment-dwelling organisms)

The acute risk assessment for the a.s. is based on the lowest LC50 for aquatic invertebrates of 0.0617 mg a.s./L, for *Chironomus*. Sediment-spiked tests with *Chironomus* are not available, therefore the risk assessment is performed with PECsw only (so PECsed is not used).

Table B.9.2.5.2-01 TER_A calculations for aquatic invertebrates based on FOCUS Step 2 for application in hops

Compound	Species	Endpoint [µg/L]		$PEC_{sw,max}$ [µg/L]	TER_A	Trigger
Crop: Hops						
BYI 02960	*C. riparius*	EC_{50}	61.7	17.36	**3.53**	100
DFA*	*D. magna*	EC_{50}	> 10 000	1.268 (1.421*)	> 7 886 (> 7 037*)	
6-CNA	*C. tentans*	EC_{50}	> 1 000	0.463	> 2 160	
BYI 02960-succinamide	*C. riparius*	EC_{50}	> 100 000	4.065	> 24 600	
BYI 02960-azabicyclosuccinamide, sodium salt	*C. riparius*	EC_{50}	> 100 000	2.499	>40 016	

*) In a worst-case approach, exposure concentrations for DFA are based upon groundwater calculations; however, dilution will occur during transport to surface waters.

Table B.9.2.5.2-02 TER_A calculations for aquatic invertebrates based on FOCUS Step 2 for application in lettuce – biennial (covers annual use)

Compound	Species	Endpoint [µg/L]		$PEC_{sw,max}$ [µg/L]	TER_A	Trigger
Crop: Lettuce						
BYI 02960	*C. riparius*	EC_{50}	61.7	11.88	**5.20**	100
DFA*	*D. magna*	EC_{50}	**>** 10 000	1.339 (5.599*)	> 7 468 (> 1 786*)	
6-CNA	*C. tentans*	EC_{50}	> 1 000	0.579	> 1 727	
BYI 02960-succinamide	*C. riparius*	EC_{50}	> 100 000	0.484	> 206 612	
BYI 02960-azabicyclosuccinamide, sodium salt	*C. riparius*	EC_{50}	> 100 000	0.297	> 336 700	

*) In a worst-case approach, exposure concentrations for DFA are based upon groundwater calculations; however, dilution will occur during transport to surface waters.

The TERA values meet the required trigger for both uses for the metabolites, indicating an acceptable acute risk to aquatic invertebrates. However, for the acute risk of the a.s., refinement is required.

The long-term risk assessment for the a.s. is based on the lowest NOEC for aquatic invertebrates of ~~0.0102~~ 0.00681 mg a.s./L, for *C.riparius*.

Table B.9.2.5.2-03 TER_{LT} calculations for aquatic invertebrates based on FOCUS Step 2 for application in hops

Compound	Species	Endpoint [µg/L]		$PEC_{sw,max}$ [µg/L]	TER_{LT}	Trigger
Crop: Hops						
BYI 02960	*C. riparius*	NOEC	~~10~~ 6.81	17.36	~~0.58~~ **0.39**	10
BYI 02960 – succinamide	*D. magna*	NOEC	43 300	4.065	10 652	
DFA*	*C. riparius*	NOEC	100 000	1.268 (1.421*)	78 864 (70 373*)	
6-CNA	*C. riparius*	NOEC	100 000	0.463	215 983	

*) In a worst-case approach, exposure concentrations for DFA are based upon groundwater calculations; however, dilution will occur during transport to surface waters.

Table B.9.2.5.2-04 TER_{LT} calculations for aquatic invertebrates based on FOCUS Step 2 for application in lettuce – biennial (covers annual use)

Compound	Species	Endpoint [µg/L]		$PEC_{sw,max}$ [µg/L]	TER_{LT}	Trigger
Crop: Lettuce						
BYI 02960	*C. riparius*	NOEC	~~10~~ 6.81	11.88	~~**0.84**~~ **0.57**	10
BYI 02960 – succinamide	*D. magna*	NOEC	43 300	0.484	89 463	
DFA*	*C. riparius*	NOEC	100 000	1.339 (5.599*)	74 683 (17 860*)	
6-CNA	*C. riparius*	NOEC	100 000	0.579	172 712	

*) In a worst-case approach, exposure concentrations for DFA are based upon groundwater calculations; however, dilution will occur during transport to surface waters.

The TERLT values meet the required trigger for both uses for the metabolites, indicating an acceptable long-term risk to aquatic invertebrates. However, for the long-term risk of the a.s., refinement is required.

B.9.2.5.3 Tier 1 risk assessment for algae

The risk assessment for the a.s. is based on the lowest EC50 for algae of >42.8 mg a.s./L, based on the study with the formulated product.

Table B.9.2.5.3-01 TER_A calculations for algae based on FOCUS Step 2 for application in hops

Compound	Species	Endpoint [µg/L]		$PEC_{sw,max}$ [µg/L]	TER_A	Trigger
Crop: Hops						
BYI 02960	*P. subcapitata*	EC50	>42 800	17.36	>2 465	10
DFA	*P. subcapitata*	EC50	>10 000	1.268	>7 886	10
BYI 02960 – succinamide	*P. subcapitata*	EC50	>10 000	4.065	>2 460	10

BYI 02960	*L. gibba*	EC50	>67 700	17.36	>3 890	10

Table B.9.2.5.4-02 TER_A calculations for lemna based on FOCUS Step 2 for application in lettuce – biennial (covers annual use)

Compound	Species	Endpoint [µg/L]		$PEC_{sw,max}$ [µg/L]	TER_A	Trigger
Crop: Lettuce						
BYI 02960	*L. gibba*	EC50	>67 700	11.88	>5 699	10

The TERA values meet the required trigger for both uses for the a.s., indicating an acceptable risk to algae.

B.9.2.5.5 Refined risk assessment for aquatic invertebrates

Based on the tier 1 risk assessments shown above, acceptable risk is found for the a.s. for fish and other aquatic vertebrates, algae and aquatic macrophytes.

For the relevant metabolites, sufficient toxicity data are available. Acceptable risk is found for all groups.

However, refinement is necessary for the a.s. for the acute and long-term risk to aquatic invertebrates.

The risk is refined on the exposure side, with Step 3 and Step 4 FOCUSsw calculations.

For lettuce, FOCUS Step 4 PECsw values are available both for the annual (once per 12 months) and the biennial (once per 24 months) use. The annual use is proposed at BBCH 41-49, the biennial at BBCH 12-49. Because a higher interception percentage can be taken into account at later crop stages, the PEC values from FOCUS Step 2 are higher for the biennial use. In Step 3 and 4, however, the PEC values are sometimes higher for the annual and sometimes for the biennial use, depending on the scenario. This was not presented clearly in the original DAR, but in this revised version TER values are presented both for the biennial and the annual use.

B.9.2.5.5.1 Refined acute risk assessment for aquatic invertebrates

			2.954	R4 (stream, 2nd)	**20.9**	

For use in hops and both uses in lettuce a safe use is shown at Step 3 for at least one subscenario (TER > 100). Potential mitigation measures are investigated considering Step 4 calculations.

Table B.9.2.5.5-03 Refined TER_A calculations for *C. riparius* based on FOCUS Step 4 for application in hops (90 % drift reduction)

Compound	Species	Endpoint [µg/L]	$PEC_{sw,max}$ [µg/L]	Scenario	TER_A	Trigger
Crop: Hops; 90 % drift reduction (no buffer zone)						
BYI 02960	*C. riparius*	EC_{50} 61.7	0.553	R1, stream	112	100
Crop: Hops; 75 % drift reduction and 10 m buffer zone						
BYI 02960	*C. riparius*	EC_{50} 61.7	0.589	R1, stream	105	100

The above table shows that for hops, acceptable risk can be reached with different combinations of buffer zones and spray drift reduction.

Table B.9.2.5.5-04 Refined TER_A calculations for *C. riparius* based on FOCUS Step 4 for application in lettuce (drift reducing nozzles) – biennial use

Compound	Species	Endpoint [µg/L]	$PEC_{sw,max}$ [µg/L]	Drift reduction [%]	Scenario	TER_A	Trigger
Crop: Lettuce; 50% drift reduction (No buffer)							
BYI 02960	*C. riparius*	EC_{50} 61.7	**0.434**	50	D3 (ditch, 1st)	143	100
			0.446	50	D3 (ditch, 2nd)	139	
			1.033	90	D4 (pond, 1st)	**59.7**	
			0.721	90	D4 (stream, 1st)	**85.6**	
			1.268	90	D6 (ditch, 1st)	**48.7**	
			0.858	90	R1 (stream, 1st)	**71.9**	
			1.186	90	R1 (stream, 2nd)	**52.0**	
			1.586	90	R2 (stream, 1st)	**38.9**	
			0.940	90	R2 (stream, 2nd)	**65.6**	
			2.226	90	R3 (stream, 1st)	**27.7**	
			3.570	90	R3 (stream, 2nd)	**17.3**	
			4.808	90	R4 (stream, 2nd)	**12.8**	

Table B.9.2.5.5-11 shows that for the biennial use in lettuce, most scenario's do not meet the trigger considering drift reducton only. For the annual use in lettuce, PECsw values are not available considering drift reduction only. Therefore, further refinement is necessary for both lettuce uses. FOCUS Step 4 PECsw values are available based on buffer zones (with drift and/or run-off reduction.

Table B.9.2.5.5-05a Refined TER_A calculations for *C. riparius* based on FOCUS Step 4 for application in lettuce (5 m distance) – biennial use

Compound	Species	Endpoint [µg/L]	$PEC_{sw,max}$ [µg/L]	Scenario	TER_A	Trigger
Crop: Lettuce; 5 m drift buffer (no drift reduction)

Conclusion acute risk aquatic invertebrates:

A safe use has been shown for the subscenario R1 (pond) in both hops and lettuce with no risk mitigation.

For hops, acceptable risk can be reached in the one relevant complete scenario with different combinations of buffer zones and spray drift reduction.

For the biennial use in lettuce, by applying mitigation measures an acceptable use can be shown for for ten of the fifteen FOCUS subscenarios considering different mitigation options (up to 20m VFS). ~~scenario D3 with no buffer zone and drift reducing nozzles, and for some of the subscenarios R1 stream, R2 stream and R3 stream considering different buffer zones (vegetated filter strips) and drift reducing nozzles~~. Of the seven complete scenario's, three meet the trigger.

For the annual use in lettuce, by applying mitigation measures an acceptable use can be shown for for eight of the fifteen FOCUS subscenarios considering different mitigation options (up to 20m VFS). Of the seven complete scenario's, two meet the trigger.

B.9.2.5.5.2 Refined long-term risk assessment for aquatic invertebrates

*VFS: vegetated filter strip

Conclusion long-term risk aquatic invertebrates:

Based on the calculations presented above a safe use of the formulation in hops can be shown for all

FOCUS scenarios considering different mitigation options (up to 90% drift reducing nozzles).

Based on the calculations presented above a safe biennial use of the formulation in lettuce can be shown for ten of the ~~thir~~fifteen FOCUS subscenarios considering different mitigation options (up to 20m VFS). Of the seven complete scenario's, three meet the trigger.

A safe annual use of the formulation in lettuce can be shown for nine of the fifteen FOCUS subscenarios considering different mitigation options (up to 20m VFS). Of the seven complete scenario's, three meet the trigger.

Overall conclusion risk aquatic invertebrates:

For hops, acceptable risk can be reached in the one relevant complete scenario with different combinations of buffer zones and spray drift reduction.

For the biennial use in lettuce, an acceptable use can be shown for three of the seven complete FOCUS scenarios considering different mitigation options (up to 20m VFS).

For the annual use in lettuce, an acceptable use can be shown for two of the seven complete FOCUS scenarios considering different mitigation options (up to 20m VFS).

Expert consultation on the risk assessment for aquatic invertebrates (especially insects)

Experts to discuss if a test on mayflies should be considered needed in the aquatic risk assessment. The applicant provided a position paper with input for this discussion. The conclusion of this position paper is included below.

STUDY Q 14 /01 (relevant for KIIA 8.3.2.2

reference	:	Hager, J. (2014)
type of study	:	Position paper on the need for additional data on mayflies (Ephemeroptera)
year of execution	:	not relevant
GLP statement	:	not relevant
guideline	:	not relevant
test substance	:	not relevant

Conclusion of the position paper of the notifier:

"The risk assessment for flupyradifurone is based on tier 1 data including a high margin of safety which covers species potentially more sensitive than standard laboratory species.

There is no well-founded reason for questioning the protectiveness of the tier 1 risk assessment of flupyradifurone:

- The publication by Roessink et al. is an indication that Ephemeroptera are sensitive to imidacloprid. The paper is however **not suitable to question current data requirements and current state of the art of pesticide risk assessment**.
- The publication was presenting results for imidacloprid and not for flupyradifurone
- For the tier 1 risk assessment high assessment factors are given by the current aquatic guidance documents. These assessment factors are chosen in order to provide a margin of safety large enough to cover species that might be more sensitive than the standard laboratory species strictly defined by current regulation. The current risk assessment for flupyradifurone is driven by the acute endpoint for chironomus. Thus the corresponding assessment factor is 100, **including a sufficiently large margin of safety**.
- It is unlikely that Ephemeroptera would be more than 100 times more sensitive to flupyradifurone than chironomids.
- The acute data of the publication by Roessink et al. fit well into the picture of all acute aquatic invertebrate data available for imidacloprid. As the aquatic RAC of flupyradifurone is defined by acute data there is no reason to question its protectiveness based on the publication by Roessink et al.
- The data published by Roessink et al are derived with a compound that is **structurally different from flupyradifurone**.

Hence BCS is of the opinion that there is no concern regarding the current risk assessment for flupyradifurone."

Expert discussion in Pesticide Peer Review meeting 124 of December 2014:

Aquatic invertebrates drive the risk assessment for aquatic organisms. The lowest endpoint that was considered in the higher tier RA was from an acute water-spiked *C. riparius* study that resulted in an EC50 of 61.7 ug/L (the lowest chronic NOEC for *C. riparius* was 10 ug/L).

A comment from the commenting phase highlighted that the concerns about possible effects on mayflies (Ephemeroptera) should be investigated and discussed further because mayflies show higher sensitivity to neonicotinoids compared to Chironomides. It was pointed out that formally all data requirements are fulfilled and no additional data would be needed. Generally, the safety factor should cover such issues (sensitivity between species). On the other hand, recent concerns of imidacloprid for aquatic organisms raised in the open literature should not be omitted as it may underpin some concerns for insecticides.

The applicant provided a position paper for this issue highlighting the official data requirement and standard RA scheme that includes a safety factor, arguing on the difference of the molecule structure of flupyradifurone and imidacloprid and on the uncertainties of testing mayfly.

Discussion:

EFSA clarified that for imidacloprid the data set available at the time of the first peer review already indicated some concerns as regards Ephemeroptera. The endpoint agreed for risk assessment was based on chironomus from a mesocosm study where Ephemeroptera were not enough abundant.

The experts questioned whether potentially more sensitive insects should always be considered for insecticides. Some experts considered that the available data were not sufficient and it is needed to ask for more data because a higher sensitivity for ephemeroptera is expected for this substance. However, not enough data were available to support such a requirement.

The experts discussed in deep the available data on chironomus. Some experts considered that the chironomus endpoint should be expressed in terms of mean measured concentration in the water column since the substance does not partition quickly to sediment. Likely the substance degrades relatively fast in water. The endpoint expressed in this way would be relevant also for other organisms living in the water.

However, the concentration in the sediment was unknown; in the pore water it was relatively low. Therefore, some experts noted that there is not enough information to agree on the mean measured concentration in the whole test system (which could be more appropriate). However, for the water column the information was available therefore the experts agreed to express the chironomus endpoint based on mean measured concentration.

The current TERs with the chironomus standard endpoint expressed in terms of nominal concentrations resulted below the trigger for many scenarios. With the endpoint expressed in terms of mean measured concentrations, likely the majority of scenarios will be below the trigger. Therefore, it is likely that higher tier studies should be performed to further address the risk to aquatic insects. In performing this higher tier assessment, potentially more sensitive insects should also be considered.

B.9.2.5.5.6 Assessment of bioconcentration potential

BYI 02960 and its relevant metabolites have a log Pow of <3, therefore no study on bioaccumulation is required and there is no concern for bioconcentration.

Description

The study presented here was conducted to find out which bird and mammal species visit hop yards, and how much time per day they spent in hop. This information is needed to identify focal species and to determine the time spent in the treated area. Furthermore, the feeding behaviour of these species within hop yards was investigated to determine the proportion of time spent foraging. The hop yards were treated according good agricultural practice (GAP) by local farmers and all their farming activities were recorded. The study aimed to define realistic species of concern and reveal behavioural information for these species.

Methods

The study was conducted in seven hop yards in the 'Hallertau' region between Ingolstadt, Regensburg and Landshut, Germany. This region is the main area of hop cultivation in Europe. Four study plots and their adjacent areas close to nature were chosen to be typical sites for hop cultivation which provided a high diversity of birds and mammals. Three of the four plots were used for the bird inventory, and three plots were used for the mammal inventory. For comparison, three study plots within an intensively cultivated arable area were chosen; results for these plots are not described in the report, but only presented in the summary table, comparing the two types of plots.

The landscape of the first four plots is very diverse, consisting of meadows, set aside hop yards, areas with shrubs and trees, woods, alder forest, ponds and some agricultural used fields.

Soil types were not described in the study.

Birds

Transect counts

Prevalence and abundance of species within six hop yards and surrounding habitats were surveyed by transect counts (three yards surrounded by nature elements, three within the intensively used agricultural area. Counts took place within the yards and in the surrounding, on average 6 times in each of the six fields in the period from 18 June to 30 July 2003. The area's covered by the transect counting are given in Table B.9.3.1-1.

Table B.9.3.1-1 Overview on size of bird census transects and the type of hop yards

No.	Name	Hop-yard [ha]	Surrounding [ha]	Tvpe
1	Giessübel	2.25	2.91	Close-to-nature
2	Buchersried	0.84	1.33	Close-to-nature
4	Axenhofen	0.93	1.49	Close-to-nature
5	Schillwitzried	1.39	2.15	Intensive-use
6	Lindach	1.46	2.13	Intensive-use
7	Unterwanoenbach	1.64	2.56	Intensive-use

The observed area from the observer was assumed to be 30 m. Additionally to species and number of individuals, also behaviour (e.g.foraging, singing/breeding/feeding young, locomotion, resting, others) and exact location (e.g. flying over, resting on wire, in vegetation, on the ground) was recorded to allow later analysis of hop yard use. Species densities were calculated for all birds observed in the corresponding habitat when not grouped as "Flying over, not related to area". To allow comparisons with other data, the size of the area, covered by the observations, was also recorded.

Bird trapping

Birds were trapped by mist-netting within three hop yards in the study site. Two mist nets were attached to each other to ensure a net height of 4.8 m. Three of these arrangements were stringed together to form a net row. On every yard, four rows of nets with a resulting net area of 148.32 m^2 each were placed. In Buchersried (site 2) and Giessübel (site 1), two net rows were located at the hop yard borders and two inside the hop yard. In Axenhofen (site 4), three net rows were placed along the hop yard border and one net row was located inside the hop yard. The nets were checked at least every 30 min. Birds were taken out of the nets and marked individually. The species and age of the bird was identified. Afterwards the bird was released. Trappings were performed on each plot (i.e. plot 1, 2 and 4) for two and a half consecutive days, then the nets were transferred to the next plot and trapping started on the next morning again for 2.5 days. There were five trapping periods on sites Buchersried and Axenhofen and four trapping periods at Giessübel.

Radio telemetry of birds.

In the three hop yards used for bird monitoring, 17 individuals, belonging to 12 species, were tracked after tagging with a radio transmitter. In Giessübel (plot 1), 1 robin, 2 chaffinches and 2 great tits were followed. In Buchersried (plot 2), 1 yellowhammer, 1 goldfinch, 1 blackbird, 1 spotted flycatcher, 1 garden warbler and 1 marsh warbler were tracked. In Axenhofen (plot 4), 2 blackcaps, 1 yellowhammer, 1 mistle thrush, 1 blackbird and 1 chiffchaff were tracked. The radio tagged birds were tracked continuously for one whole day (from dawn to dusk). During tracking each change of habitat (and behaviour if recognisable) was recorded with time and location (on an aerial map fitted with a grid or GPS position). This modified basic data, which is included in the raw data was used for the evaluation. These data allow to calculate the proportion of time the bird spent in a specific habitat type (e.g. the hop yard) and, furthermore, to calculate the size and shape of the total home range (at this day).

Home ranges

To identify the home range, it was calculated from the telemetry data. Every new position of the animals was used for the calculation. Portion of hop yard of the total home range of the individuals.

The calculation of home range sizes and habitat content according to the Minimum Convex polygon (MCP) was performed with the RANGES 6 computer package. The percentage hop yard of the home range for a species was calculated from the mean data of the individuals.

Small mammals

Small mammal trapping

Small mammal live trapping was conducted at three different hop yards in the study site Giessübel (site 1) and in Axenhofen (site 3 and 4). In each yard 45 multi-capture 'Ugglan' live traps were installed in a U-shape. A first line of fifteen traps was set inside to the hop yard parallel to the border (trap distance approximately 10 m, distance to the border approx. 40 m). In a right angle to this first trap line another fifteen traps were arranged with a trap distance of approx. 5 m as a transect line from the surrounding vegetation into the hop yard. The third trap line of 15 traps was set up in a right angle to line two and parallel to line one, and was situated outside the hop yard in the surrounding vegetation with a distance between traps of approximately 10 m (distance to border approx. 25 m). Each trap was covered by a metal roof as shelter against weather and was supplied with crushed oats and hazelnuts as bait and food for trapped animals. The trapping started on 18th of June and was carried out daily with the exception when radio tracking was conducted. Traps were set-up in the evening and checked approximately every six hours, around midnight and in the morning when they were deactivated. Each captured animal was individually marked by a Passive Integrated Transponder (PIT). The PIT was applied in the field by a specific injector. Species, sex, weight, reproductive state, animal ID (the PIT), location (trap), date and time of trapping (checking time) were noted as raw data.

Radio telemetry of mammals

During the study suitable adult individuals trapped in the live traps were supplied with radio collars. Animals were regarded as suitable if the collar weight (approx. 2 g) did not exceed more than 10% of the body weight. Those animals were tracked individually for one 24 h period. While radio tracked, each change of habitat was recorded with time and location (GPS position) of changing. Additionally a GPS position was taken approximately every 15 to 20 minutes. These data allowed to calculate the time in habitat and the potentially foraging time an animal spent in a specific habitat type (e.g. the hop yard) and, furthermore, to calculate the size and shape of the total home range (at this day) and the speed in the different habitats. The potentially foraging time of wood mouse (*Apodemus sylvaticus*) was the active period when foraging was likely. The wood mouse as nocturnal animal is resting during the daytime and is active from dusk till dawn. The potentially foraging time in the hop yard for wood mice was the time an individual spent in the hop yard during the active period.

The speed was calculated from radio tracking data, the time and the distance two consecutive locations of an animal.

Home ranges

See description for birds.

Endpoints of the study

Number and kind of bird and mammal species that can be found in and around hop yards to identify species of concern.
Home range size of birds and small mammals living in hop yards or their vicinity to assess the spatial importance of the cultivation.
Diurnal use pattern of birds and small mammals to assess the proportion of time individuals spend in hop yards.
Any available information about behaviour and diet of birds and mammals in and around hop yards.
Diet of birds could not be determined since distance to the birds was too big to observe the exact feeding.

Results

Birds

Transect counts

In total 50 bird species were found during six census counts in the six fields (see table below). Of these species, 21 were found inside of the hop yards, and all species (except the green woodpecker) were found in the surrounding areas. Most abundant species in the hop yards were chaffinch, wood pigeon, goldfinch, fieldfare, great tit, and greenfinch. Most abundant species in the surrounding areas are starling, fieldfare, chaffinch, great tit, blackbird, wagtail and chiffchaff.

Table B.9.3.1-2. Mean abundance of all species [ind./ha] observed in hop yards and surrounding during six census walks in six hop yards and adjacent areas each, sorted after the abundance inside the hop yards.

Species		Location	
English Name	Scientific Name	Surrounding	Hop Yard
Chaffinch	*Fringilla coelebs*	0,91	0,64

Number of species		50	21
Mean total bird abundance per census [ind./ha]		17,05	6,37

When the close-to-nature hop yards are compared to the hop yards in intensively use areas, it is clear that the close-to-nature hop yards have a higher number of bird species (19 species, mean density was 7.8 individuals/ha in the close-to-nature hop yards compared to 12 species, mean density 4.9 individual/ha in the intensive yards). In the surrounding environment of the close-to-nature hop yards 46 species were observed, mean density 21.4 individuals/ha compared to 22 species, mean density 12.7 in the surrounding of the intensively cultivated area. Most common species inside the close-to-nature hop yards were chaffinch, fieldfare, great tit, wood pigeon, goldfinch and greenfinch with mean abundance of more than 0.5 individuals/ha. Most common species in the hop yards with intensive use environment, were wood pigeon, starling, goldfinch, carrion crow, greenfinch and chaffinch with a mean abundance of more than 0.25 individuals per hectare. Carrion crow and starling were recorded in smaller densities or not all in close-to-nature environment. Chiffchaff, great spotted woodpecker, house martin, jay, and spotted flycatcher were not recorded in hop yards or surrounding of intensively used environment. Results are reported in the following table.

Table B.9.3.1-3 Bird abundance in close-to-nature and intensive-use environment

	Close-to-nature environment		Intensive use environment

Behaviour observed during the transect counts was deemed to be unreliable and not analysed.

Bird trapping

In the three close-to-nature sites, a total of 738 birds of 44 different species were trapped (67 individuals were trapped more than one time, total number of trapping 831, only first traps are taken into account of analyses). Results are based on 14 trapping periods at three sites, values are standardised on mean no. of individuals per net and session, incorporating the varying number of trapping sessions and varying number of mist nets in hop yard and at borders. Results are reported in the table below.

Table B.9.3.1-4 Bird species trap list for hop yard's centre and border (plots 1, 2 and 4, close to nature)

Number of species	16	18	17	31	8	27	25	43		

On average, a number of 4.8 individuals per net and session were caught inside the yards (20.4 % of the total number of birds caught in the nets), and 18.7 individuals were caught in the border areas (79.6%). 19 species were only trapped at the borders. The whitethroat (1 individual) was the only species which was caught exclusively in the centre area of a hop yard. Most common species trapped (sum of border and centre) were blackbird, great tit, chaffinch, robin, chiffchaff, song thrush and blackcap, representing up to 25 % of trapped individuals over all three sites. Overall, chaffinch, blackbird, song thrush, fieldfare, great tit, blackcap and robin were most abundant within the hop yards.

Radio telemetry of birds.

Potential foraging time of focal species

The percentage of time individual birds spent potentially foraging in different habitats is based on 17 radio-tracked individuals, the table below gives an overview on the habitats in which the birds spent their potentially foraging time (referring to known time periods).

Table B.9.3.1.5 Percentage of time individual birds spent potentially foraging in different habitats

Individual		Habitat while potentially foraging

The time periods spent potentially foraging in different habitats by 17 radio-tracked individuals is reported in the following table. The time in which no information on the birds location or behaviour was collected due to loss of signal is shown in the last column. This time period is not included in the time spent potentially foraging.

Table B.9.3.1.-6 Composition of the time spent "potentially foraging" in birds

Mammal trapping

The live trapping revealed that 5 different species had stable populations on the study plots. All species were trapped mainly in the surrounding structure. They preferred the natural habitats instead of the hop yards. Only the wood mouse was caught in significant numbers inside the hop yard (37.5 %) and was the most abundant species inside the hop yard.

Radio telemetry of mammals.

Time spent in different habitats of individuals that were radiotracked is reported in the following table.

Table B.9.3.1-8 Individual time in habitat of small mammals

species	animal ID	site	portion of time in habitat [%]					
			hop yard	wood land	grass land	field path	hedge row	game stripe[A]
Apodemus flavicollis	7200262624	1	0.4	98.2	-	1.4	-	-

	7200272637	4	-	97.3	2.7	-	-	-

[A] Game strip on study site 3 consisted of maize.
[B] This individual was tracked in a thin arm of a big maize field on study site 1.
[C] Due to methodological problems the individual was tagged in the morning and radio tracked directly afterwards. So the place where it spent the day might not be their nest. The wood mouse as nocturnal animal just crashed into the next possibility.
[D] The individual was tagged in the morning and directly left the hop yard and did not return. So the individual did not use the hop yard during the potentially foraging time.

The mean data per species showed that *Apodemus flavicollus, Clethrionomys glareolus* and *Microtus agrestis* spent 97% or more of the time in the wood lands. *Microtus arvalis* spent approximately 40% of its time in the game stripe, 40% in the wood lands and 20% in the hop yard and *Apodemus sylvaticus* spent approximately 60% of its time in the wood lands, just over 20% in the grassland and 13% of its time in the hop yard.

Of the time the wood mice spent in total foraging, the mean potentially foraging time in hop yard is 24.2%.

Home ranges

Because of the small number of tracked individuals the results of all individuals of one species in one area were pooled and with these data the percentage of test hop yard of the total home range on the study sites was calculated. Summarising the results of the three plots for each species: 37.6 % of the wood mice home range was situated in the test hop yards. For the yellow-necked it was 18.7 %, for the common voles 40.0 %, for the bank vole 16.3% and for the field vole 31.9 %, even if the last two species never enter the hop yards at all. This discrepancy is due to the method of the minimum convex polygon calculation.

Remarks

To identify the bird species of concern for hop cultivation, three study plots within an intensively cultivated area (plots 5, 6 and 7) were chosen for comparison with four plots close to nature areas (plots 1-4). This was done to investigate the influence of the structure of surrounding habitats on bird activity inside the hop yards. There is no description of the habitat of the plots that were intensively cultivated (sites 5, 6 and 7).

Bird trapping only took place on study plots 1, 2 and 4 at hop yards in a close-to-nature environment. Mammals were only monitored in plots 1-4.

Bird census took place in six plots. The bird census walks on the six plots showed that species diversity and abundance was considerably higher in the close-to-nature environment than in the monitored hop yards in intensive use environment.

The quality of the study is good. The techniques used in this study (transect and scan counts, trapping, radio tracking) are sound techniques to provide information on the occurrence and abundance of bird and mammals and whether these species do forage in certain crop types or eat certain crops or parts of the crop.

The MCP method was used in this study to calculate home ranges and is a non-probabilistic estimation that does not assess the probability of occurrence of the animal. This method was used by the author to calculate the home range for the mammals. For the birds only the MPC for individual species were provided but no overall assessment was presented. The MCP method was used as a standard method to make their data comparable to published data. Different core centres can be examined in this method. For this evaluation a 100% core centre was assumed so that all outliers were also included. By this means, the real size of the home range is overestimated. Using this method, often artefacts occur and results may imply that the home range includes a specific habitat, even if the individual never entered, but only surrounded it. Therefore the results of the MCP method cannot be used for risk assessment.

The hop yards are clearly not preferred by most bird species. The results of the census counts and the trapping approach showed that the chaffinch (*Fringilla coelebs*) was the most abundant species within the hop yards. The two tracked chaffinches spent on average 50.2 % of their potentially foraging time in the hop yard thus also for this aspect (percentage of time spent), this species reached the highest value.

The live trapping of mammals showed that they preferred the natural habitats instead of the hop yard. The wood mouse was the most abundant species inside the hop yard and was the only species tracked regularly inside the hop yard. The average potentially foraging time in the hop yard was 24 % for the individuals tracked inside the hop yard.

It should be noted that the results from this study (for both mammals and birds) are based on hop yards close to nature areas. It is not clear if the same focal species can be used for hop yards in an intensively cultivated area, if present at all. For intensively cultivated areas the starling, wood pigeon, goldfinch and the greenfinch (see Table 10.3.1-3) are more abundant than the chaffinch. Mammal trapping was only conducted in the hop yards close to nature, therefore it is not possible to compare species abundance between plots in intensively cultivated area and plots close to nature areas.

Furthermore, few individuals were radio-tracked per species (at most two per species for birds, two to eight per species for mammals).
Results of this study can only be used taking these remarks into account.

B.9.3.2 Residue data (IIIA 10.3.3)

STUDY IIIA, 10.3.3/02

Characteristics

reference	:	Uceda L. (2012)	Locations/crops	:	2 X Europe-N (1x wheat, 1 X barley) and 2 X Europe-S (1x wheat, 1 X barley)
type of study	:	Field residue trials (residue decline)	Growth stage at treatment	:	BBCH 25-29
year of execution	:	2010-2011	Treatment rate	:	1 x 125 g a.s./ha (spray)
GLP statement	:	Yes	Residues	:	BYI 02960, difluoroacetic acid and BYI 02960-difluoroethylaminofuranone, all calculated as BYI 02960; 6-chloronicotinic acid.
guideline	:	EU 7029/VI/95 rev.5 (1997)	acceptability	:	Acceptable for BYI 02960, difluoroacetic acid and BYI 02960-difluoroethylaminofuranone.
test substance	:	BYI 02960 SL 200 g/L (200 g/L SL formulation), batch 2010-007173	Endpoint	:	See residue values in Tables below.
a.s. content	:	198.6 g/L BYI 02960			

Methods

The magnitude of the residues of BYI 02960 in/on barley and wheat (sample material green material) after one spray application with BYI 02960 SL 200 g/L was determined in residue decline trials on two locations in Northern Europe and two in Southern Europe up to 21 days after application.

Information on the trial locations is provided in Table B.9.3-01 below. Each trial included one treated and one untreated plot. Treatment dates for trials 01, 02, 03 and 04 were 11 April 2011, 29 March 2011, 07 March 2011 and 18 March 2011, respectively. The crop of each plot was treated once with BYI 02960 SL 200 g/L at a rate of 125 g a.s./ha in 300 L water/ha. At the time of treatment, the BBCH growth stage of the crop was 29, 25, 29 and 29 for trial 01, 02, 03 and 04, respectively. Samples of green material were collected for residue analysis at 0, 1, 3, 4-5, 7, 10, 14-15 and 21 DAT (Day After Treatment). Residues of BYI 02960, difluoroacetic acid, BYI 02960-difluoroethylaminofuranone and 6-chloronicotinic acid were determined by method 01212 (extraction with acetonitrile/water/formic acid (80/20/0.22 v/v/v), addition of internal standard, purification by clean up with cationic resin, HPLC-MS/MS). Residues of BYI 02960, difluoroacetic acid and BYI 02960-difluoroethylaminofuranone were calculated as BYI 02960 (in agreement with the plant residue definition for risk assessment). The LOQ was 0.01 mg/kg for BYI 02960 and BYI 02960-difluoroethylaminofuranone calculated as BYI 02960, 0.02 mg/kg for difluoroacetic acid calculated as BYI 02960, and 0.005 mg/kg for 6-chloronicotinic acid calculated as 6-chloronicotinic acid (equivalent to 0.01 mg/kg as BYI 02960). Concurrent validation was provided (calibration, recovery and repeatability at LOQ and higher levels, chromatograms) and considered to be adequate to support the validity of the residue values. The storage period of deep-

frozen samples intended for the analysis of BYI 02960 and its metabolites ranged between 214 and 270 days. The List of Endpoints states that during a storage period of 12 months under deep-freezer conditions, the components of the relevant residues of BYI 02960 (including parent compound, BYI 02960-difluoroethyl-aminofuranone, and DFA) were stable in orange fruit (high acid content), spinach leaves and tomato fruit (high water content), wheat grain (high starch content), bean seed (high protein content), coffee bean and soybean seed (high oil content), and sugar cane. Wheat and barley green material is a watery matrix and thus considered to be covered by storage stability data for spinach leaves and tomato fruit. Therefore the residue values for parent compound, BYI 02960-difluoroethyl-aminofuranone, and DFA are valid with respect to storage stability. However, the storage stability of 6-chloronicotinic acid under frozen conditions in watery matrix for a period of 270 days (9 months) should be addressed in order for the results for this compound to be valid.

[1] For the calculation of the total residue of BYI 02960 calc. as it appears in the result table above, unrounded values were used. Therefore, minor deviations may occur between the total residue value shown above and when the values given for the individual analytes in the table are summed. In cases in which the residue levels for all analytes are below the respective LOQs in a given sample, the total residue of BYI 02960 calc. is reported as < 0.04 mg/kg (the sum of the individual LOQs). If a residue value is at or above the individual LOQ level for at least one analyte in a sample, all other values below the respective LOQs in that sample are set at the LOQ before the total residue is calculated (0.01 + < 0.02 + < 0.01 = 0.04 mg/kg)

Conclusion

Residues of BYI 02960, difluoroacetic acid, BYI 02960-difluoroethylaminofuranone and 6-chloronicotinic acid were determined up to 21 days after treatment, after one treatment of wheat or barley with BYI 02960 SL 200 g/L at BBCH 25-29 in March-April 2011 in Europe-N (2 trials) or Europe-S (2 trials) at 125 g a.s./ha.

Guidelines & Limitations

The study is acceptable. The storage stability of 6-chloronicotinic acid under frozen conditions in watery matrix for a period of 270 days (9 months) should be addressed in order for the results for this

compound to be valid; however, since 6-CNA is not considered relevant for bird and mammal risk assessment, this information is not needed for this DAR.

IIIA 10.3.3/03

Characteristics

reference	:	Scherr F. & Ellerich C. (2013)	study type	:	modelling study (estimation of DT50)
year of execution	:	2013	Crop	:	lettuce
GLP statement	:	not applicable	Residues	:	Flupyradifurone only and total residues of flupyradifurone
guideline	:	Focus Kinetics v 2.0 (2006)	Endpoints	:	See Tables 7-10
test substance	:	Flupyradifurone (BYI 02960)	acceptability	:	Acceptable

NB For an earlier version of the DAR, another kinetic evaluation of the lettuce trials was submitted (Sur R. and Ellerich, 2012). After discussions between the RMS and the notifier, a revised version of the modelling was submitted. This revised version is considered to be the most relevant for risk assessment and is the only one presented here.
Please note that the summaries/evaluations of the residue trials in lettuce can be found in Vol.3 B.7.

Study Design and Methods

Kinetic modelling analysis of data from field residue trials in lettuce performed in Northern and Southern Europe with flupyradifurone (BYI 02960) was performed in order to derive DT50 values for flupyradifurone only and total residues of flupyradifurone (sum of flupyradifurone, difluoroacetic acid and BYI 02960-difluoroethylaminofuranone, expressed as flupyradifurone). The residue trials originated from the following reports: Noss, G., Bauer, J. (2012), Determination of the residues of BYI 02960 in/on lettuce after spraying of BYI 02960 SL 200 in the field in the Netherlands, Belgium, France (North) and Germany, Edition Number: M-424742-01-1,Study Report Number: 10-2223; Schoening, R., Bauer, J. (2012), Determination of the residues of BYI 02960 in/on lettuce, head after spray application of BYI 02960 SL 200 in the field in France (South), Spain and Italy - Amendment no. 0001 to report no. 10-2213; Uceda, L. (2012a), Determination of the residues of BYI 02960 in/on lettuce after spray application of BYI 02960 SL 200 in the field in Spain, Italy, Southern France and Portugal, Edition Number: M-425784-01-1, Study Report Number: 11-2071; Uceda, L. (2012b), Amendment No. 1 - Determination of the residues of BYI 02960 in/on lettuce after spray application of BYI 02960 SL 200 in the field in Germany, northern France and Belgium, Number: M-425941-02-1, Study Report Number: 11-2082. In all trials lettuce was treated twice with a 9-11 day interval at rate 125 g a.s./ha. In all trials residues of flupyradifurone were determined after the second treatment, but in a few trials residues of flupyradifurone were also determined after the first application. DT50 values were estimated for each decline interval. The data used for modelling, which comprised for each set only 5 data points, are summarised in Table 1 and 2. These data were checked by the RMS and corresponded with the original study data, except in one case (trial R17), and for this reason this data set was recalculated by the RMS (see “Evaluation by RMS”).

Data handling was in agreement with the guidance provided by FOCUS Kinetics (2006). In cases where the original residue data contained the value <LOQ, the next non-detect was replaced by 0.5xLOQ. The degradation rate of was evaluated using the software package KinGUI (version 2.2011). The kinetics were evaluated in a stepwise approach, first using SFO, and if the SFO fit was not acceptable, in addition by the bi-phasic model DFOP. The goodness of fit of the kinetic models was assessed both statistically (χ2-error for fits and t-test parameter) and visually (plots of actual versus modelled residues, residuals plots), in accordance with the guidance provided by FOCUS (2006).

Results

The reported results are summarised in Table B.9.3.2-06 and -07 (flupyradifurone only) and Table -08 and -09 (total residues of flupyradifurone). All relevant raw data were provided in the report and included plots of fitted versus measured values and residuals plots. All fits and all plots were subjected to review by the RMS and the assessment by the RMS is provided following the Tables. Data sets for which additional estimations were performed by the RMS are shaded in Tables B.9.3.2-06-09 below.

Note: values for k_{fast} and k_{slow} were added by the RMS.

Evaluation by RMS

The reported assessment is acceptable, with the following annotations/exceptions.

- In a number of cases, the k_{slow} and/or k_{fast} of DFOP fitting was not statistically significantly different from zero at the 10% level (p was >0.1). However, the data sets consisted of only 5 data points and for such a small data set statistical significance of DFOP parameters is not easily achieved. In all cases however the visual assessment of the DFOP fit was excellent, and the X2 error values were low, and the DFOP endpoints are considered acceptable, unless noted differently below.
- Trial R17, after 1st application, flupyradifurone alone and total residues of flupyradifurone: The sampling times used in the modelling report were 0, 2, 5 and 8 days, but this should be 0, 3, 6 and 8 days. Modelling was performed by the RMS using KINGUI based on the correct data. For both data sets the SFO fit was visually and statistically acceptable.
- Trial R07, flupyradifurone alone and total residues of flupyradifurone: According to the modelling report SFO fit was acceptable, however visual assessment indicates that the decline is biphasic (see Figure B.9.3.2-04). DFOP modelling was performed by the RMS and gave a fit which was visually better than SFO (see Figure 2) and had a lower X2 error value. The t-test for the k_{slow} and k_{fast} of DFOP fitting was not statistically significantly different from zero at the 10% level (p was >0.1), however this is considered to be acceptable (see first bullet).
- Trial R04, total residues of flupyradifurone: According to the modelling report SFO fit was acceptable, however visual assessment indicates that the decline is biphasic (see Figure 3). DFOP modelling was performed by the RMS and gave a fit which was visually better than SFO (see Figure 3) and had a lower X2 error value. The t-test for the k_{slow} and k_{fast} of DFOP fitting was not statistically significantly different from zero at the 10% level (p was >0.1), however this is considered to be acceptable (see first bullet).
- Trial R17, 2nd application, total residues of flupyradifurone: According to the modelling report SFO fit was acceptable, however visual assessment indicates that the decline is biphasic (see Figure 4). DFOP modelling was performed by the RMS and gave a fit which was visually better than SFO (see Figure 4) and had a lower X2 error value. The t-test for the k_{fast} of DFOP fitting was not statistically significantly different from zero at the 10% level (p was >0.1), however this is considered to be acceptable (see first bullet).
- Trial R05, total residues of flupyradifurone: The modelling report performed the DFOP fitting using the residue values of flupyradifurone instead of those of total residues of flupyradifurone. DFOP modelling was performed by the RMS using the correct values and gave an acceptable DFOP fit (see Figure 5). The t-test for the k_{slow} and k_{fast} of DFOP fitting was not statistically significantly

different from zero at the 10% level (p was >0.1), however this is considered to be acceptable (see first bullet).

A summary of the acceptable study endpoints, consisting of the acceptable endpoints from the modelling report and the endpoints recalculated by the RMS, is provided in Table B.9.3.2-10-13.

Note: values for k_{fast} and k_{slow} were added by the RMS.

Conclusions

The acceptable endpoints (SFO and DFOP rate constants and DFOP g values) are summarised in Tables B.9.3.2-10 to -13 above.

Guidelines & Limitations

Comments were incorporated in the above summary. The conclusion as stated above is acceptable. Comment on how to use these data for risk assessment: Since the best fit was obtained from different models, (SFO for some, DFOP for others), it is not possible to derive an overall average first order DT50 for residue decline on lettuce. For the risk assessment, an f_{TWA} for each individual SFO or DFOP (set of) endpoint(s) should be calculated followed by averaging of all f_{TWA} values obtained this way.

Study design

The aim of this modelling study was to derive first order half-lives (DT50 values) of BYI 02960 and total residue of BYI 02960 in wheat and barley green material based on residue data from outdoor field trials at 4 locations (2 trials R01 and R02 in Europe-N, 2 trials R03 and R04 in Europe-S), performed using 1 treatment at 125 g a.s./ha. The residue trials concerned were summarised in section B.9.3 of the DAR (study IIIA 10.3.3/02) and the reader is referred to the summary of that study for the residue data that were used for estimating DT50 values.

In a first approach, the single first-order (SFO) model was used for the estimations. Single first-order kinetics (SFO) is a simple exponential equation with only two parameters

$M = M_0 e^{-kt}$ (1)

where

M = Total amount of chemical present at time t

M_0 = Total amount of chemical present at time t=0

k = Rate constant (=ln2/DT50).

Where no acceptable SFO fit was obtained, the Double-First-Order in Parallel (DFOP) model was fitted to the data. This model assumes that there are two SFO compartments with specific relative size g and 1-g, and degradation rate constants k1 and k2. The DFOP model contains three kinetic

parameters and is suitable to describe bi-phasic degradation behaviour. The integrated model equation can be written as follows:

$M = M_0 (g\, e^{-k1t} + (1-g)\, e^{-k2t})$

where

M = Total amount of chemical present at time t

M_0 = Total amount of chemical applied at time t=0

g = Fraction of M0 applied to compartment 1

k1 = Rate constant in compartment 1 (=ln2/DT50fast)

k2 = Rate constant in compartment 2 (=ln2/DT50slow).

The best fitting values of the kinetic parameters in the equation discussed above were determined by a numerical optimization process. Using non-linear least square fitting algorithms the parameter values leading to the smallest deviations between observed and calculated residues were determined. Apart from the kinetic rates *k* also the initial amount was fitted, as well as the parameter g for DFOP fitting. Dissipation half-lives (DT50) were calculated from the dissipation rates *k*, as DT50 = ln(2) / k.

Evaluation was based first and foremost on visual inspection of the fitted graph and the residuals. A statistical measure of the quality of a fit was given by the χ2–test (according to FOCUS Kinetics (2006), the χ2 error ε should preferably be <15%). A t-test was employed to identify the probability that a parameter is not significantly different from zero.

The model fit as well as the statistical evaluation of the results was carried out with the in-house developed software KinGUII.

Results

The results are summarized in the Tables below, and the reported fits are displayed in Figure B.9.3-04 (BYI 02960) and Fig B.9.3-05 (BYI 02960 total residue).

Comments by RMS

(1) In 18 trials performed in lettuce (see previous study), there was no remarkable difference between the results from trials in Europe-N and Europe-S. The data set for cereals was too small (n=2 for Europe-N, n=2 for Europe-S) to make a robust comparison, but the available data do not suggest a remarkable difference. Hence for risk assessment the results from the trials in Europe-N and Europe-S may be combined.

(2) Since the best fit was obtained from different models, (SFO in 3 trials, DFOP in 1 trial), it is not possible to derive an overall average first order DT50 for residue decline on cereals. The approach followed in the applicant's risk assessment was calculating f_{TWA} for each individual SFO or DFOP (set of) endpoint(s) followed by averaging of all f_{TWA} values obtained this way.

Conclusions

DT50 for decline of residues of BYI 02960 and total residue of BYI 02960 in cereals based on residue data from 4 outdoor field trials (2 in Europe-N, 2 in Europe-S) were determined (see Table B.9.3-07 to

Table B.9.3-10). The best fit model was SFO in 3 trials and DFOP in 1 trial.

Guidelines & Limitations

Comments were incorporated in the above summary. The conclusion as stated above is acceptable.

B.9.3.3 Summary of toxicity endpoints for mammals

Acute and chronic toxicity data

The summary of the toxicity profile of the active substance BYI 02960 to mammals is provided in Table B.9.3.3-1. Details of the studies concerned are provided in B.6 of this DAR.

Table B.9.3.3-1 Toxicity of BYI 02960 to mammals

Test species	Test design	Ecotoxicological endpoint			Reference
Acute risk assessment endpoint:					
Rat	acute oral, toxic class method	$LD_{50, cut-off}$ [1)] (4/6 dead at 2000, 0/6 at 300)	2000	mg a.i./kg bw	[redacted] (2009) B.6.2.1 Study 1
Rat	acute oral neurotoxicity study	LD_{50} (2/24 dead at 800, 0/24 at 200 and below)	> 800	mg a.i./kg bw	[redacted] (2009) B.6.7.1 Study 1
Combined LD_{50} calculation (TOXCALC, probit): 1607 mg/kg bw					
Reproductive risk assessment endpoint:					
Rat reproduction	Dietary exposure over 2 generations	$NOAEL_{maternal}$ $NOAEL_{repro}$ $NOAEL_{offspring}$	6.4~~7.8~~ [1)] (100 ppm) 34 ~~39.2~~ [2)] (500 ppm) 6.4~~7.8~~ [1)] (100 ppm)	mg a.i./kg bw/d mg a.i./kg bw/d mg a.i./kg bw/d	[redacted] (2011) B.6.6.1 Study 2
Rat developmental toxicity	Gavage over GD 6-20 (gestation days)	$NOAEL_{maternal}$ $NOAEL_{offspring}$	50~~15~~ 50	mg a.i./kg bw/d mg a.i./kg bw/d	[redacted] (2010)
Rabbit developmental toxicity	Gavage over GD 6-28 (gestation days)	$NOAEL_{maternal}$ $NO(A)EL_{offspring}$	15 40	mg a.i./kg bw/d mg a.i./kg bw/d	[redacted] (2012)
Reproductive risk assessment endpoint proposal of notifier		**Tier 1:**	6.4~~7.8~~ **mg/kg bw/d**		
		Tier 2 (refined):	34 ~~39.2~~ **mg/kg bw/d**		

1) Mean achieved dose of P & F1 females at 100 ppm (Table 5.6-14 of KIIA 5.6.1/02, Milius, 2011) In B.6, the NOAEL is based on the lowest intake by either males or females during a particular study phase, in this case intake by males F1-gen during premating, see Table 6.6.1-8 of Vol3 B.6.

2) Mean achieved dose of P & F1 females at 500 ppm (Table 5.6-14 of KIIA 5.6.1/02, Milius, 2011) In B.6, the NOAEL is based on the lowest intake by either males or females during a particular study phase, in this case intake by males F1-gen during premating, see Table 6.6.1-8 of Vol.3 B.6.

There are no indications that the formulated product enhances the toxicity of the a.s., see the Table

below.

Table B.9.3.3-2 Mammalian toxicity data of the formulated product BYI 02960 SL 200

Test species	Test design	Ecotoxicological endpoint	Reference
Rat	acute, oral	LD50 >2000 mg/kg bw [1)]	[redacted] (2010) B.6.12.1 Study 1

1) 0 out of 6 animals died. According to OECD Guideline 423, the LD50 cut-off of BYI 02960 SL 200 is >5000 mg/kg body weight (equivalent to Category 5 (unclassified) of the GHS).

The proposed **acute endpoint of 1607 mg/kg bw** (derived by combining the mortality data from the two acute studies with oral exposure with the a.s.) is accepted.

As long-term endpoint, the notifier proposes a maternal and offspring NOAEL of 100 ppm (7.8 mg/kg bw/d) for tier 1 risk assessment. ~~As a worst-case approach is acceptable but RMS notes that in the mammalian toxicology section of the DAR the endpoints are set at a higher dose level. Also for the developmental studies the endpoints in B.6 of the DAR are higher. See Table B.9.3.3-2.~~

~~Table B.9.3.3-2 Endpoints from 2-generation study in rats and developmental studies in according to B.6.6.1~~

~~Study type~~	~~Reproductive endpoint determined in B.6 :~~	~~Dose (ppm):~~	~~Dose (mg/kg bw/d):~~	~~Based on intake during study phase:~~
~~Rat reproduction~~	~~Relevant parental NOAEL~~	~~500 ppm~~	~~32 mg/kg bw/day~~	~~premating, P-gen, males~~
~~Rat reproduction~~	~~Relevant reproductive NOAEL~~	~~500 ppm~~	~~34 mg/kg bw/day~~	~~gestation, P-gen, females~~
~~Rat reproduction~~	~~Relevant offspring NOAEL~~	~~500 ppm~~	~~34 mg/kg bw/day~~	~~gestation, P-gen, females~~
~~Rat developmental~~	~~Relevant maternal NOAEL~~		~~50 mg/kg bw/day~~	
~~Rat developmental~~	~~Relevant offspring NOAEL~~		~~50 mg/kg bw/day~~	
~~Rabbit developmental~~	~~Relevant reproductive NOAEL~~		~~40 mg/kg bw/day~~	
~~Rabbit developmental~~	~~Relevant offspring NOAEL~~		~~40 mg/kg bw/day~~	

~~Based on the above, the endpoint proposed by the notifier for the first tier is considered to be very conservative.~~ For a tier 2 assessment, the notifier reconsidered this endpoint. Their statement is presented below, with minor modifications by RMS, regarding references to Tables and dossier sections. RMS also incorporated the changes made following Pesticide Peer Review meeting 122 of mammalian toxicology.

According to the refinement options provided in the EFSA GD (Section 4.4, Module 4: Reproductive risk assessment for mammals, step 9), the Tier 1 endpoint can be refined after re-examination of the reproductive studies for endpoints relevant for reproductive performance. Effects on other endpoints can be disregarded. In this context the EFSA GD specifies a number of potentially relevant endpoints to be evaluated, including body weight, behavior and reproductive performance of adults, and observations on offspring (number, weight, development). A corresponding evaluation for BYI 02960 is presented in the table below, based on the toxicological studies summarized in more detail B.6 of this dossier. If such refinement of the Tier 1 endpoint is considered, the EFSA GD recommends that additional mammalian toxicity studies should also be examined in order to check whether they contain lower NOAELs for relevant endpoints.

Approach taken in this evaluation:

In order to ensure a high level of protection, all repeated dose oral toxicity studies conducted with BYI 02960 in rodents (rat, mouse), rabbits or dogs were evaluated for potentially relevant endpoints. This evaluation included also neurotoxicity studies, in order to account for non-lethal behavioral effects that could become relevant under field conditions.

Since the protection goal of the reproductive risk assessment is the sustainability of potentially exposed wild mammal populations, these studies were evaluated with regard to population level relevant endpoints, i.e. survival, growth, development, behavior and reproductive performance. Other endpoints (e.g. organ weights, physiology, blood chemistry etc.) were not included in the evaluation. Furthermore, neither very high doses (more than 3-fold above the proposed refined endpoint), nor chronic studies of extreme exposure duration (≥ 1 year) were included in the tables.

Since effects on females are typically more relevant for small mammal populations than effects on males, the results of this evaluation are presented in Table B.9.3.3-4 in the order of increasing achieved doses for females over all evaluated studies. In order to facilitate the comparison of effects at the different dose levels of each study, the letter code in the first column indicates the study ID (letters A-N, as presented in the following overview table), with the respective dosing group indicated by numbers 1-3 (low, mid and high dose level).

Results of this evaluation:

Most prominent in the evaluation of all these repeated oral dosing studies with BYI 02960 (see Table B.9.3.3-4) were observations of moderate body weight effects. Severity of effects was seen to increase with dose and exposure time.

Within reasonable timeframes of environmental exposures (weeks to months), effects of ecological relevance on wild mammal population did not occur at dose levels of at least 30-50 mg/kg bw/d.

In contrast, pronounced reproductive effects of clear ecological relevance did occur at dose levels significantly exceeding 100 mg/kg bw/d (e.g., 14.8% litter size reduction and reduced body weight of > 10% at 120-150 mg/kg bw/d (1800 ppm) in the rat 2-generation study), and only after prolonged exposure in a second generation (F1 females or F2 offspring).

Moderate effects of bodyweight can usually be considered less relevant in wild mammal risk assessments. Moreover, the results of the 90-d rat study with BYI 02960 showed that bodyweight effects approaching 10% (e.g., 8.9% in males and 9.5% in females at 500 ppm) were reversible after cessation of treatment (recovery phase). Potential exposure of wild mammals to BYI 02960 is transient and short-lived (single application, DT50 on foliage ≤ 5 days). Therefore an effect magnitude of ≤ 10% on bodyweight can be considered ecologically acceptable. Body weight effects exceeding this magnitude were not observed at dose levels below 140 mg/kg bw/d (P females: 15.9%), even after prolonged exposure.

Reproductive effects like reduction of litter size were only moderately pronounced and were only observed after long-term exposure in F1 parents and F2 litter (note: not observed in the 1-generation rat reproduction study nor in the first generation of the 2-generation study), indicating reduced risk for reproductive effects under environmentally relevant conditions (low application rate, single application, DT50 on foliage < 5 days).

Overall, this evaluation suggests that a dose level of up to 39.2 mg as/kg bw/d (achieved dose of

females at 500 ppm in the 2-gen rat reproduction study) can be proposed as relevant and sufficiently conservative risk assessment endpoint for wild mammal populations:

- no ecologically relevant effects in the parental generation or the F1 litter
- only slight reductions of bodyweight (< 10%) in F1 parents and F2 litter
- body weight reduction by BYI 02960 of ca. 10% was reversible after cessation of dosing.

Severe effects only occurred at dose levels which were 3-4 times higher than 39.2 mg/kg bw/d.

Therefore the refined wild mammal reproductive risk assessment endpoint proposed in this dossier is 39.2 mg as/kg bw/d, the achieved dose of females at 500 ppm in the 2-gen rat reproduction study.

Table B.9.3.3-4 Potentially relevant wild mammal reproductive risk assessment effects of BYI 02960 in repeated oral dosing studies

F: females; M: males; ↑: increase (higher than control); ↓: reduction (lower than control);
P: parental generation M+F; F1: offspring produced by P M+F, F2: offspring produced by F1 M+F
#: number; bw: body weight; FC: food consumption
n.e.: not evaluated (specific study type without reproductive endpoints); empty fields: no effect observed. Blue shading indicates the NOAELs as determined by RMS in B.6 of the original DAR. Green shading indicates the NOAELs as determined in the updated version of B.6 of December 2014 following Pesticide Peer Review meeting 122.

ID	Species & study type	Dose ppm	mg/kg bw/d* males	mg/kg bw/d* females	Potentially relevant findings in adults	Potentially relevant findings on reproduction and offspring

*NOAEL set by RMS in original DAR but not accepted in peer review.

~~RMS agrees with the notifier that the ecologically relevant endpoint for wild mammals is the mid-dose of the two-generation study in rats (500 ppm). Based on the mammalian toxicology assessment (see table B.9.3.3-2) this corresponds to **34 mg/kg bw/d,** based on intake by females of the P-generation during the gestation period. This is considered to be the relevant endpoint for the ecotoxicological risk assessment.~~

Expert consultation during Pesticide Peer Review meeting 124, ecotoxicology, December 2014:

The 1-year dog study concluded an endpoint of 7.8 mg/kg bw (mammalian toxicity section, original DAR) and it was questioned whether this should be taken into account.

Furthermore, the endpoint from the 2-generation rat study has changed to 'parental' and 'offspring' NOAEL of 6.4 mg/kg bw per day (100 ppm) and 'reproductive' NOAEL of 32 mg/kg bw per day (500 ppm). The 'parental' NOAEL of 6.4 mg/kg bw per day is based on significant decrease in body weight (<10% observed in the mid-dose of the F_1 females) and a non-significant decrease in body weight gain found in the parental animals (21% in females) and the F_1 animals (16% in females). The 'offspring' NOAEL of 6.4 mg/kg bw per day is based on reduced body weight/body weight gain in the F_2 pups. These were agreed by the meeting of experts for mammalian toxicology (PESTICIDES PEER REVIEW MEETING 122).

Discussion:

The 1y-dog study was considered as not relevant for ecotox for reproductive risk assessment. Some observed effects (degeneration of skeleton muscle and other muscle degeneration) from this study might be considered as relevant but not for the reproduction. It was noted that in general such type of study is not considered robust by tox experts (few test individuals).

The discussion was focussed on the 2-generation rat study. Three endpoints are available from this study, NOAEL of 500 ppm for reproduction and 100 ppm for offspring and parental toxicity. A dose response relationship was noted for the pup body weight decrease. At 500 ppm the decrease was statistically significant but < 10%. It was questioned if this should be considered as biologically relevant. At 1800 ppm (the next higher dose) the decrease was >10%. Some experts considered that the statistical significance in this case should not be disregarded considering also the dose response relationship and preferred the lowest NOAEL of 100 ppm.

Overall, the majority of the experts considered that a NOAEL of 100 ppm should be used for risk assessment (**6.4 mg a.s./kg bw/d**).

Risk to mammals of metabolites of BYI 02960

The notifier provided the following information: " The toxicological properties of two metabolites of BYI 02960 were investigated in a series of studies and evaluated in more detail in section KIIA 5.8 of this submission. Toxicological studies performed on two other metabolites which are also common metabolites to other agrochemicals are also reported in this section. Only a brief summary of the results of these studies is presented in this section. Overall, the results indicate that none of the metabolites is more toxic to mammals than the parent, so that the risk assessment for wild mammals can be based on the toxicity and exposure ratios calculated for BYI 02960 a.i.

The metabolite difluoroacetic acid (DFA) is a major soil, water and plant metabolite and is found in the rat ADME study at an amount of around 6%. It is considered a non-relevant metabolite in terms of the EU Guidance document Sanco/221/2000-rev.10 (25 February, 2003). This metabolite was devoid of genotoxic potential; the acute oral LD50 was between 300 and 2000 mg/kg. When DFA was

administered via the diet to Wistar rats for at least 14 days at concentrations of 500, 2000 and 8000 ppm (equating approximately to 48, 187 and 745 mg/kg body weight/day, respectively in males and 51, 201 and 800 mg/kg body weight/day, respectively in females), slight body weight decrease was observed in both sexes at 8000 ppm. In a 90-day rat study, DFA was administered in the diet administration to Wistar rats at concentrations of 200, 1000 and 6000 ppm (equating approximately to 12.7, 66.2, 380 mg/kg body weight/day, respectively in males and 15.6, 78.7, 472 mg/kg body weight/day, respectively in females). Mean body weight and food consumption were reduced at 6000 and 1000 ppm, respectively in both sexes but not at 200 ppm. When the NOAEL of 200 ppm DFA is expressed in BYI 02960 equivalents, it equates to 38 and 47 mg/kg/day in males and females, respectively. Therefore, DFA was not more toxic than BYI 02960 after subchronic administration to the rat.

BYI 02960-difluoroethyl-amino-furanone (DFEAF) is a minor plant metabolite. The acute oral LD50 in rats was higher than 2000 mg/kg, indicating that DFEAF is not more toxic than BYI 02960.

BYI 02960-CHMP ((6-chloro-3-pyridyl)methanol) is a plant metabolite. The acute oral rat LD50 was 1842 mg/kg in males and 1483 mg/kg in females. In a 90-day rat study, BYI 02960-CHMP was administered in the diet to Sprague Dawley rats (10/sex/group) at concentrations of 160, 800, 4000 and 20 000 ppm, (corresponding to 9.9, 48.9, 250.1 and 1246.6 mg/kg/day, respectively for males and 11.1, 55.9, 275.9 and 1173.7 mg/kg/day, respectively for females). Mean body weights and mean food consumption were decreased at 20000 ppm in both sexes. Based on eosinophilic intranuclear inclusions in the proximal tubular epithelium of kidneys at 20000 ppm and 4000 ppm, the no observed effects level (NOEL) was 800 ppm (48.9 mg/kg/day) in males, and 4000 ppm (275.9 mg/kg/day) in females, respectively. When the NOEL is expressed in BYI 02960 equivalents, it equates to 97.8 and 551.8 mg/kg/day, respectively. Therefore, BYI 02960-CHMP was less toxic than BYI 02960 after subchronic administration to the rat.

6-CNA (6-chloronicotinic acid) is a major soil and plant metabolite. An acute oral rat toxicity study and an Ames test were performed on this metabolite for the registration of acetamiprid. 6-CNA was not genotoxic and not acutely toxic."

RMS agrees that no separate risk assessment is required for the metabolites.

B.9.3.4 Risk assessment for terrestrial vertebrates other than birds

The risk assessment procedure follows the EFSA Guidance Document on Risk Assessment for Birds & Mammals (2009).

At Tier 1, the risk is considered acceptable, if the 'Toxicity Exposure Ratio' (TER) value pass the trigger values of ≥ 10 for acute exposure and ≥ 5 for chronic exposure.

If the TER values are below these a-priori acceptability trigger values in certain areas, a refined risk assessment based on more relevant and realistic conditions is performed for those particular areas.

Routes of exposure

The formulation is to be sprayed on hops in the field and on lettuce in glasshouses and in the field. The following routes are considered:

- direct dietary exposure: scenarios for hop and leafy vegetables – field uses only
- direct exposure via drinking water: field and glasshouse uses
- indirect exposure by consumption of earthworms and fish containing residues of BYI 02960 field and glasshouse uses

B.9.3.4.1 Exposure via feed

The first tier risk assessment calculation of is performed in the same way as for birds. The risk assessment procedure follows the EFSA Guidance Document on Risk Assessment for Birds & Mammals (2009). The methodology is described in B.9.1.5.

Mammalian generic focal species for Tier 1 risk assessment

In the field, the product is intended to be used in hop at an application rate of 1 x 0.150 kg a.i./ha, BBCH 31-75, and in lettuce at an application rate of 1 x 0.125 kg a.i./ha, BBCH 12-49. According to the EFSA Guidance Document on Risk Assessment for Birds & Mammals (2009) the following generic focal species have to be addressed in the risk assessment.

Table B.9.3.4-1 Relevant generic mammalian focal species for Tier 1 risk assessment

Crop	Growth stage (BBCH)	Generic focal species	Representative species	Shortcut value	
				For long-term RA based on RUD mean	For acute RA based on RUD 90th perc.
Hops	≥20	Small insectivorous mammal "shrew"	Common shrew	**1.9**	**5.4**
	≥ 40	Small herbivorous mammal "vole"	Common vole	**21.7**	**40.9**
	20 - 39	Small omnivorous mammal "mouse"	Wood mouse	**3.9**	**8.6**
	≥ 40	Small omnivorous mammal "mouse"	Wood mouse	2.3	5.2
Lettuce (Leafy vegetables)	10-19	Small omnivorous mammal "shrew"	Common shrew	**4.2**	**7.6**
	≥20	Small insectivorous mammal "shrew"	Common shrew	1.9	5.4
	40-49	Small herbivorous mammal "vole"	Common vole	**72.3**	**136.4**
	≥ 50	Small herbivorous mammal "vole"	Common vole	21.7	40.9
	All season	Large herbivorous mammal "lagomorph"	Rabbit	**14.3**	**35.1**
	10-49	Small omnivorous mammal "mouse"	Wood mouse	**7.8**	**17.2**
	≥ 50	Small omnivorous mammal "mouse"	Wood mouse	2.3	5.2

Bold values were used for Tier 1 risk assessment. Where the same focal species is representative for different BBCH stages, only the worst-case SV values were chosen for risk assessment.

The acute and long-term risk are calculated in the tables below.

Table B.9.3.4-2 Tier 1 acute DDD and TER calculation for mammals

Crop	Generic focal species	LD_{50} [mg/kg bw]	DDD			DDD	TER_A	Trigger
			Appl. rate [kg/ha]	SV_{90}	MAF_{90}			
BYI 02960								
Hops (≥20)	Small insectivorous mammal “shrew”	1607	0.150	5.4	1	0.81	1984	10
Hops (≥ 40)	Small herbivorous mammal "vole"			40.9		6.14	262	
Hops (20 – 39)	Small omnivorous mammal “mouse”			8.6		1.29	1246	
Lettuce (≥20)	Small insectivorous mammal “shrew”	1607	0.125	5.4	1	0.68	2381	10
Lettuce (40-49)	Small herbivorous mammal "vole"			136.4		17.05	94	
Lettuce (All season)	Large herbivorous mammal “lagomorph”			35.1		4.39	366	
Lettuce (10-49)	Small omnivorous mammal “mouse”			17.2		2.15	747	

All TER values for both crops are well above the trigger of 10 for acute exposure. Hence, no unacceptable risk is to be expected from the use of the product according to the intended use pattern.

Table B.9.3.4-3 Tier 1 long-term DDD and TER_{LT} calculation for mammals

Crop	Generic focal species	NOAEL [mg/kg bw/d]	DDD				DDD	TER_{LT}	Trigger
			Appl. rate [kg/ha]	SV_m	MAF_m	f_{TWA}			
BYI 02960									
Hops (≥20)	Small insectivorous mammal "shrew"	~~34~~ 6.4	0.150	1.9	1	0.53	0.151	~~225~~ 42	5
Hops (≥ 40)	Small herbivorous mammal "vole"			21.7			1.73	~~20~~ **3.7**	
Hops (20 – 39)	Small omnivorous mammal "mouse"			3.9			0.31	~~110~~ 21	
Lettuce (≥20)	Small insectivorous mammal "shrew"	~~34~~ 6.4	0.125	1.9	1	0.53	0.13	~~270~~ 51	5
Lettuce (40-49)	Small herbivorous mammal "vole"			72.3			4.79	~~7.1~~ **1.3**	
Lettuce (All season)	Large herbivorous mammal "lagomorph"			14.3			0.95	~~36~~ 6.8	
Lettuce (10-49)	Small omnivorous mammal "mouse"			7.8			0.52	~~66~~ 12.4	

Bold values do not meet the trigger

All TER values for both crops are above the trigger of 5 for long-term exposure, except for the generic focal species the "vole". ~~Hence, no unacceptable risk is to be expected from the use of the product according to the intended use pattern.~~

Based on the first tier endpoint of 7 mg/kg bw/d proposed originally by the notifier, a risk would be identified for small herbivorous mammals. Therefore, the notifier has proposed two further refinements:

I. measured residue data that allow refinement of the time-weighted average residue concentrations (21-d fTWA) of BYI 02960 on foliage as potential diet of small herbivorous mammals
II. a more realistic evaluation of the focal species exposure scenario (relevance of hop yards and lettuce fields for voles), based on general knowledge from literature and field study results.

<u>I) Refined DT50 of BYI 02960 on foliage</u>

According to the recommendations of the EFSA GD (2009), the Tier 1 risk assessment has been conducted with a "generic" DT50 of 10 days of BYI 02960 on all food items. However, measured residue decline data (B.7.6.2 study 1 to 4 KIIIA1 6.3.1/01-04 for lettuce, and B.9.3.2 Study IIIA

10.3.3/02 for cereals) are available that allow the calculation of compound-specific DT50 values for BYI 02960.

From the available residue decline data, it is proposed to select substrates and application types that can be considered representative for foliage as food of small herbivorous mammals in lettuce fields (i.e., spray application residue trial results) and in hop yards (spray application residue trials in young cereals as surrogate for wild undergrowth).

With these data, specific DT50 values for BYI 02960 were calculated by Scherr & Ellerich (2013),; lettuce: KIIIA 10.3.3/03; and Sur & Ellerich (2012), cereals: KIIIA 10.3.3/04) according to best practice in environmental modelling. The residue decline data were analysed with the software package KinGUI, which is a standard tool used for kinetic evaluations. In the first place, fits using the single first order (SFO) model were performed. Their quality was assessed visually and also based on statistical significance of the individual parameters. In case of clear biphasic behaviour in the respective residue data, a DFOP fit (double-first order in parallel) was also performed. Also here, visual acceptability and statistical significance were evaluated.

Residue decline data were analysed both for flupyradifurone only and for total residues of flupyradifurone including also metabolites DFA and DFEAF.

In all trials residues were determined after the second treatment, but in four trials residues were also determined after the first application and DT50 values were estimated for each decline interval.

As a result of KinGUI evaluation, 13 trials in lettuce provided SFO – DT50 values and 5 trials provided a DFOP-DT50. One trial provided an SFO-DT50 value after the first application and an DFOP-DT50 after the second application.

In young cereals, 3 trials provided SFO – DT50 values and 1 trial provided a DFOP-DT50.

Half-live (DT50) values from SFO and DFOP cannot be simply mathematically averaged in order to generate an overall DT50 to be used in time-weighted average (TWA) calculations. Since the (single) DT50 from SFO fits cannot simply be averaged with the (double) DT50 from DFOP fits, calculations of the 21-d fTWA were conducted for each of the trials, and the 17 resulting 21-d fTWA values were combined afterwards. With this approach the full set of available data can be included in the refined exposure assessment.

The TWA values themselves were thus calculated in a second step as follows. First, numerical evaluation of predicted residues in time (with timestep of 0.1 days) was performed, employing the respective kinetic type and the relevant degradation parameter(s) - DT50 value(s) and g-factor (for DFOP). These predicted residues are then used for the 21-d fTWA evaluation per data set and averaged afterwards.

Lettuce: overall, 18 residue dissipation trials with BYI 02960 were available for lettuce. In 13 of these trials, the residue dissipation could be considered according to SFO, whilst the remaining 5 trial results needed fitting with DFOP. Furthermore, one trial provided an SFO-DT50 value after the first application and an DFOP-DT50 after the second application. Since the (single) DT50 from SFO fits

cannot simply be averaged with the (double) DT50 from DFOP fits, calculations of the 21-d fTWA were conducted for each of the trials, and the 17 resulting 21-d fTWA values were combined afterwards (for each trial the value after the second application was taken). Due to the number of trials in the evaluation it is proposed to use the geometric mean 21-d fTWA = 0.17 for the refined long-term exposure assessment for small herbivorous mammals in lettuce fields (Table B.9.3.4.-4).

Geometric mean 21-d f_{TWA} (only ftwa values after second application included)					**0.17**

However, some uncertainty remains on whether this value is applicable to the full application period. In the GAP, application in lettuce is proposed between BBCH 12-49. The notifier states that the inclusion of the evaluation of some residue decline after the first application and the fact that there is no large difference between the decline after the first and the second application, addresses the question of potential impact of the application stage on the decline curves. To investigate this statement, RMS checked the lettuce trials to see at which BBCH-stages they were performed. See Table B.9.3.4-5.

The table shows that only one of the four doubly analysed trials was performed at a relatively early BBCH stage. In the view of the RMS, this is not enough proof that the residue decline trials really cover also early application stages (from BBCH 12). If these data are used in a refined risk assessment, this issue should be addressed further.

Cereals as surrogate for undergrowth in hop yards: overall, 4 residue dissipation trials with BYI 02960 were available for young cereals. In 3 of these trials, the residue dissipation could be considered according to SFO, whilst in the remaining trial results needed fitting with DFOP. Since the (single) DT50 from SFO fits cannot simply be averaged with the (double) DT50 from DFOP fits, calculations of the 21-d fTWA were conducted for each of the trials, and the 4 resulting 21-d fTWA values were combined afterwards. Due to the number of trials in the evaluation it is proposed to select the median 21-d fTWA = 0.15 for the refined long-term exposure assessment for small herbivorous mammals feeding on undergrowth in hop yards (Table B.9.4.3-5). The trials were performed at BBCH 25-29, meaning that the cereal plants were in the tillering stage. RMS considers this reasonably representative for the grass that is expected to form the undergrowth vegetation of hop plantations.

Table B.9.3.4-5 DT_{50} and 21-d f_{TWA} for residue dissipation of total flupyradifurone on young cereals

R04	10-2958-04, S-EU	3.15	-	-	0.21
Median 21-d f_{TWA}					**0.15**

The two residue data sets result in very similar 21-d f_{TWA} values (0.17 and 0.15).
~~However, the residue decline data are not used, because based on the NOEAL of 34 mg/kg bw/d, a refined risk assessment is not necessary.~~

Expert consultation during Pesticide Peer Review meeting 124, ecotoxicology, December 2014:

The approach described above, for deriving overall ftwa values from the lettuce and cereal trials, was discussed in the expert meeting. It was questioned whether the approach taken by the RMS was reasonable as a refinement. The studies performed on lettuce were questioned as food items could be weeds including monocots. The RMS highlighted that trials on cereals were also available and the difference in the fTWA was minor indicating not too dissimilar speed of degradation/dissipation. It was noted that 18 trials were available for lettuce and only 4 for cereals. It was discussed whether the scenarios in the GD cover mammals consuming the lettuce crop plants in addition to weeds. Experts noted that different FIR would be needed for a lettuce scenario. The experts agreed that, when refining the assessment, the food items taken by the focal species should be considered.

The representativeness of the studies used was discussed noting that the studies were not performed at the correct growth stage. The lettuce trials were performed at BBCH 17 to 46 whereas the GAP is BBCH 12 to 49 (lettuce). The RMS considered this in the DAR and noted that the lettuce trials do not cover the entire GAP for lettuce. Furthermore, the RMS noted during the meeting that it could be that at later growth stages the dissipation is slower due to slower growth. Some experts did not consider the BBCH stage of the crop to be an issue as the studies should represent weeds in addition to the crop. Furthermore, the DT50 in the two types of trials were not too dissimilar.

The cereal trials were performed at BBCH 25 to 29 and therefore were at a growth stage palatable to birds and mammals. The RMS considered that this was reasonable to represent weeds. The fTWA from both trials were comparable regardless of the growth stage further supporting the use of the studies.

Overall the experts agreed that the available studies were suitable to be used for the refined assessment for the representative uses.

It was discussed how the fTWA values should be used in the risk assessment (geomean, pooled, lower, two assessments). The geomean was questioned as it does not result in a worst case value but then the RMS noted that there were more than ten values indicating that the geomean was reasonable (NL approach). The RMS also noted that the studies needed to cover the entire EU. Some studies were performed in NEU and SEU, no differences were noted. Overall, the experts considered that the data were sufficient for N and SEU. The RMS suggested that the data could be pooled and then the geomean from the pooled data used. The experts noted that pooling data should be done with care and therefore it is difficult to agree on the basis of the available raw data. It was agreed that the RMS should pool the data but check statistically significant differences between the two data sets (lettuce

crop vs. cereals and N vs. SEU) whether the pooled data are ok. If so, then the geomean can be taken. If not, then the experts considered that separate risk assessments may be required.

It was agreed that the data was suitable for all weed types and lettuce crop plants given that the data cover monocots and dicots and that the DT50 may not depend on the structure of the plant.

On the basis of the above, the RMS needs to update the risk assessment using the appropriate fTWA.

It was noted that the approach in which the 21-d ftwa is calculated from measurements which started at the last application (in trials with two applications) is acceptable for the current GAP, since this has only one application per year. It was discussed that it may not cover GAPs which have multiple applications, as the 21-d exposure window may be higher at an earlier stage. Therefore, for other GAPs it needs to be carefully considered how to use these data.

The differences between the data sets were checked by the RMS (t-test, unequal variance, two-sided): lettuce N-lettuce S; cereal N- cereal S (note that only four trials were available here so this exercise is less useful); all trials lettuce-cereals; all trials N-S. Result: P>0.1 in all cases. Therefore, the data can be pooled and the overal geometric mean can be taken for all weed types and lettuce crop plants. Thus, in the refined risk assessment for the small herbivorous mammal “vole”, an ftwa of 0.164 can used for the representative uses.

The shortcut value which was used in the first tier calculation is calculated as SV = FIR/bw * deposition factor * RUD. In the first tier table from the EFSA GD (Appendix A), the shortcut value for the “vole” in “leafy vegetables” at BBCH 40-49 is 72.3. This is derived as follows:

FIR/bw = 1.33 (based on 100% grass intake and 25 g body weight)

Deposition factor = 1 for lettuce (no interception), 0.3 for hops (70% interception)

RUD = 54.2 (default RUD from “grass + cereal” database).

In the refined risk assessment, it needs to be considered if these values are still appropiate.

The deposition values are dependent on crop stage and therefore still relevant. Note that for lettuce, interception should not be taken into account at any stage for the part of the diet that consists of crop plants.

The “vole” foraging in lettuce fields may feed on all types of plants, not only grass. The FIR/bw for a 25 g mammal feeding 100% on ‘non-grass herbs’ is 1.61 (calculated according to Appendix G). Therefore, the first tier FIR/bw of 1.33 may slightly underestimate the risk. However, the default RUD value for the food category “non-grass herbs” is 28.7, which is almost half that of “grass”. Therefore, the calculations based only on 100% “grass” intake are clearly worst-case even though the diet composition of the “vole” in lettuce fields is not known, and as long as the default RUDs are used it is not necessary to use a different FIR/bw in the refined calculations.

Table B.9.3.4-7 Refined long-term DDD and TER_{LT} calculation for the "vole"

Crop	Generic focal species	NOAEL [mg/kg bw/d]	DDD				DDD	TER_{LT}	Trigger
			Appl. rate [kg/ha]	SV_m	MAF_m	f_{TWA}			
BYI 02960									
Hops (≥ 40)	Small herbivorous mammal "vole"	6.4	0.150	21.7	1	0.164	0.53	12	5
Lettuce (40-49)	Small herbivorous mammal "vole"	6.4	0.125	72.3	1	0.164	1.48	**4.3**	5

Bold values do not meet the trigger

The refined TER value for the use in hops is above the trigger, indicating acceptable risk. For the use in lettuce the TER is below the trigger. The applicant provided a statement to address the risk.

Relevance of the "vole" scenario in hops and lettuce fields

The notifier submitted a statement which is presented without modifications below. Please note that the TER values are based on the worst-case endpoint of 7.8 mg/kg bw/d.

"*The risk to wild mammals from the use of BYI 02960 has been evaluated according to the Tier 1 scenarios provided in the EFSA GD. These scenarios include small insectivorous mammals ("shrew"), small omnivorous mammals ("mouse"), large herbivorous mammals ("lagomorph"), and small herbivorous mammals ("vole").*

*Whilst all other scenarios demonstrated adequate margins of safety, even with the worst case settings of a Tier 1 assessment, the scenario "vole" resulted in Tier 1 TERLT values of 4.5 and 1.6 for the uses in hop and lettuce, respectively. These Tier 1 TERLT values for voles exceed a threshold of 1, indicating that some margins of safety exist even under the worst case settings applied at Tier 1. Quantitative refinement elements (refined reproductive risk assessment endpoint 39.23 mg/kg/bw/d; measured residue decline DT50 resulting in 21-d fTWA = 0.19) that have been introduced above allow a re-calculation of the Tier 2 TERLT values that include margins of safety clearly in excess of the a-priori acceptability trigger of 5 (*values not shown here*).*

Thus, a quantitative refinement at the level of individual exposure and risk can be conducted to demonstrate acceptable risk at the level of individual voles.

However, the protection goal in ecotoxicology aims ultimately at protection of populations rather than individuals. Therefore the section below is intended to additionally evaluate the risk to vole populations from exposure to BYI 02960 after application in hop or lettuce fields. This evaluation is based on the

well known biology and ecology of Common voles (Microtus arvalis) as the representative species "behind" the generic focal species scenario "vole", and complemented with a targeted field study in hop yards.

Exposure of Populations

The optimum or prime habitat of the common vole requires permanent vegetation cover and includes grassland or perennial crops such as alfalfa and clover fields. Common voles also occur in sub-optimal (secondary) habitats such as arable land. However, only prime habitats harbor permanent vole populations and are essential for the survival of common vole populations. Secondary habitats are only transiently populated, with regular population declines up to extinction during agronomic operations (e.g., ploughing or harvest), or over winter.

Wherever the species occurs; the population densities of Common voles vary seasonally, with regular mass occurrences being followed by a population break-down which can even lead to local extinction.

Spring crops like lettuce fields are not populated during winter, would not provide much cover against predation and could thus be colonized only from adjacent prime habitats at times of high population density. Spring sown vegetable fields would therefore not belong to the potential prime habitats of Common voles (e.g. Spitz, 1977[3]).

A field study conducted in hop yards in Germany (KIIIA1 10.3.3/01) also confirms that the treated area does not harbor significant proportions of the local vole populations.

Thus, any effect from exposure of voles in areas treated with BYI 02960 would be of low, if any, importance on the local population level which depends on the voles living outside of the lettuce fields or the hop yards.

Vulnerability of populations:

The failure to demonstrate TERLT > 5 for voles is not a rare event, due to the worst case combination of factors involved in the scenario. Actually, in regard of theoretical exposure of individual animals, the vole scenarios are nearly always the most critical all over the EFSA GD (2009). However, with regard of the vulnerability of vole populations, the vole scenario is probably the least critical.

The Joint Working Group on the Guidance Document on Risk Assessment for Birds & Mammals (SANCO 10997/2009) has already raised the question on the "need for the vole scenario… given the resilience of the vole populations"; i.e. well-known fact that voles are able to recover after large population breakdowns, or despite eradication programs with targeted rodenticide use (for recent evaluations see e.g.. Jacob & Tkadlec 2010[4], or Jokic et al. 2010[5]).

---

[3] Spitz F (1977), Le campagnol des champs (*Microtus arvalis* (Pallas)) en Europe. EPPO Bulletin 7:156-175. BCS Edition no. M-228600-01-1

[4] Jacob & Tkadlec (2010), Rodent outbreaks in Europe: dynamics and damage. In:Singleton et al. (Eds): Rodent outbreaks: Ecology and Impacts.,p: 217-233. BCS Edition no: M-427173-01-1

[5] Jokic G, Vuksa P & Vuksa M (2010), Comparative efficacy of conventional and new rodenticides against Microtus arvalis (Pallas, 1778) in wheat and alfalfa crops. Crop Protection 29: 487-491. BCS Edition no: M-427179-01-1

This potential for recovery of Common voles is extraordinarily large, due to the ability of Common voles to achieve high population numbers within short periods of time thanks to the reproduction biology of the species (e.g. Lauenstein 1979[6], Jacob 2003[7]):

- *the potentially highest number of young per litter ranges between 12 and 13. The weight of a litter is about 53% of the females weight*
- *average number of young per litter in the field is about 7*
- *gestation period is about 20 days in the field*
- *successful mating occurs when young females are not yet weaned*
- *long reproduction period including occasional winter reproduction*

The most straightforward application of the conclusion by the Joint Working Group on the Guidance Document on Risk Assessment for Birds & Mammals (SANCO 10997/2009) (questioning the "need for the vole scenario… given the resilience of the vole populations)" would be that the failure to meet the a-priori acceptability trigger for long-term exposure of individual voles is not to be considered as problematic as long as the TER trigger for the other wild mammal scenarios reach the respective TER trigger.

This is clearly the case for exposure of wild mammals to BYI 02960.

Small herbivorous mammals in hops

A targeted field study has been conducted in hop yards in Germany (KIIIA1 10.3.3/01).

Live trapping revealed that hop yards do not harbor significant proportions of small herbivorous mammals (Common vole, Field vole or Bank vole), as only 0.09% (3 of 3272) of the individuals of the local vole populations was recorded in-field. Radio-tracking confirmed that voles make very little use of hop yards as feeding habitat. Only one of 10 voles (1 of 5 common voles) potentially spent foraging time in a hop yard. This individual was only trapped once, thus considered a disperser rather than part of a local in-field population.

Overall the results of the study do not confirm that the generic focal species scenario of "small herbivorous mammals (vole)" provided in the EFSA GD 2009 would be relevant for hop yards. To the contrary, a very low number of individual voles (< 0.1%) would be exposed on hop yards and the risk on local populations from effects on these individuals would be negligible.

Small herbivorous mammals in leafy vegetables

The prime habitat of voles is grassland but the species can also be found in cultivated areas. Stable populations can be developed in multi-annual crops, particularly clover/alfalfa fields which perfectly match the species ecological needs. Whilst autumn sown fields might serve as overwintering habitat, spring sown fields would only be colonized later in the season (summer) and only during periods of high population density, then representing rather a "sink" than a "source" habitat for the local populations). "

6 Lauenstein G (1979), Zur Problematik der Bekämpfung von Feldmäusen (Microtus arvalis Pall.)) auf Grünland. Zeitschrift für angewandte Zoologie 66: 35-59. BCS Edition no M-419441-01-1

7 Jacob J (2003), Short-term effects of farming practices on populations of common voles. Agriculture, Ecosystems and Environment 95: 321-325. BCS Edition no. M-415511-01-1

Response RMS: The first tier risk assessment based on the ecologically relevant endpoint of 34 mg/kg bw/d was acceptable in the original DAR, so the public literature referred to was not evaluated. The monitoring trial in hop fields was however evaluated above (Study IIIA, 10.3.3/01).
The live trapping of mammals showed that they preferred the natural habitats instead of the hop yard. The wood mouse was the most abundant species inside the hop yard and was the only species tracked regularly inside the hop yard. Five common voles were radiotracked; one of those spent all its time in the hop yard. This individual, a fertile male, used the habitat hop yard and spent 100% of the 24 h telemetry in it. This individual seemed to be a so-called disperser trapped on study site 4, it was the only common vole trapped on this site. In late July the undersown crops Raphanus sativa, Galinsoga spec, and Chenopodiaceae were already high and therefore the predation risk inside the hop yard decreased. The population densities of common voles in the surroundings in late July was high and the need for new territories increased. These factors indicate that this individual was migrating and used the hop yard not as a sustainable habitat. However, this finding means that common voles can use hop fields as feeding habitat, at least occasionally. Therefore, RMS does not agree with the notifier that the study shows that the common vole is not a relevant species in hop fields.
It should also be noted that the results from this study (for both mammals and birds) are based on hop yards close to nature areas. It is not clear if the same focal species can be used for hop yards in an intensively cultivated area, if present at all. Mammal trapping was only conducted in the hop yards close to nature, therefore it is not possible to compare species abundance between plots in intensively cultivated area and plots close to nature areas.
If the study is used in a refined risk assessment, these remarks should be taken into account.

Furthermore, in case of higher tier, EFSA (2009) requires an uncertainty analysis of the refinements (see 6.8 and 6.9).This is however not available in the dossier. Should a refined risk assessment become necessary (e.g. by change of the endpoint after peer review), an uncertainty analysis should be provided, in the tabular form recommended by EFSA.

Based on the new long-term endpoint for mammals, the TER for the small herbivorous mammal “vole” from the use of the a.s. in lettuce is 4.3, which is below the trigger of 5. The notifier questions the relevance of the “vole” scenario in general. This issue should be considered by a dedicated EFSA working group or the PPR panel. As long as the guidance document includes the vole scenario, it has to be taken into account. Non-relevance of a species (group) can be shown with field monitoring data, but these are not available for mammals in lettuce fields. Population effects can be investigated with field effect data and/or population modelling, but these are not available either. Based on the available data, a risk to the “vole” cannot be excluded. It is noted that the TER is not far below the trigger, that the only refinement included is one on residue dissipation, that the TER is calculated with the lowest

available long-term endpoint which is based on <10% lower bodyweight at the next level, and that the diet composition use in the calculations is worst-case.

B.9.3.4.2 Exposure via drinking water

An assessment of the risk potentially posed by consumption of contaminated drinking water is required according to the EFSA Guidance Document for Birds and Mammals (2009).
Two scenarios were identified as relevant for assessing the risk of pesticides via drinking water to birds and mammals:

- Leaf scenario, only relevant for birds possibly drinking water from puddles in leaf whorls after application of a pesticide to a crop and subsequent rainfall or irrigation; not relevant for mammals.
- Puddle scenario. Birds and mammals taking water from puddles formed on the soil surface of a field when a (heavy) rainfall event follows the application of a pesticide to a crop or bare soil. This scenario is relevant for all types of applications that may cause contamination of soil and only for long-term exposure. A risk assessment is performed below.

Risk assessment for the puddle scenario (field use in hop and lettuce):

An "escape clause" recommended in the EFSA Guidance Document for Birds and Mammals (2009) allows for screening the need for a quantitative risk assessment by a comparison between the application rate and the toxicity of the respective substance. This escape clause specifies that "*due to the characteristics of the exposure scenario in connection with the standard assumptions for water uptake by animals …, no specific calculations of exposure and TER are necessary when the ratio of effective application rate (= application rate x MAF) (in g/ha) to relevant endpoint (in mg/kg bw/d) does not exceed 50 in the case of less sorptive substances (Koc < 500 L/kg) or 3000 in the case of more sorptive substances (Koc ≥ 500 L/kg).*" [8].

Table B.3.4-~~6~~8 Evaluation of potential concern for exposure of mammals drinking water from puddles (escape clause)

Compound	Koc [mL/g]	Application rate * MAF [g a.i./ha]	LD50 or NO(A)EL [mg a.i./ kg bw/d]	Ratio (Application rate * MAF) / NO(A)EL	"Escape clause" No concern if ratio	Conclusion
BYI 02960	98.4 [1)]	150 [2)] x 1	1607	0.09	≤ 50	No concern
			~~34~~ 6.4	~~4.4~~ 23	≤ 50	No concern

[8] EFSA (2009): Guidance Document on Risk Assessment for Birds & Mammals on request from EFSA, p. 66

1) Arithmetic mean of ten K_{OC} values (see B.8)
2) Worst-case application rate in hops

This evaluation confirms that the risk for mammals from drinking from puddles that may contain residues from the use of product is acceptable.

B.9.3.4.3 Bioaccumulation and food chain behaviour: Indirect exposure via contaminated worms or fish

Substances with a high bioaccumulation potential could theoretically bear a risk of secondary poisoning for mammals if feeding on contaminated prey like fish or earthworms. For organic chemicals, a log POW > 3 is used to trigger an in-depth evaluation of the potential for bioaccumulation. As shown in B.9.1.5.3, neither the active ingredient nor any of its metabolites has a log Pow above 3 and the potential of bioaccumulation is considered to be very low. Hence, there is no need to evaluate potential effects of secondary poisoning of mammals.

test substance	:	BYI 02960; batch code BYI 0296-01-01*; original batch no. NLL 7780-44-6;	LD50 (oral)	:	1.2 µg a.s./bee
a.s. content	:	99.5%	LD50 (contact)	:	122.8 µg a.s./bee

*The batch used was originally not reported in Document J (confidential information). The applicant submitted additional information (which is included in the revised Volume 4) which shows that this batch is equivalent to the technical specification of flupyradifurone.

Methods

A 48-hour acute oral and contact toxicity test on honeybees (*Apis mellifera*) was conducted with BYI 02960. In the oral toxicity test 3 replicates of ten bees each per concentration were exposed to a nominal dose of 0.16, 0.31, 0.63, 1.3, 2.5 and 5.0 µg a.s./bee, with untreated (50% sugar syrup in water), solvent (50% sugar syrup, 5% acetone, 45% water) and positive control (dimethoate, 0.05, 0.08, 0.15 and 0.30 µg a.s./bee). In the contact toxicity test, 3 replicates of ten bees each were exposed to a dose of 12.5, 25, 50, 100 and 200 µg a.s./bee, with water treated control (tap water with 0.5% Adhäsit), solvent control (acetone) and positive control (dimethoate, 0.10, 0.15, 0.20 and 0.30 µg a.s./bee). Due to increasing mortality between 24 and 48 hours, and between 48 and 72 hours, the contact test was prolonged to 96 hours.

Results

In the oral toxicity test, the actual consumed dose was 0.17, 0.34, 0.68, 1.3, 2.1 and 2.8 µg a.s./bee. In the oral toxicity test, discoordinated movements and apathy occurred at 0.68, 1.3, 2.1 and 2.8 µg a.s./bee. In the contact toxicity test, discoordinated movements occurred at 50, 100 and 200 µg a.s./bee. The positive control gave the expected response in both tests (24-h oral and contact LD50 0.13 and 0.17 µg a.s./bee, respectively). The remaining results are summarised in the Table below.

Table B.9.4.1.1-01 The acute oral and contact toxicity of BYI 02960 to honeybees (*Apis mellifera*)

Contact toxicity test					Oral toxicity test		
dosage	Mortality [%]				dosage	Mortality [%]	
[µg a.i./ bee]	24 h	48 h	72 h	96 h	[µg a.i./ bee]	24 h	48 h
test item					test item		
200.0	0.0	36.7	60.0	73.3	2.8	100.0	100.0
100.0	3.3	23.3	33.3	36.7	2.1	90.0	90.0
50.0	6.7	6.7	20.0	23.3	1.3	53.3	53.3
25.0	0.0	6.7	13.3	13.3	0.68	6.7	6.7
12.5	0.0	0.0	0.0	6.7	0.34	0.0	0.0
					0.17	0.0	3.3
LD_{50} [µg/bee]	> 200	> 200	158.4	122.8	LD_{50} [µg/bee]	1.3	1.2
NOED [µg/bee]	> 200	50.0	25.0	50.0	NOED [µg/bee]	0.68	0.68
water-treated control	0.0	0.0	6.7	10.0	water-treated control	0.0	0.0
solvent control	0.0	0.0	0.0	3.3	solvent control	0.0	0.0

The NOED was estimated using Fisher Exact Test (pairwise comparison, one-sided greater, $\alpha = 0.05$).

Conclusion

48-hour oral LD50: 1.2 µg a.s./bee; 96-h contact LD50 122.8 µg a.s./bee.

Guidelines and limitations

The test is acceptable.

GLP statement	:	Yes	dosing method	:	Contact: Stock solution in acetone; Oral: Stock solution in acetone added to sucrose solution
guideline	:	OECD 213 and OECD 214	acceptability	:	Acceptable
test substance	:	BYI02960-difluoroethyl-amino-furanone; batch BCS-CC98193-PU-01	LD50 (oral)	:	>81.5 µg pure metabolite/bee
a.s. content	:	99.2%	LD50 (contact)	:	>100 µg pure metabolite/bee

Methods

A 48-hour acute oral and contact toxicity test on honeybees (*Apis mellifera*) was conducted with BYI02960-difluoroethyl-amino-furanone (plant metabolite of BYI 02960). In the oral toxicity test 3 replicates of ten bees each per concentration were exposed to a nominal dose of 6.3, 12.5, 25, 50 and 100 µg pure metabolite/bee, with untreated (50% sugar syrup in water), solvent (50% sugar syrup, 5% acetone, 45% water) and positive control (dimethoate, 0.05, 0.08, 0.15 and 0.30 µg a.s./bee). In the contact toxicity test, 3 replicates of ten bees each were exposed to a dose of 6.3, 12.5, 25, 50 and 100 µg pure metabolite/bee, with water treated control (tap water with 0.5% Adhäsit), solvent control (acetone) and positive control (dimethoate, 0.10, 0.15, 0.20 and 0.30 µg a.s./bee).

Results

In the oral toxicity test, the actual consumed dose was 6.7, 13.7, 26.8, 54.3 and 81.5 µg pure metabolite/bee. In the oral and contact toxicity test, no behavioural effects were noted in any treatment and the controls. The positive control gave the expected response in both tests (24-h oral and contact LD50 0.13 and 0.19 µg a.s./bee, respectively). In both tests, no bee mortality occurred in any treatment and the controls, except for 1 bee (3.3%) in the contact test in the 50 µg a.s./bee treatment and the solvent control. The 48-hour oral LD50 is >81.5 µg pure metabolite/bee, the 48-h contact LD50 >100 pure metabolite/bee.

Conclusion

48-hour oral LD50 >81.5 µg pure metabolite/bee, 48-h contact LD50 >100 pure metabolite/bee.

Guidelines and limitations

The test is acceptable.

STUDY IIA, 8.7.1/03

Characteristics

reference	:	Schmitzer S. (2011)	nominal dose		Contact and oral: 100 µg pure metabolite/bee

year of execution	:	2011	exposure duration	:	48 hours
GLP statement	:	Yes	dosing method	:	Contact: Stock solution in acetone; Oral: Stock solution in acetone added to sucrose solution
guideline	:	OECD 213 and OECD 214	acceptability	:	Acceptable
test substance	:	BYI02960 - hydroxy; batch BCS-CQ74364-PU-01	LD50 (oral)	:	>105.3 µg pure metabolite/bee
a.s. content	:	95.5%	LD50 (contact)	:	>100 µg pure metabolite/bee

Methods

A 48-hour acute oral and contact toxicity limit test on honeybees (*Apis mellifera*) was conducted with BYI02960 – hydroxy (plant metabolite of BYI 02960). In the oral toxicity test 5 replicates of ten bees each were exposed to a nominal dose of 100 µg pure metabolite/bee, with untreated (50% sugar syrup in water), solvent (50% sugar syrup, 5% acetone, 45% water) and positive control (dimethoate, 0.05, 0.08, 0.15 and 0.30 µg a.s./bee). In the contact toxicity test, 5 replicates of ten bees each were exposed to a dose of 100 µg pure metabolite/bee, with water treated control (tap water with 0.5% Adhäsit), solvent control (acetone) and positive control (dimethoate, 0.10, 0.15, 0.20 and 0.30 µg a.s./bee).

Results

In the oral toxicity test, the actual consumed dose was 105.3 µg pure metabolite/bee. In the oral and contact toxicity test, no behavioural effects were noted in any treatment and the controls, except for 1 treated bee in the oral test (discoordinated movement before dying). The positive control gave the

expected response in both tests (24-h oral and contact LD50 0.12 and 0.17 µg a.s./bee, respectively). In both tests, no bee mortality occurred, except for 2 treated bees (4%) in the oral test and 1 water control bee (2%) in the contact test. The 48-hour oral LD50 is >105.3 µg pure metabolite/bee, the 48-h contact LD50 >100 pure metabolite/bee.

Conclusion

48-hour oral LD50 >105.3 µg pure metabolite/bee, 48-h contact LD50 >100 pure metabolite/bee.

Guidelines and limitations

The tests is acceptable.

B.9.4.1.2 Acute toxicity of the formulated product (IIIA 10.4.2.1 and 10.4.2.2)

STUDY IIIA, 10.4.2.1/01

Characteristics

reference	:	Schmitzer S. (2009)	nominal dose		Contact: 6.3, 12.5, 25, 50, 100 and 200 µg a.s./bee; Oral: 0.31, 0.63, 1.3, 2.5, 5.0 and 10 µg a.s./bee
type of study	:	Acute oral and contact toxicity	species	:	Honey bee (*apis mellifera*)
year of execution	:	2009	exposure duration	:	48 (oral) or 72 (contact) hours
GLP statement	:	Yes	dosing method	:	Contact: application solution in 0.5%

					Adhäsit in water; Oral: solution in 50% sucrose solution
guideline	:	OECD 213 and OECD 214	acceptability	:	Acceptable
test substance	:	BYI 02960 SL 200 G (200 g/L SL formulation), batch 2009-001253	LD50 (oral)	:	3.2 µg a.s./bee
a.s. content	:	17.0 % w/w (199.8 g/L) BYI 02960	LD50 (contact)	:	15.7 µg a.s./bee

Methods

A 48-hour acute oral and contact toxicity test on honeybees (*Apis mellifera*) was conducted with BYI 02960 SL 200 G (200 g/L SL formulation, 17.0 % w/w (199.8 g/L) BYI 02960). In the oral toxicity test 3 replicates of ten bees each per concentration were exposed to a nominal dose of 0.31, 0.63, 1.3, 2.5, 5.0 and 10 µg a.s./bee, with control (50% sugar syrup in water) and positive control (dimethoate, 0.05, 0.08, 0.15 and 0.30 µg product/bee). In the contact toxicity test, 3 replicates of ten bees each were exposed to a dose of 6.3, 12.5, 25, 50, 100 and 200 µg a.s./bee, with control (tap water with 0.5% Adhäsit) and positive control (dimethoate, 0.10, 0.15, 0.20 and 0.30 µg product/bee). Due to increasing mortality between 24 and 48 hours, the contact test was prolonged to 72 hours.

Results

The positive control gave the expected response in both tests (24-h oral and contact LD50 0.13 and 0.20 µg a.s./bee, respectively).

In the oral toxicity test, the actual consumed dose was 0.34, 0.70, 1.3, 2.6, 4.0 and 5.6 µg a.s./bee. Mortality in the control of both the oral and contact toxicity test was 0%. In the oral toxicity test, coordination problems and/or apathy occurred at 2.6-5.6 µg a.s./bee. In the contact toxicity test, a few bees at 25-200 µg a.s./bee showed abnormal behaviour (movement coordination problems and/or intensive cleaning).

In the oral toxicity test, at 0.34, 0.70, 1.3, 2.6, 4.0 and 5.6 µg a.s./bee, respectively, mortality was 0%, 0%, 0%, 16.7%, 93.3% and 93.3% after 48 hours. The 48-h oral LD50 was 3.2 (95% CI 2.3-3.9) µg a.s./bee. In the contact toxicity test, at 6.3, 12.5, 25, 50, 100 and 200 µg a.s./bee, respectively, mortality was 10.0%, 36.7%, 76.7%, 93.3%, 100% and 100% after 72 hours. The 72-h contact LD50 was 15.7 (95% CI 12.7-19.0) µg a.s./bee. NOEDs were estimated using Fisher's exact test (one-sided greater, α = 0.05): 2.6 and 6.3 µg a.s./bee in the oral and contact test, respectively.

Conclusion

48-h oral LD50 3.2 µg a.s./bee; 72-h contact LD50 15.7 µg a.s./bee.

Guidelines and limitations

The test is acceptable.

STUDY IIA, 8.7.1 /07

Characteristics

Reference	:	Vergé 2012	nominal dose		6.25, 12.5, 25, 50 and 100 µg a.s./bee
type of study	:	Acute contact toxicity	species	:	*Bombus terrestris* L.
year of execution	:	2012	duration	:	2 days
GLP statement	:	Yes	dosing method	:	solution in water
Guideline	:	OEPP/EPPO 170 (4) 2010, OECD 214 and Van der Steen (2001)	acceptability	:	Acceptable
test substance	:	Flupyradifurone SL 200 G, containing flupyradifurone 199.8 g/L analysed, density of the formulation 1.175 g/cm^3. Batch/Lot No. 2012-001530	LD50 (contact)	:	>100 µg a.s./bee
a.s. content	:	199.8 g/L			

Methods

Bombus terrestris L., young adult worker bumblebees derived from a healthy colony were exposed to test concentrations by contact exposure. Mortality and behaviour were assessed after 24 and 48 hours.

The contact test was carried out with five doses of Flupyradifurone SL 200 G. The doses were 6.25, 12.5, 25, 50 and 100 µg as/bumblebee. Bumblebees were treated by dorsal application to the thorax with an aliquot of 2 µL/bee. Test item was mixed with tap water to obtain the required doses. Three replicates per treatment with 10 bees each for contact, control and reference substance tests. Reference substance was Perfekthion (dimethoate, 411.7 g/L analysed) at 0.30 µg product/bee. Control was tap water.

Environmental conditions were: 24.4 – 25.6 ºC, 55.3 – 66.4% RH, darkness. Feeding with 50% aqueous sucrose solution. No statistics were applied.

Results

Mortality did not occur in the control nor in any of the dose levels up to and including 50 µg as/bumblebee. A mortality of 6.7% was observed at the dose level of 100 µg as/bumblebee, 24 and 48 h after application. No behavioural abnormalities or sub-lethal effects were recorded during the entire 48 hours observation period. The reference substance showed a mortality of 96.7% 24 h after application and of 100% 48 h after application.

Remarks

An LD50 value > 100 µg as/bumblebee (contact 48 h) can be used for risk assessment.

Guidelines and limitations

The test is acceptable.

**Endpoint not accepted by RMS*

Description

The chronic effects of the test item BYI 02960 on the honey bee, *Apis mellifera* L., were assessed in a 10 days continuous feeding test in the laboratory. The test was carried out with young adult worker bees derived from a healthy colony. The bees were brushed off the brood combs of one colony in order to receive young, viable adult worker bees (e.g. nurse bees). The bees were collected and distributed into the test cages one day before start of the test and were kept under test conditions over night. Bees that died during this acclimatisation period were replaced by reserve bees which were collected at the same time. During the entire test period, the bees were kept in cages made of stainless steel (base: 8.2 cm x 4 cm; height: 6 cm). The front side of the cages was equipped with a transparent pane so that the bees could be observed. The bottom of the cages consisted of a perforated board, which guaranteed sufficient air supply for the test animals. The test cages were lined with filter paper. The feeding solutions were offered to the bees in syringes fitted into the test cages. Over a period of 10 days, honey bees were exposed to 50 % (w/v) sucrose solution, containing (nominally) 100, 300, 1000, 3000 and 10000 µg as/L of the test item BYI 02960 by continuous and ad libitum feeding. All test item feeding solutions contained additionally 1% acetone. The control group was exposed to an untreated 50 % (w/v) sucrose feeding solution, also containing 1 % acetone. Mortality, sublethal effects and behavioural observations were assessed every day throughout the 10 days exposure period.

At each test item treatment level, 10 replicates of 10 honey bees each were tested (100 honey bees per test item concentration). The control group comprised 30 replicates of 10 honey bees each (300 honey bees in total). A toxic standard was not included in this test.

Samples of the stock solution and all daily prepared feeding solutions were taken directly after preparation, before start of the test. Samples were analysed by reversed-phase HPLC with Turbolon spray MS/MS-detection.

The number of dead bees in the individual test cages was recorded every day at about the same time of day during the 10 days test period. Abnormal behavioural effects and behavioural differences were assessed.

Test conditions: 24 – 25°C, 60 - 68% RH, 24 h darkness, except during observations.

The mortality of the test item treatments was corrected for control mortality, according to ABBOTT (1925), modified by SCHNEIDER-ORELLI (1947).

The consumption of feeding solution per bee/day was calculated by dividing the total daily consumption per cage by the mean number of living bees at the corresponding time interval. The mean value per treatment group as well as the daily mean food consumption per bee was calculated.

The NOEC was determined by using Fisher's Exact Test (Bonferroni-Holms corrected, one-sided, p ≤ 0.05). Data of food consumption were analysed by using the t-Test (with Bonferroni-Holms correction, one-sided, p ≤ 0.05). Statistical calculations were performed using the statistical program SAS release Version 9.2.

Results

The actual concentration of flupyradifurone in the feeding solutions, determined for each preparation day, was in the range from 90 to 95% of the nominal concentration.

A summary of endpoints is given in the table below. Table was compiled by RMS from 10 individual tables from the report. T-test was performed on cumulative mortality (%). In the table significant effects were marked for the corresponding corrected cumulative mortality.

Table 9.4.1.3-01 Mean consumption of feeding solution, mean intake of test item, mean intake accumulated over test days (mg/bee) and cumulative mortality in the BYI 02960 treatment groups and the control group (day 1-10). A negative sign indicates an increase as compared to the control.

			Test item (µg as/L) [1]				
day	**Treatment level**	**control**	**100**	**300**	**1000**	**3000**	**10000**
1	Mean consumption of feeding solution (mg/bee) *Corr. cum. mortality (%) (control mortality 3.3%)*	61	50 *-2.4*	52 *-2.4*	54 *-1.3*	64 *-1.3*	57 *-3.4*
2	Mean consumption of feeding solution (mg/bee) *Corr. cum. mortality (%) (control mortality 4.7%)*	59	48 *-3.9*	51 *-2.8*	53 *-1.8*	59 *-0.7*	61 *-4.9*

9	Mean consumption of feeding solution (mg/bee) Corr. cum. mortality *(%) (control mortality 14.7%)*	54	50 -7.9	47 -5.5	57 -6.7	49 7.4	51 -6.7
10	Mean consumption of feeding solution (mg/bee) Corr. cum. mortality *(%) (control mortality 18.0%)*	53	48 - 11.1	47 -4.9	62 -8.5	51 7.3	47 -9.8 [3]
	Overall mean consumption of sucrose solution [mg/bee/d] [2]	**57.4**	**52.4**	**50.8****	**56.4**	**58.8**	**54.9**
	Mean intake accumulated over 10 test days [µg as/bee]	**-**	**0.04**	**0.13**	**0.48**	**1.49**	**4.64**

1. The control group was fed with untreated 50 % (w/v) sucrose solution mixed with 1 % acetone; all test item treatment groups were fed with BYI 02960 treated 50 % (w/v) sucrose solution mixed with 1 % acetone
2. The mean values per cage over the test period were used as basis for the calculation of the mean consumption of feeding solution per treatment over the test period [mg/bee]. Density of the sucrose solution was in the range of 1.179-1.190 g/cm3.
3. Determined to be the NOEC (not significantly different compared to the control) (Fisher's Exact Test (Bonferroni-Holms corrected, one-sided, p ≤ 0.05))

** Significantly reduced compared to the control group (t-Test with Bonferroni-Holms correction, one-sided, p ≤ 0.05)

After 10 days of continuous exposure, mortality at all test item treatment levels was not significantly increased compared to the control group.

According to the author, at all test item treatment levels, no significant sublethal effects or behavioural abnormalities were observed throughout the entire test period. The highest test item treatment level of 10000 µg as/L was determined to be the NOEC (Fisher's Exact Test; Bonferroni-Holms corrected, one-sided, $p \leq 0.05$).

At the 300 µg as/L test item treatment level, the mean food consumption per bee was slightly, although statistically significantly reduced when compared to the food consumption of the control group (t-Test with Bonferroni-Holms correction, one-sided, $p \leq 0.05$). However, at all other dose levels, higher and lower than 300 µg as/L (i.e. 100, 1000, 3000 and 10000 µg as/L), the food consumption was not statistically significantly different when compared to the food consumption of the control group.

The accumulated nominal intake of the test item via BYI 02960-treated sucrose solution was 0.04, 0.13, 0.48, 1.49 and 4.64 µg as/bee after 10 days of continuous exposure.

Remarks by RMS

The author states that a toxic standard was not included in this test, since a toxic reference substance had not been defined or validated for this type of study. The mortality in the control is very high (18%) compared to the control mortality in studies 8.16.1/02 – 8.16.1/06 with the metabolites (2% in studies 02 and 03, and 4 % in studies 04, 05 and 06). Both treatment and control mortality in this study are clearly higher than in the metabolite studies. It is difficult to compare the control results of the metabolite studies with the treatment results of the a.s. since the studies are performed in different years (2010 for the a.s., 2011 for the metabolites).

It is acknowledged that no harmonised guideline is as yet available for this type of study. However, recent descriptions of this study (e.g. in Appendix M of the EFSA GD on bees and Appendix O of the final version of the EFSA GD on bees (published July 2013), recommendations on the 10-d oral feeding study on adult honeybees include a control mortality of <15%.

Furthermore, in the treatment of this study, there are a number of bees that are affected (a, (bees still upright and attempting to walk but showing signs of reduced coordination) or show signs of apathy (ap, bees show only low or delayed reactions to stimulation [i.e. light, air blow] bees are either sitting motionless in the cage or walk but not correctly). These effect appear mostly from day 7 onwards but otherwise there is no clear pattern. Few bees were affected, affected bees usually show no symtoms anymore on the next day, and there seems to be no dose-respons.

The table shows the number of bees with sublethal effects. Moribund bees were also recorded but it has to be taken into account that the moribund bees usually die in the following days.

Table 9.4.1.3-02 Sublethal effects during the test

Test item (µg as/L)	Total number of bees (affected+apathic) – (moribund) per tested concentration									
	d1	d2	d3	d4	d5	d6	d7	d8	d9	d10
0	0 - 0	0 - 1	0 - 1	0 - 2	0 - 1	0 - 1	0 - 0	0 - 0	0 - 1	0 - 0
100	0 - 0	0 - 0	0 - 0	0 - 0	0 - 0	0 - 0	0 - 0	0 - 1	1 - 0	1 - 0

300	0 - 0	0 - 0	0 - 0	0 - 0	0 - 0	0 - 0	1 - 2	1 - 1	1 - 0	1 - 0
1000	0 - 0	0 - 0	0 - 0	0 - 0	0 - 0	0 - 0	0 - 0	0 - 0	0 - 0	3 - 1
3000	0 - 0	0 - 0	0 - 0	0 - 1	0 - 0	0 - 0	0 - 0	1 - 0	1 - 1	3 - 0
10000	0 - 0	0 - 0	0 - 0	1 - 0	0 - 0	0 - 0	0 - 0	2 - 0	0 - 0	2 - 0

In the control affected or apathetic bees were never seen. It can therefore not be concluded that there are no effects on behaviour (it is acknowledged that it is not yet clear what the impact of the sublethal effects on behaviour is on bee colonies).

Based on the high control mortality and the uncertainty about the sublethal effects, this study is not accepted. Therefore, the applicant performed a new 10-d oral study with adult honey bees, see below.

Study IIA 8.16.1/09

Characteristics

Reference	:	Gladbach, Theis et al., 2013	nominal dose	:	10, 16, 26, 41 and 66 mg as/kg
Type of study	:	honey bees, 10 days feeding test	species	:	Honey bee (*Apis mellifera*)
Year of execution	:	2013	exposure duration	:	10 d
GLP statement	:	yes	dosing method	:	chronic oral toxicity – continuous feeding test
Guideline	:	no specific guideline available	Acceptability	:	Acceptable
Test substance	:	BYI 02960, Batch no: BYI 02960-02-04	NOEC	:	26 mg/kg diet / 0.79 µg/bee/day
a.s. content	:	98.0%	LC50		61.1 mg/kg diet / 1.83 µg/bee/day

Description

The chronic effects of the test item BYI 02960 on the honey bee, Apis mellifera L., were assessed in a 10 days continuous feeding test in the laboratory. The test was carried out with young adult worker bees derived from a healthy colony. Four days prior to test start, three brood combs containing capped cells with an expected hatch on the same day were collected from three honey bee colonies and transferred into a ventilated plexi-glass containment, placed inside a climatic chamber in the laboratory. The brood combs contained some honey as food for the freshly hatched bees. One day prior to test start of the test, the 0 - 3 days old bees were collected from the plexi-glass containment and transferred to the test cages and kept under test conditions until test start.

During the entire test period, the bees were kept in cages made of stainless steel (85 x 45 x 65 mm [length x width x height]). The front side of the cages was equipped with a transparent pane so that the bees could be observed. The bottom of the cages consisted of a perforated board, which guaranteed sufficient air supply for the test animals. The test cages were lined with filter paper. The feeding solutions were offered to the bees in syringes fitted into the test cages.

Over a period of 10 days, honey bees were exposed to 50 % (w/v) aqueous sugar solution, containing five concentrations (nominally) of the test item BYI 02960: 10, 16, 26, 41 and 66 mg as/kg, by continuous and ad libitum feeding. All test item feeding solutions contained additionally 1% acetone. The control group was exposed to an untreated 50 % (w/v) aqueous sugar feeding solution, also containing 1 % acetone. Mortality, sublethal effects and behaviour were assessed every day

throughout the 10 days exposure period. Test conditions: 31.8 – 33.1°C (average: 32.9°C), 37.3 – 76.1 % (average 72.3 %), 24 h darkness, except during observations.

Chemical analysis

At each test item treatment level and the control, 10 replicates of 10 honey bees each were tested (100 honey bees per test item concentration). A toxic standard was not included in this test.
Per individual feeding day and per individual treatment level and control, samples of approximately 10 mL and retain samples of about 5 mL were taken directly after the preparation of the respective treatment-specific feeding solutions (i.e. per test item treatment level and control, respectively, at D1 – D10). Samples were analysed by HPLC coupled with MS/MS-detection and electrospray ionizations (ESI).

Calculations and statistics

The mortality of the test item treatments was corrected for control mortality, according to ABBOTT (1925), modified by SCHNEIDER-ORELLI (1947). The consumption of feeding solution per bee/day was calculated by dividing the total daily consumption per cage by the mean number of living bees at the corresponding time interval. The mean value per treatment group as well as the daily mean food consumption per bee was calculated. Actual daily intake and cumulative intake of the test substance per bee were calculated from the consumption data and chemical analysis. The NOEC was determined by using Fisher's Exact Test (Bonferroni corrected, one-sided, $p \leq 0.05$) . The LC50 / LDD50 was determined by using Probit analysis with linear, maximum likelihood regression. Data on food consumption were statistically analysed by using the Williams Multiple Sequential t-test Procedure, $p \leq 0.05$. All statistical calculations were made by using the statistical program "ToxRat Professional", Version 2.10.

Results

The actual concentration of flupyradifurone in the feeding solutions, determined for each preparation day, was in the range from 80 to 114% of the nominal concentration (mean 103%).
A summary of endpoints is given in the table below. Table was compiled by RMS from individual tables from the report.

Table B.9.4.1.3-03 Mean consumption of feeding solution, mean intake of test item, mean intake accumulated over test days and cumulative mortality in the BYI 02960 treatment groups and the control group (day 1-10). A negative sign indicates an increase as compared to the control.

	Overall mean consumption of sucrose solution [mg/bee/d] [2]	32.6	32.8	31.3	30.6	27.1*	30.4*
	Mean daily dose per bee over 10 test days [µg as/bee/day]	-	0.33	0.50	0.79	1.11	2.01
	Cumulative mortality after ten test days [%]	0.0	0.0	0.0	0.0	13.0**	58.4**

1: The control group was fed with untreated 50 % (w/v) sucrose solution mixed with 1 % acetone; all test item treatment groups were fed with BYI 02960 treated 50 % (w/v) sucrose solution mixed with 1 % acetone

2 The daily consumption per cage throughout the test period was used as basis for the calculation of the mean consumption of feeding solution per treatment level over the test period

* Statistically significantly lower compared to control (Williams Multiple Sequential t-test, α = 0.05, one-sided smaller)

** Statistically significantly higher compared to control (Fisher's Exact Test, Bonferroni corrected, one-sided, p ≤ 0.05)

After 10 days of continuous exposure, mortality at the two highest test item treatment levels was significantly increased as compared to the mortality in the control group.

At the two highest test item treatment levels, sublethal effects or behavioural abnormalities were observed. The NOEC was determined to be 26 mg as/kg diet (Fisher's Exact Test; Bonferroni corrected, one-sided, p ≤ 0.05).

At the two highest test item treatment levels, the mean food consumption per bee over ten days was statistically significantly reduced when compared to the food consumption of the control group (Williams Multiple Sequential t-test, α = 0.05, one-sided smaller). At all other dose levels the food consumption was not statistically significantly different when compared to the food consumption of the control group.

The nominal intake of the test item via BYI 02960-treated sucrose solution was 0.0, 0.33, 0.50, 0.79, 1.11 and 2.01 µg as/bee per day over 10 days of continuous exposure. The total accumulated dose over the 10-days period was 3.28, 5.01, 7.94, 11.13 and 20.10 µg as/bee.

Remarks by RMS

The author states that a toxic standard was not included in this test, since a toxic reference substance had not been defined or validated for this type of study. This is acceptable.

In the control and the three lowest test concentrations (10, 16 and 26 mg as/kg diet), no mortality occurred (0.0%) after ten days of continuous exposure. In the control and the three lowest test concentrations there were no affected/apathic animals with the exception of one animal (at 26 mg as/kg diet) that showed no symptoms the day after. It can therefore be concluded that the NOEC for mortality, food intake and behaviour is 26 mg as/kg diet. The results, a NOEC of 26 mg as/kg diet and an LC50 value of 61.1 mg as/kg diet, can be used for risk assessment. The NOEC-level corresponds with an average daily intake of 0.79 µg as/bee/day and an accumulated dose over 10 days of 7.94 µg/bee, the LD50 with an average daily intake of 1.83 µg as/bee/day.

Study IIA 8.16.1 /02

Characteristics

Reference	:	Kling, A. (2012)	nominal dose		10000 µg as/L (limit test)
type of study	:	honeybees, 10 days feeding test	species	:	Honey bee (*Apis mellifera*)
year of execution	:	2011	exposure duration	:	10 d
GLP statement	:	Yes	dosing method	:	chronic oral toxicity – continuous feeding test
Guideline	:	No specific guideline available	acceptability	:	Acceptable
test substance	:	BYI 02960-DFEAF, Batch no. BCS-CC98193-01-03	NOEC	:	≥ 10000 µg as/L / ≥ 0.435 µg/bee/day
a.s. content	:	98.9%	LC50		> 10000 µg as/L / > 0.435 µg/bee/day

Description

The chronic effects of the test item BYI 02960-DFEAF, a metabolite of flupyradifurone, on the honey bee, *Apis mellifera* L., were assessed in a 10 days continuous feeding test in the laboratory. The test was carried out with young adult worker bees derived from a healthy colony. The bees were brushed off the brood combs of one colony in order to receive young, viable adult worker bees (e.g. nurse bees). The bees were collected and distributed into the test cages one day before start of the test and were kept under test conditions over night. Bees which died during this acclimatisation period were replaced by reserve bees which were collected at the same time. During the entire test period, the bees were kept in cages made of stainless steel (base: 8.2 cm x 4 cm; height: 6 cm). The front side of the cages was equipped with a transparent pane so that the bees could be observed. The bottom of the cages consisted of a perforated board, which guaranteed sufficient air supply for the test animals. The test cages were lined with filter paper. The feeding solutions were offered to the bees in syringes fitted into the test cages.

Ten replicates of 10 honey bees each were tested (in total 100 honey bees per test item concentration). The control group comprised 30 replicates of 10 honey bees each (in total 300 honey bees). A toxic standard was not included.

Samples of the stock solution and all feeding solutions were taken directly after preparation for subsequent residue analysis. Samples were analysed by reversed-phase HPLC with Turbolon spray MS/MS-detection.

The number of dead bees in the individual test cages was recorded every day at about the same time of day during the 10 days test period. Abnormal behavioural effects and behavioural differences were assessed.

Test conditions: 25.1 – 25.8°C, 51.2 – 69.4% RH, 24 h darkness, except during observations.

The mortality of the test item treatments was corrected for control mortality, according to ABBOTT (1925), modified by SCHNEIDER-ORELLI (1947).

The consumption of feeding solution per bee/day was calculated by dividing the total daily consumption per cage by the mean number of living bees at the corresponding time interval. The mean value per treatment group as well as the daily mean food consumption per bee was calculated.

The NOEC was determined by using Fisher's Exact Test (Bonferroni-Holms corrected, one-sided, $p \leq 0.05$). Data of food consumption were analysed by using the t-Test (with Bonferroni-Holms correction, one-sided, $p \leq 0.05$). If the data deviated from the normal distribution, statistical analysis was performed by using the Mann Whitney – U test. Statistical calculations were made by using the statistical program SAS release Version 9.2.

Results

The actual concentration of BYI 02960-DFEAF in the feeding solutions, determined for each preparation day, was in the range from 97 to 110% of the nominal concentration (mean 103%).

A summary of endpoints is given in the table below. Table was compiled by RMS from 10 individual tables from the report. T-test was performed on cumulative mortality (%). In the table significant effects were marked for the corresponding corrected cumulative mortality.

Table B.9.4.1.3-04 Mean consumption of feeding solution, mean intake of test item, mean intake accumulated over test days and cumulative mortality in the BYI 02960-DFEAF treatment groups and the control group (day 1-10). A negative sign indicates a decrease as compared to the control.

			Test item (µg as/L) [1]
day	**Treatment level**	**control**	**10000**
1	Mean consumption of feeding solution (mg/bee) *Corr. cum. mortality (%) (control mortality 0.0%)*	59	59 *0.00*
2	Mean consumption of feeding solution (mg/bee) *Corr. cum. mortality (%) (control mortality 0.0%)*	57	60 *0.00*
3	Mean consumption of feeding solution (mg/bee) *Corr. cum. mortality (%) (control mortality 0.0%)*	60	59 *0.00*
4	Mean consumption of feeding solution (mg/bee) *Corr. cum. mortality (%) (control mortality 0.33%)*	61	66 *-0.33*
5	Mean consumption of feeding solution (mg/bee) *Corr. cum. mortality (%) (control mortality 1.0%)*	43	47 *-1.01*
6	Mean consumption of feeding solution (mg/bee) *Corr. cum. mortality (%) (control mortality 1.33%)*	53	53 -1.35
7	Mean consumption of feeding solution (mg/bee) *Corr. cum. mortality (%) (control mortality 1.67%)*	39	36 -1.70
8	Mean consumption of feeding solution (mg/bee) *Corr. cum. mortality (%) (control mortality 1.67%)*	49	48 -1.70
9	Mean consumption of feeding solution (mg/bee) *Corr. cum. mortality (%) (control mortality 2.00%)*	49	42 ** -2.04
10	Mean consumption of feeding solution (mg/bee) *Corr. cum. mortality (%) (control mortality 3.67%)*	45	46 -3.81 [3]

	Overall mean consumption of sucrose solution [mg/bee/d] [2]	**51.4**	**51.5**
	Mean intake accumulated over 10 test days [µg as/bee]	**-**	**4.348**

1. The control group was fed with untreated 50 % (w/v) sucrose solution mixed with 1 % acetone; all test item treatment groups were fed with BYI 02960 treated 50 % (w/v) sucrose solution mixed with 1 % acetone
2. The mean values per cage over the test period were used as basis for the calculation of the mean consumption of feeding solution per treatment over the test period [mg/bee] Density of the sucrose solution was in the range of 1.180-1.189 g/cm3.
3. Determined to be the NOEC (not significantly different compared to the control; Fisher's Exact Test (Bonferroni-Holms corrected, one-sided, p≤ 0.05))

* Food consumption significantly lower compared to the control group (t-test; one-sided, p<0.05)

After 10 days of continuous exposure, mortality in the test item treatment group was not significantly different compared to the control group. The cumulative control mortality accounted to 3.67 %, as determined at the final assessment (day 10). In the test item treatment group at 10000 µg as/L, the cumulative mortality at the final assessment (day 10) accounted to 0.00 % (corrected -3.81 %).

Furthermore, neither sublethal effects nor behavioural abnormalities were observed throughout the entire testing period in the test item treatment group. The test item treatment level of 10000 µg as/L was determined to be the NOEC, Fisher's Exact Test (Bonferroni-Holms corrected, one-sided, p ≤ 0.05).

The overall mean daily consumption of the aqueous sucrose feeding solution (i.e. the average value over 10 days) in the test item treatment group was virtually identical to the untreated control group (51.5 mg/bee in the test item treatment compared to 51.4 mg/bee in the control group).

The mean daily consumption of the aqueous sucrose feeding solution was statistically significantly reduced in the test item treatment group (42 mg/bee) compared to the control group (49 mg/bee) only on day 9, (t-test; one-sided, p ≤ 0.05). On all other test days, the mean daily consumption of the aqueous sucrose feeding solution was almost identical in the test item treatment group compared to the control group (day-by-day comparison).

The accumulated nominal intake of the test item BYI 02960-DFEAF via BYI 02960-DFEAF - treated aqueous sucrose feeding solution was 4.35 µg as/bee after 10 days of continuous exposure.

Remarks by RMS

A toxic standard was not included in this test, since a toxic reference substance had not been defined or validated for this type of study. The NOEC was determined to be ≥ 10000 µg as/L at the end of the test period. The result can be used for risk assessment.

Description

The chronic effects of the test item BYI 02960-hydroxy, a metabolite of flupyradifurone, on the honey bee, *Apis mellifera* L., were assessed in a 10 days continuous feeding test in the laboratory. The test was carried out with young adult worker bees derived from a healthy colony. The bees were brushed off the brood combs of one colony in order to receive young, viable adult worker bees (e.g. nurse bees). The bees were collected and distributed into the test cages one day before start of the test and were kept under test conditions over night. Bees that died during this acclimatisation period were replaced by reserve bees that were collected at the same time. During the entire test period, the bees were kept in cages made of stainless steel (base: 8.2 cm x 4 cm; height: 6 cm). The front side of the cages was equipped with a transparent pane so that the bees could be observed. The bottom of the cages consisted of a perforated board, which guaranteed sufficient air supply for the test animals. The test cages were lined with filter paper. The feeding solutions were offered to the bees in syringes fitted into the test cages.

Ten replicates of 10 honey bees each were tested (in total 100 honey bees per test item concentration). The control group comprised 30 replicates of 10 honey bees each (in total 300 honey bees). A toxic standard was not included.

Samples of the stock solution and all feeding solutions were taken directly after preparation for subsequent residue analysis. Samples were analysed by reversed-phase HPLC with Turbolon spray MS/MS-detection.

The number of dead bees in the individual test cages was recorded every day at about the same time of day during the 10 days test period. Abnormal behavioural effects and behavioural differences were assessed.

Test conditions: 25.1 – 25.8°C, 51.2 – 69.4% RH, 24 h darkness, except during observations.

The mortality of the test item treatments was corrected for control mortality, according to ABBOTT (1925), modified by SCHNEIDER-ORELLI (1947).

The consumption of feeding solution per bee/day was calculated by dividing the total daily consumption per cage by the mean number of living bees at the corresponding time interval. The mean value per treatment group as well as the daily mean food consumption per bee was calculated.

The NOEC was determined by using Fisher's Exact Test (Bonferroni-Holms corrected, one-sided, $p \leq 0.05$). Data of food consumption were analysed by using the t-Test (with Bonferroni-Holms correction, one-sided, $p \leq 0.05$). Statistical calculations were made by using the statistical program SAS release Version 9.2.

Results

The actual concentration of BYI 02960-hydroxy in the feeding solutions, determined for each preparation day, was in the range from 92 to 103% of the nominal concentration (mean 99%).

A summary of endpoints is given in the table below. Table was compiled by RMS from 10 individual tables from the report. T-test was performed on cumulative mortality (%). In the table significant effects were marked for the corresponding corrected cumulative mortality.

Table 9.4.1.3-05. Mean consumption of feeding solution, mean intake of test item, mean intake accumulated over test days and cumulative mortality in the BYI 02960-hydroxy treatment groups and the control group. A negative sign indicates a decrease as compared to the control.

			Test item (µg as/L) [1]
day	**Treatment level**	**control**	**10000**
1	Mean consumption of feeding solution (mg/bee) *Corr. cum. mortality (%) (control mortality 0.0%)*	59	59 *0.00*
2	Mean consumption of feeding solution (mg/bee) *Corr. cum. mortality (%) (control mortality 0.0%)*	57	60 *0.00*
3	Mean consumption of feeding solution (mg/bee) *Corr. cum. mortality (%) (control mortality 0.0%)*	60	59 *0.00*
4	Mean consumption of feeding solution (mg/bee) *Corr. cum. mortality (%) (control mortality 0.33%)*	61	63 *0.67*
5	Mean consumption of feeding solution (mg/bee) *Corr. cum. mortality (%) (control mortality 1.0%)*	43	40 *0.01*
6	Mean consumption of feeding solution (mg/bee) *Corr. cum. mortality (%) (control mortality 1.33%)*	53	52 -0.32
7	Mean consumption of feeding solution (mg/bee) *Corr. cum. mortality (%) (control mortality 1.67%)*	39	37 -0.67
8	Mean consumption of feeding solution (mg/bee) *Corr. cum. mortality (%) (control mortality 1.67%)*	49	46 0.36
9	Mean consumption of feeding solution (mg/bee) *Corr. cum. mortality (%) (control mortality 2.0%)*	49	43 1.05
10	Mean consumption of feeding solution (mg/bee) *Corr. cum. mortality (%) (control mortality 3.67%)*	45	39 -0.66 [3]
	Overall mean consumption of sucrose solution [mg/bee/d] [2]	**51.4**	**49.6**
	Mean intake accumulated over 10 test days [µg as/bee]	**-**	**4.198**

1. The control group was fed with untreated 50 % (w/v) sucrose solution mixed with 1 % acetone; all test item treatment groups were fed with BYI 02960 treated 50 % (w/v) sucrose solution mixed with 1 % acetone
2. The mean values per cage over the test period were used as basis for the calculation of the mean consumption of feeding solution per treatment over the test period [mg/bee]. Density of the sucrose solution was in the range of 1.180-1.189 g/cm3.
3. Determined to be the NOEC (not significantly different compared to the control; Fisher's Exact Test (Bonferroni-Holms corrected, one-sided, p≤ 0.05)).

After 10 days of continuous exposure, mortality in the test item treatment group was not significantly different compared to the control group. The cumulative control mortality accounted to 3.67 %, as determined at the final assessment (day 10). In the test item treatment group at 10000 µg as/L, the cumulative mortality at the final assessment (day 10) accounted to 3.03 % (corrected -0.66 %).

Furthermore, neither sublethal effects nor behavioural abnormalities were observed throughout the entire testing period in the test item treatment group. The test item treatment level of 10000 µg as/L was determined to be the NOEC (Fisher's Exact Test (Bonferroni-Holms corrected, one-sided, p ≤ 0.05)).

The overall mean daily consumption of the aqueous sucrose feeding solution (i.e. the average value over 10 days) in the test item treatment group was almost identical to the untreated control group (49.6 mg/bee in the test item treatment compared to 51.4 mg/bee in the control group).

The mean daily consumption of the aqueous sucrose feeding solution was not significantly different between the control group and the test item treatment group throughout the entire testing period (day-by-day comparison).

The accumulated nominal intake of the test item via BYI 02960-hydroxy - treated aqueous sucrose feeding solution was 4.20 µg as/bee after 10 days of continuous exposure.

Remarks by RMS

A toxic standard was not included in this test, since a toxic reference substance had not been defined or validated for this type of study. The NOEC was determined to be ≥ 10000 µg as/L at the end of the test period. The result can be used for risk assessment.

1. The control group was fed with untreated 50 % (w/v) sucrose solution mixed with 1 % acetone; all test item treatment groups were fed with BYI 02960 treated 50 % (w/v) sucrose solution mixed with 1 % acetone
2. The mean values per cage over the test period were used as basis for the calculation of the mean consumption of feeding solution per treatment over the test period [mg/bee]. Density of the sucrose solution was in the range of 1.185-1.193 g/cm3.

3. Determined to be the NOEC (not significantly different compared to the control; Fisher's Exact Test (Bonferroni-Holms corrected, one-sided, p≤ 0.05)).

* Food consumption significantly lower compared to the control group (t- test pooled; one-sided, p □ 0.05)

After 10 days of continuous exposure, mortality in the test item treatment group was not significantly different compared to the control group. The cumulative control mortality accounted to 2.33 %, as determined at the final assessment (day 10). In the test item treatment group at 10000 µg as/L, the cumulative mortality at the final assessment (day 10) accounted to 5.00 % (corrected 2.73 %). Furthermore, neither sublethal effects nor behavioural abnormalities were observed throughout the entire testing period in the test item treatment group. The test item treatment level of 10000 µg as/L was determined to be the NOE, Fisher's Exact Test (Bonferroni-Holms corrected, one-sided, p ≤ 0.05)).

The overall mean daily consumption of the aqueous sucrose feeding solution (i.e. the average value over 10 days) in the test item treatment group was comparable to the untreated control group (49.1 mg/bee in the test item treatment compared to 46.2 mg/bee in the control group).

The mean daily consumption of the aqueous sucrose feeding solution was statistically significantly reduced in the test item treatment group (46 mg/bee) compared to the control group (55 mg/bee) only on day 1 (t- test pooled; one-sided, p ≤ 0.05). On all other test days, the mean daily consumption of the aqueous sucrose feeding solution was almost identical or even higher in the test item treatment group compared to the control group (day-by-day comparison).

The accumulated nominal intake of the test item 6-chloropicolyl alcohol via 6-chloropicolyl alcohol - treated aqueous sucrose solution was 4.13 µg as/bee after 10 days of continuous exposure. The accumulated nominal intake of the test item 6-chloropicolyl alcohol via 6-chloropicolyl alcohol - treated aqueous sucrose solution was 4.18 µg as/bee after 10 days of continuous exposure.

Remarks by RMS

A toxic standard was not included in this test, since a toxic reference substance had not been defined or validated for this type of study. The NOEC was determined to be ≥ 10000 µg as/L at the end of the test period. The result can be used for risk assessment.

B.9.4.1.3.1 Chronic toxicity on honeybee larvae

Study KIIA 8.16.1/07 (also submitted as Study KIIIA 10.4.6.1/01)

		(January, 2008) and the recommendations of the honeybee larvae laboratory ring-test group, organized by ICPBR (AUPINEL ET AL., 2009)			
test substance	:	BYI 02960, Batch no. BYI 02960-01-03	acceptability	:	Acceptable
a.s. content	:	96.2%	NOEC	:	≥ 10000 µg as/diet

Description

First instar larvae of *Apis mellifera carnica* were collected preferably from a single bee colony (test runs No. 3, 4 and 5). Due to an insufficient number of healthy bee larvae on day +1, the use of two colonies was necessary for test run No. 1 and 2. Larvae originating from each colony were distributed equally to each test plate. The colonies were obtained from a local bee keeper, in Wermelskirchen, North-Rhine Westphalia, Germany, and were free of obvious symptoms of bee diseases and were located close to the laboratory in Monheim am Rhein, North-Rhine Westphalia, Germany. To obtain first instar larvae, the queen of the selected colony was confined on day -3 in her colony in a queen excluder cage, containing a comb with empty cells, for approximately 24 hours. The excluder cage was placed into the centre of the hive, so that the queen and the larvae were well-tended by nurse bees. On day -2, about 24 hours after encaging, the queen was removed from the cage after checking the presence of freshly laid eggs. The comb containing the eggs was kept inside the cage during the incubation stage and until grafting of the larvae on day +1. At day +1, the comb, containing small first instar larvae, was carried from the bee hive to the laboratory of the test facility for grafting of the larvae into the testing units. For the transport of the comb, a wooden container was used in order to keep the ambient temperature for the bee larvae as stable as possible.The bee larvae were fed with standardised amounts of untreated artificial diet at day +1 and day +3. On day +4, +5 and +6, the bee larvae in the test item treatment groups were fed with standardised amounts of test item spiked artificial exposure diet. On day +4, the bee larvae in the reference item treatment group were fed with standardised amounts of reference item spiked artificial exposure diet. Concurrently, the bee larvae in the control group (on day +4, +5 and +6) and in the reference group (on day +5 and +6) received untreated artificial exposure diet, respectively.

Larvae were maintained during the test in 48-well culture plates with commercially obtained grafting cells of an internal diameter of 9 mm. Before using the grafting cells for inoculating bee larvae, the cells were disinfected. After the disinfection one grafting cell was placed into each well of a 48-well culture plate, respectively, which was previously half-filled with a piece of a dental roll (cellulose), wetted with a solution of 15.5% glycerol in 0.4% MBC solution. The grafting cells were inserted on top of these dental rolls. These so prepared 48-well culture plates were thereafter closed with a lid and stored at approximately +5°C in a refrigerator until use. During the biological phase of the test, no lid was used on the 48-well culture plates.

Applications

The test item BYI 02960 (tech.) was incorporated into the artificial exposure diet at the following nominal test concentrations: 150, 600, 2500 and 10000 µg as/kg diet. Dimethoate (tech.) was used as

toxic reference at a nominal test concentration of 3.0 µg as/L. Emerging bees were fed with untreated syrup and pollen powder ad libitum.

Observations

On day +22, the number of hatched adult bees was determined. Mortality was determined on day +5, +6, +7, +8, +11, +13, +15 and +22. Dead test animals were discarded for sanitary reasons.

Analysis concentrations in diet

The actual concentration of BYI 02960 in the test item spiked exposure diet was determined according to analytical method 01206 (MR-10/046, 2010-07-12, R. Schöning, P. Köster), by using High Performance Liquid Chromatography, coupled with tandem mass spectrometry.

Calculations and statistics

Mortalities are expressed in percentage and in a corrected percentage according to Abbott (ABBOTT, 1925).

The data of the test item treatment groups were statistically evaluated and compared to the control data by using a Chi^2 Test.

Results

Climatic conditions.

During the development of the honeybee larvae, the larvae were incubated at about +35°C. From day +1 to +8, the relative humidity inside the incubator was on average about 95 ± 5% and from day +8 to +22 the mean relative humidity was about 80 ± 5%.

Actual concentrations

Actual concentrations ranged from 87 to 118% of nominal.

Validity criteria

In total, five independent test runs were conducted. In all test runs, the validity criteria as stated in the INRA - method for testing pesticide toxicity to honeybee brood in laboratory conditions (January 2008) and proposed by the recommendations of the honeybee larvae laboratory ring-test group (AUPINEL et al., 2009) were met (i.e. mortality in the control group ≤ 15% and in the reference group ≥ 50% until day +7). In addition to the validity criteria as proposed by the ring-test group, an additional self-set validity criterion was employed (i.e. mortality in the control group ≤ 30% until day +22). This self-set validity criterion was applied in order to exclude test runs from which it is difficult to derive biologically meaningful information due to elevated mortality levels.

Results

Results of the five runs are reported in the following table (copied from the report).

Table 9.4.1.3-09 Control and test item performance and statistical evaluation

Test object	Honeybee larvae *(Apis mellifera carnica)*					
	Control (untreated exposure diet)	Test item (BYI 02960 - spiked exposure diet)				Reference item (dimethoate - spiked exposure diet)
Test concentration (µg a.s./kg diet)	---	150	600	2500	10000	3.0 (µg a.s./larva)

LOEC [b]	>10000 µg a.s./kg diet					---

[a] Although control performance met the validity criteria as stated in the INRA - method for testing pesticide toxicity to honeybee brood in laboratory conditions (January 2008), the self-set validity criterion for control performance at the end of the test (i.e. ≤ 30%) was not met; no distinct differences in larval mortality can be observed at concentrations of up to and including 10000 µg BYI 02960 a.s./kg diet (as the self-set validity criterion was not met, no detailed statistical evaluation is presented; however, when subjecting the data to statistical analysis, there is no statistical significance up to and including 10000 µg a.s./kg diet; Chi^2 Test [Bonferroni-Holms corrected, one-sided, α = 0.05])

[b] Chi^2 Test, (Bonferroni-Holms corrected, one-sided, α = 0.05)
n.s.: mean value not statistically significantly different compared to the control

Overall, three test runs (2, 4 and 5) fulfilled both the validity criteria as proposed by the INRA-method (January, 2008) for testing pesticide toxicity to honeybee brood in laboratory conditions and the self-set validity-criterion of ≤ 30% mortality in the control group until day +22. The statistical processing of the data as obtained in the test runs 2, 4 and 5 consistently revealed no statistically significant effects on mortality of exposed honeybee larvae until day +22 (end of the test, emergence) at concentrations of up to and including 10000 µg BYI 02960 as/kg diet (Chi2 Test, Bonferroni-Holms corrected, one-sided, α = 0.05). This conclusion is supported by the findings of the test runs 1 and 3.

Remarks by RMS

Validity criteria as stated in the INRA – method (control mortality ≤ 15%, reference mortality ≥ 50% until day +7) were met for all five test runs. Larvae from test runs 3, 4 and 5 were collected from the same single bee colony. The larvae from test runs 1 and 2 were collected from another colony. The five runs can therefore not be regarded as true replicas (from the same colony). However, since this study was performed, the OECD has published a guidance document on acute larval tests (OECD 237) and a draft guidance document on repeated exposure larval tests (latest version 25th Nov 2013) and in both, larvae of three colonies are used. Since the results of the positive control show clear effects and the test concentrations show no effect, the NOEC as determined in this in-vitro honeybee larvae study of ≥ 10000 µg BYI 02960 as/kg diet (fed on days 4, 5 and 6 of the larval stage) can be used for risk assessment.

From Table 5 of the study report, which contains the nominal feeding rates of the larvae in µg a.s./larvae, it can be calculated that the NOEC level of 10.000 µg a.s./kg diet corresponds to an accumulated (from exposure on day +4, +5 and +6 after grafting of the larvae) test item intake of 1.32 µg a.s./larvae (nominal).

B.9.4.1.4 Foliage residue toxicity in the laboratory (no EU data requirement)

There are currently no harmonised and ring tested test guidelines in Europe to assess the residual foliage toxicity to honey bees. Nonetheless, in North America, there are test guidelines available investigating the toxicity of foliar residues on honey bees under laboratory conditions. To meet USA requirements, the applicant has performed this study. As BYI 02960 is applied to the foliage via spray, the SL 200 straight formulation was selected for this study. RMS did not evaluate the study since it is not an EU data requirement and it is unclear how it can be used in the risk assessment. The endpoint as determined by the notifier is shown in Table B.9.4.1.4-01.

Table B.9.4.1.4-01 Chronic toxicity of BYI 02960 honey bee larvae in the laboratory

Test substance	Ecotoxicological Endpoint: NOEC / NOED	Reference	Remark

BYI 02960 SL 200	No treatment-related adverse effects on behaviour and on survival of honey bees were observed when the bees were exposed for 24 hours to alfalfa foliage, collected after 3, 8 and 24 hours after treatment with BYI 02960 200 SL at a rate corresponding to 205 g a.i./ha.	Porch & Krueger 2011 KIIIA1 10.4.3/01	Study not evaluated by RMS. PMRA Canada deems this study 'reliable with restrictions' [1.]

[1] The following deviations from the test guideline were indicated in PMRA-Canada's summary of 2013/04/26 (text copied from the reporting table of the OECD Joint Review of flupyradifurone, containing comments from US-EPA and Australia):

- Test plots used are not considered to be sufficiently large.
- A formulation blank (plot) was not used, only water control and treatment plots.
- Foliage was coarsely chopped and mixed by hand prior to transferring to the laboratory for analysis. It is not known whether chopping prior to transport to the lab had an effect on residues and if so, to what extent.
- Despite collection of samples for residue analysis, residue analysis was not performed, only nominal application rates were provided.

The validity/acceptance criteria were met. The study is considered reliable with restrictions.

B.9.4.2 Semi-field studies (IIIA 10.4.7)

Study KIIIA 10.4.7/01

Characteristics

Reference	:	Schnorbach, H. (2012a)	nominal dose		0.75 and 1.5 L/ha = 75 and 150 g a.s./ha
type of study	:	Honeybee semi-field tunnel test	species	:	Honey bee (*Apis mellifera*)
year of execution	:	2008	observation duration	:	29 d
GLP statement	:	No	exposure duration	:	7 d
Guideline	:	OEPP/EPPO guideline No. 170 (3), 2001	dosing method	:	Tunnel test in flowering *Phacelia tanacetifolia*, 1x foliar spray during flowering and active foraging of bees
test substance	:	BYI 02960 SL 100, Batch no. 2008-000707	acceptability	:	Less reliable due to non-GLP
a.s. content	:	100 g flupyradifurone 100 g/L (analysed)	Result	:	No adverse effect on mortality, flight intensity, brood development; Effects on behaviour not reported

Description

The study was conducted on test fields that were located within the local subdistrict “Billiger Wald”, close to 53881 Euskirchen-Billig, North-Rhine Westphalia, Germany.

The overall size of the test field was approximately 1000 m² (100 m x 10 m). The crop *Phacelia tanacetifolia* was drilled on 21 April 2008 by using a sowing machine. The *Phacelia*-seeds were not seed-treated and the crop has not received any maintenance treatment with plant protection products.

Three replicates (= three gauze tunnels) were set up for each experimental group, consisting of an untreated control, a toxic reference (Insegar with a.s. fenoxycarb, 0.6 kg product/ha, corresponding to 150 g as/ha) and two concentrations of the test item (75 g as/ha, 150 g as/ha), respectively. In addition, two replicates (=two gauze tunnels) were set up for an extra toxic reference Actara (thiamethoxam 25% w/w), application rate 0.2 kg product/ha, corresponding to 50 g thiamethoxam as/ha. The tunnels were covered with gauze, preventing the bees from escaping but allowing for sufficient ventilation (mesh-size approx. 1.5 mm). The floor space of each tunnel was approximately 50 m^2 (5 m width x 10 m length). The distance between the tunnels was approx. 3 - 5 m.

Honey bees of the race *Apis mellifera carnica* L. were obtained from a beekeeper.

On 16 June 2008, one nucleus was prepared by taking 30 brood combs (size: 370 mm x 223 mm) from different bee colonies plus 10 food combs and honey bees, and placed into a multiple-storey hive with 4 supers. One queen was added.

On 20 June 2008, a sufficient quantity of 3-comb-hives were prepared by combining two brood combs from the nucleus (plus honey bees) with one empty frame, respectively. Finally, one queen was placed into each 3-comb-hive, containing approx. 2500 honey bees. All queens of the employed experimental colonies (3-comb-hives, prepared as outlined above) used in this test were sisters. The assignment of the bee colonies to the tunnels (test units) followed a randomized complete block design.

The honey bees were placed inside the tunnels after the beginning of flowering on 22 June 2008, 4 days before the respective application (DAA-4), in the morning. During the applications, honey bees

were actively foraging on the crop but care was taken not to directly overspray the colonies. In front of the bee hives, dead bee traps and linen sheets (1 m x 1 m) were installed. In addition, at the tunnel edges, linen sheets of 40 - 50 cm width x 30 m total length (2 x 10 m (left and right tunnel length, respectively) + 2 x 5 m (tunnel width at tunnel ends, respectively)) were spread out on the ground

Observations

The small honey bee colonies in all experimental groups were examined daily during the confined exposure period for effects on mortality, behaviour and foraging activity (10 days in succession, from DAA-3 until DAA6) and hive weight. Honey bee colonies were relocated to a monitoring site on DAA8, where the bees were allowed to forage freely. Colony assessments, including an assessment of colony strength, eggs, larvae, pupae, nectar- and pollen stores as well as hive weight, were performed in regular intervals during and after the confined exposure period until DAA27 (last colony assessment).

The following parameters were expressed as percentage values per comb area on the study days DAA-1, DAA4, and DAA6 (during confinement) as well as on the study days DAA 14, DAA 21 and on DAA 27 (on the monitoring site).

- Nectar stores: The amount of sampled nectar was assessed by the estimation of the percentage of total comb area, on both sides of the comb, containing cells filled with nectar. The nectar storage was compared between control, test item and toxic references.
- Pollen stores: The amount of sampled pollen was assessed by the estimation of the percentage of total comb area, on both sides of the comb, containing cells with pollen. The pollen storage was compared between control, test item and toxic references.
- Egg-laying activity: The egg-laying activity of the queens was assessed by inspection of the brood combs. During each inspection, the percentage of total comb area was estimated on both sides of the comb, containing cells with eggs. The egg deposition was compared between control, test item and toxic references.
- Breeding success: During each inspection, the percentage of total comb area was estimated on both sides of the comb, containing honey bee larvae and pupae (capped brood). Abundance of larvae and pupae (capped brood) was compared between control, test item and toxic references.
- Colony strength: During each inspection, the percentage of total comb area was estimated on both sides of the comb, which was covered by adult honey bees. This endpoint integrates potential impacts of the test item on breeding success, longevity and mortality of honey bees. Abundance of adult honey bees found on the combs was compared between control, test item and toxic references. A proportion of the adult bees of the hives could have been foraging at the moments of the assessment, but as the assessment of all experimental groups was conducted within a short period of time, it is assumed that this proportion is equal for all hives.

Any behavioural anomalies, including e.g. exaggerated motility, aggressiveness, discoordinated movements (trembling, flight incapability, etc.), apathy, lethargic behaviour, clustering at the hive

entrance, clustering on the gauze netting of the tunnel, obvious symptoms of intoxication (cramping, agony, etc.), etc., whenever observed, were recorded with the date and daytime of observation. Temperature and relative humidity was recorded during the confinement of the honey bees in the tunnels using a calibrated data logger inside one control tunnel from 24 June 2008 (DAA-2) until 4 July 2008 (DAA8), while rainfall was measured outside the control tunnel by means of a portable rain-gauge.

Results

Climatic conditions

Measured minimum temperatures ranged between 8.8 and 16.7°C and maximum temperatures between 20.2 and 46.0°C, the minimum relative humidity (RH) ranged between 0.3 and 35.6% and the maximum RH between 86.7 and 100.5%.

Mortality and foraging activity

Results on foraging activity and mortality are reported in the following table (copied from the report).

Table 9.4.2-1. Mortality and foraging activity after application.

Time Interval	Untreated	Insegar	BYI 02960 (75 g a.s./ha)	BYI 02960 (150 g a.s./ha)	Actara
Foraging activity (Daily average number of flower visits on 1 m² per experimental group)					
	three replicates				two replicates
DAA-3 – DAA-1	29.4	28.7	29.6	29.2	28.7
DAA0ba	24.3	26.2	25.5	28.3	26.5
DAA0aa	40.2	40.8	39.6	37.2	0.4
DAA1	22.8	23.3	22.4	22.8	0.3
DAA2 – DAA3	39.3	35.5	36.8	37.5	0.3
DAA4 – DAA6	39.1	38.1	37.8	37.3	6.7
Mortality (Daily average number of dead worker bees, drones and pupae in front of the hive per experimental group)					
	three replicates				two replicates
Worker bees, DAA-3 – DAA-1	1.4	2.1	0.7	1.3	1.3
Worker bees, DAA0ba	1.7	2.0	1.7	2.3	0.5
Worker bees, DAA0aa	1.3	0.0	0.7	1.7	465.5
Worker bees, DAA1	0.0	1.3	0.0	0.0	153.0
Worker bees, DAA2 – DAA3	0.3	0.3	0.3	0.0	139.8
Worker bees, DAA4 – DAA6	1.9	2.1	2.8	1.4	301.3
Worker bees, DAA7 – DAA11	0.0	0.2	0.0	0.3	3.3
Worker bees, DAA12 – DAA25	0.1	0.3	0.5	0.4	0.4
Drones, DAA-3 – DAA0ba	0.0	0.0	0.0	0.0	0.0
Drones, DAA0aa – DAA25	0.0	0.0	0.0	0.0	0.0
Pupae, DAA-3 – DAA-1	0.1	0.0	0.0	0.0	0.0
Pupae, DAA0ba	0.0	0.0	0.0	0.0	0.0
Pupae, DAA0aa	0.0	0.0	0.0	0.0	0.0
Pupae, DAA1	0.0	0.0	0.0	0.0	0.0
Pupae, DAA2 – DAA3	0.3	0.0	0.2	0.0	0.0
Pupae, DAA4 – DAA6	0.0	0.0	0.0	0.0	0.2
Pupae, DAA7 – DAA11	0.0	1.8	0.1	0.0	0.0
Pupae, DAA12 – DAA25	0.0	3.2	0.0	0.0	0.1

DAA = Day after application; DAA0ba = Day of application, before application; DAA0aa = Day of application, after application; a.s. = active substance

Foraging activity after application was comparable in the control group, in the test item group (as BYI 02960, at 75 g as/ha and 150 g as/ha, respectively) as well as in the Insegar (as fenoxycarb) group, while foraging activity decreased strongly to very low levels in the Actara (as thiamethoxam) group. Foraging activity in the Actara (as thiamethoxam) group has not recovered during the entire confinement period. In the test item group at 150 g as/ha, foraging activity was slightly reduced immediately after the treatment when compared to control, but recovered fully within a couple of hours after treatment and followed the control group at any point in time thereafter.
While worker bee mortality after application was comparably low in the control-, in the test item (as BYI 02960 75 g as/ha and 150 g as/ha)- and in the Insegar (as fenoxycarb) group at any point in time during the study, worker bee mortality was strongly increased in the Actara (as thiamethoxam) group. Mortality of worker bees in the Actara (as thiamethoxam) group remained on an elevated level compared to control at least until the end of the confinement period (DAA6).
In none of the experimental groups there was any conspicuous drone mortality.
Except for the Insegar group (as fenoxycarb), where the number of dead pupae was considerably increased from DAA11 until at least DAA14 (potentially from about DAA7 until DAA18), only some single dead pupae were found in any of the other experimental groups. In the Actara (as thiamethoxam) group, the treatment resulted at least in transient effects on hive weight development, the extent of nectar- and pollen stores, on larval- and pupal abundance as well as on population development. In the Insegar (as fenoxycarb) group, the treatment resulted at least in transient effects on larval- and pupal abundance as well as on population development.

Weight development of the bee hives

Results for weight development are reported in the following figure (copied from the report).

Figure 9.4.2-1. Weight development of the bee hives (average value per experimental group).

During confinement, the hive weights in all experimental groups decreased due to the tunnel-specific limited foraging conditions. After the end of the confined exposure period (DAA8), hive weight in all experimental groups was very similar and mirrored the relative proportions as before the treatment, except for the Actara group, where hive weights had decreased in a more pronounced manner. At the first assessment after confinement (DAA14), hive weights in all experimental groups had further decreased proportionally and reached their overall minimum, with the Actara group not having recovered when compared to control. Thereafter, at the following assessment days, hive weights had increased with no distinct differences between the different experimental groups, but with the typical fluctuations for this variable endpoint under field conditions, once the bees were allowed to forage freely after confinement; the hive weights at the last assessment day (DAA27) had still not recovered in the Actara group when compared to control. No adverse effects of the test item were found on the hive weight development.

Number of honey bees on the tent wall

The average number of honey bees at the tent walls shortly before the actual treatment (DAA0ba) was low and comparable in all experimental groups. Immediately after the treatment (DAA0aa), the average number of honey bees at the tent walls increased in all experimental groups, but more pronounced in the test item group at 150 g as/ha and in the Actara group, respectively. At the day following the treatment (DAA1), the average number of honey bees at the tent walls was in all experimental groups again low, comparable and even below the corresponding level shortly before the respective treatment (DAA0ba). Thereafter, until the end of the confinement period, the average number of honey bees at the tent walls remained on a comparable level in all experimental groups, showing the typical fluctuations of this parameter. No adverse effects of the test item were found.

Nectar stores

The total average comb area with cells containing nectar in % of the total comb area per experimental group, over time is reported in the following figure (copied from the report).

Figure 9.4.2-2. Nectar stores in % of the total comb area per experimental group (total average)

No adverse effects of the test item were found on nectar storage.

Pollen stores

The quantity of pollen stores found in the combs was recorded at regular intervals throughout the study period, starting on the day before application. The data are summarised in the following figure (copied from the report).

Figure 9.4.2-3. Pollen stores in % of the total comb area per experimental group (total average)

No adverse effects of the test item were found on pollen storage.

Population development and breeding performance

Egg-laying activity was assessed and recorded at regular intervals throughout the study

period, starting on the day before application. The data are presented in the following figure (copied from the report).

Figure 9.4.2-4. Comb area with cells containing eggs in % of the total comb area per experimental group (total average)

No adverse effects of the test item were found on egg-laying activity.

<u>Abundance of honey bee larvae</u>

Abundance of honey bee larvae was assessed and recorded at regular intervals throughout the study period, starting on the day before application. The data are presented in the following figure (copied from the report).

Figure 9.4.2-5. Comb area with cells containing larvae in % of the total comb area per experimental group (total average)

No adverse effects of the test item were found on honey bee larvae.

Abundance of honey bee pupae

Abundance of honey bee pupae (capped brood) was assessed and recorded at regular intervals throughout the study period, starting on the day before application. The data are presented in the following figure (copied from the report).

Figure 9.4.2-6. Comb area with cells containing pupae in % of the total comb area per experimental group (total average)

No adverse effects of the test item were found on honey bee pupae.

Total abundance of honey bee brood

The total abundance of honey bee brood was assessed and recorded at regular intervals throughout the study period, starting on the day before application. The data are presented in the following figure (copied from the report).

Figure 9.4.2-7. Comb area with cells containing brood in % of the total comb area per experimental group (total average)

No adverse effects of the test item were found on total brood abundance.

Population development

The size of the comb area covered with adult honey bees was assessed at regular intervals throughout the study period, starting on the day before application. The data are presented in the following figure (copied from the report).

Figure 9.4.2-8. Comb area covered with adult honey bees in % of the total comb area per experimental group (total average)

No adverse effects of the test item were found on population development.

Conclusions of the author

The results of the study revealed that BYI 02960 can be applied via foliar application at a rate corresponding to 75 g as/ha and 150 g as/ha, respectively, into a full-flowering and highly bee attractive crop, as represented here by *Phacelia tanacetifolia*, during honey bees actively foraging on the crop, without adverse effects on mortality, foraging activity, behaviour, brood-, food-, and population development as well as on overall hive vitality.

Remarks by RMS

A positive control was included in the test and showed that the test system was behaving as expected. Author concluded that behaviour was not affected. This could not be evaluated by RMS as observations on behaviour were not reported.

According to the EFSA Opinion on the Science behind the development of a risk assessment of plant protection products for bees (EFSA Journal 2012, 10: 2668, section 3.5.1), the main exposure route for bee brood is via pollen. Since *Phacelia tanacetifolia* is a major source of pollen, and pollen from uncontaminated sources was not present in the tunnels, the present test is suitable to show potential effect of flupyradifurone on brood related parameters, mortality and flight intensity.

The results of the study show that there is no risk to honeybees by foraging on *Phacelia tanacetifolia* sprayed once with BYI 02960 (at both application rates; 75 and 150 g as/ha) in a tunnel test. There were no test item related effects in any endpoint (except for behaviour as these data were not reported). This study can be considered for risk assessment for BYI 02960 but should be considered with caution as the study was not performed under GLP.

Expert discussion in Pesticide Peer Review meeting 124 (December 2014):

The discussion on this first study by Schnorbach 2012a includes general discussions on the design and usefulness of semi-field studies.

(Please note that the word ‘effect’ in the text below might be interpreted as different from the control (i.e. may or may not include effects from the treatment), pending on the context.)

The weight development of the bee hives in the treated groups was slightly lower at later sampling points. Similar picture in egg laying.

Some experts considered that these studies were mostly well performed and useful (except for the non-GLP status). The size of frames were relatively small and the colonies were quite small <3000 bees (noting that the EFSA GD recommends >6000 bees). When young bees are primarily used, the biological variability can be large. The adaption of young bees may be an additional issue, there was 6 days between when the queen was added and the test substance was applied. This resulted in many stressful steps for the colony just prior to application.

The conditions of a semi-field study are very artificial limiting their usefulness when comparing to the field i.e. the colony results are of limited use as there is not sufficient food so a downward trend will always be observed – limiting the ability of the study to detect treatment related effects on the colony. The large advantage is to ensure that there is no alternative foraging area other than the treated crop. The assessment methodology of the comb was discussed and the experts agreed that taking a digital image of the comb is less stressful for the bees and therefore is an advantage over making an assessment by eye.

Overall, the experts agreed with the RMS's assessment of this study.

Study KIIIA 10.4.7/02

Characteristics

Reference	:	Schnorbach, H. (2012b)	nominal dose		0.75 L/ha = 150 g a.s./ha
type of study	:	Honeybee semi-field tunnel test	species	:	Honey bee (*Apis mellifera*)
year of execution	:	2008	test duration	:	29 d
GLP statement	:	No	exposure duration	:	14 d
Guideline	:	OEPP/EPPO guideline No. 170 (3), 2001	dosing method	:	Tunnel test in flowering *Phacelia tanacetifolia*, 1x foliar spray during flowering and active foraging of bees
test substance	:	BYI 02960 SL 200, Batch no. 2009-001162 Combined with Surfactant Antarox B/848, 150 g/ha	acceptability	:	Less reliable due to non-GLP
a.s. content	:	201.9 g flupyradifurone/L	Result	:	No adverse effect on mortality, flight intensity, brood development; Effects on behaviour not reported

Description

The study was conducted on the premises of Bayer CropScience AG's Experimental Station Höfchen, 51399 Burscheid, North Rhine-Westphalia, Germany.

The overall size of the test field was approximately 1000 m² (100 m x 10 m). The crop *Phacelia tanacetifolia* was drilled on 30 May 2009 at a sowing rate of 6 kg seeds/ha, by using a sowing machine. The *Phacelia*-seeds were not seed-treated and the crop has not received any maintenance treatment with plant protection products.

Two replicates (= two gauze tunnels) were set up for each experimental group (untreated control, two toxic references (Insegar with a.s. fenoxycarb and Actara with a.s. thiamethoxam) and test item), respectively. The tunnels were covered with gauze, preventing the bees from escaping but allowing for sufficient ventilation (mesh-size approx. 1.5 mm). The floor space of each tunnel was approximately 50 m^2 (5 m width x 10 m length). The distance between the tunnels was approx. 3 - 5 m. For each experimental group (control, test item and toxic references), two tunnels were set up in the field.

Honey bees of the race *Apis mellifera carnica* L. were obtained from a beekeeper and showed no obvious signs of Varroa- (last anti-Varroa treatment in November 2008) or Nosema infestation.

On 03 July 2009, one nucleus was prepared by taking 30 brood combs (size: 370 mm x 223 mm) from different bee colonies plus 10 food combs and honey bees, and placed into a multiple-storey hive with 4 supers. One queen was added.

On 6 July 2009, a sufficient quantity of 3-comb-hives were prepared by combining two brood combs from the nucleus (plus honey bees) with one empty frame, respectively. Finally, one queen was placed into each 3-comb-hive, containing approx. 2500 - 3000 honey bees. All queens of the employed experimental colonies (3-comb-hives, prepared as outlined above) used in this test were sisters. The assignment of the bee colonies to the tunnels (test units) followed a randomized complete block design.

The bee colonies were placed inside the tunnels after beginning of flowering on 7 July 2009 (DAA-2). During the applications care was taken not to directly overspray the colonies. The colonies were taken out of the tunnels on 22 July 2009 (DAA13, end of confinement period), at a growth stage, where the crop could not longer provide a sufficient food supply for the colonies (end of flowering). The colonies were transferred at the same day (DAA13) to a monitoring site, where the honey bees were free to forage. Final colony assessments were conducted on 6 August 2009 (DAA28).

Observations

The small honey bee colonies in all experimental groups were examined daily during the confined exposure period for effects on mortality, behaviour and foraging activity (14 days in succession, from DAA-1 until DAA12) and hive weight.

Honey bee colonies were relocated to a monitoring site on DAA13, where the bees were allowed to forage freely. Colony assessments included an assessment of colony strength, eggs, larvae, pupae, nectar- and pollen stores as well as hive weight were performed in regular intervals during and after the confined exposure period until DAA28 (last colony assessment).

Foraging activity was assessed by recording the number of honey bees foraging in two 1 m x 1 m observation squares marked in the crop inside each tunnel during the daily observation periods (duration: 2 min/square). In total, three assessments were carried out before and 28 assessments after the application.

The following parameters were expressed as percentage values per comb area on the study days DAA-0, DAA4, and DAA7 (during confinement), on DAA 14 (just after confinement, on the monitoring site) and on DAA 21 and DAA 28 (on the monitoring site).

- Nectar stores: The amount of sampled nectar was assessed by the estimation of the percentage of total comb area, on both sides of the comb, containing cells filled with nectar. The nectar storage was compared between control, test item and toxic references.
- Pollen stores: The amount of sampled pollen was assessed by the estimation of the percentage of total comb area, on both sides of the comb, containing cells with pollen. The pollen storage was compared between control, test item and toxic references.
- Egg-laying activity: The egg-laying activity of the queens was assessed by inspection of the brood combs. During each inspection, the percentage of total comb area was estimated on

both sides of the comb, containing cells with eggs. The egg deposition was compared between control, test item and toxic references.

- Breeding success: During each inspection, the percentage of total comb area was estimated on both sides of the comb, containing honey bee larvae and pupae (capped brood). Abundance of larvae and pupae (capped brood) was compared between control, test item and toxic references.
- Colony strength: During each inspection, the percentage of total comb area was estimated on both sides of the comb, which was covered by adult honey bees. This endpoint integrates potential impacts of the test item on breeding success, longevity and mortality of honey bees.
- Abundance of adult honey bees found on the combs was compared between control, test item and toxic references. A proportion of the adult bees of the hives could have been foraging at the moments of the assessment, but as the assessment of all experimental groups was conducted within a short period of time, it is assumed that this proportion is equal for all hives.
- Any behavioural anomalies, including e.g. exaggerated motility, aggressiveness, discoordinated movements (trembling, flight incapability, etc.), apathy, lethargic behaviour, clustering at the hive entrance, clustering on the gauze netting of the tunnel, obvious symptoms of intoxication (cramping, agony, etc.), whenever observed, were recorded with the date and daytime of observation.

Temperature and relative humidity was recorded during the confinement of the honey bees in the tunnels using a calibrated data logger inside one control tunnel from 07 July 2009 (DAA-2) until 21 July 2009 (DAA12), while rainfall was measured outside the control tunnel by means of a portable rain-gauge.

Results

Climatic conditions

Measured minimum temperatures (data logger) ranged between 10.4 and 16.3°C and maximum temperatures between 14.9 and 34.7°C, the minimum relative humidity (RH) ranged between 33.2 and 85.5% and the maximum RH between 93.2 and 105.6%.

<u>Mortality</u>

No adverse effects of the test item were found on worker bee-, drone- and pupal mortality, respectively. Results on mortality are reported in the following tables (copied from the report).

Table 9.4.2-2. Mortality (in front of the hives) after application of BYI 02960 SL 200 in combination with Surfactant Antarox B/848

EFSA asked RMS to provide more detailed data (i.e. for each repetition for each day) at least for adult and larvae/pupa mortality. The mortality data for adults and pupae for the individual hives are copied below from the study report (Tables 35, 37 and 38). Drone mortality is not presented since it was always 0.

DAA0ba = Day of application, before application

Foraging activity

Foraging activity is reported in the following table (copied from the report).

Table 9.4.2-4 Foraging activity of bees after application.

Time Interval	Untreated	Insegar	BYI 02960	Actara
Foraging activity (Daily average number of flower visits on 1 m² per experimental group)				
DAA-1	10.6	12.1	11.9	12.8
DAA0ba	12.8	12.8	16.3	19.0
DAA0aa	23.6	20.7	20.7	0.5
DAA1	14.8	13.0	15.3	1.8
DAA2 – DAA3	26.1	23.1	24.9	4.8
DAA4 – DAA6	52.3	49.7	53.5	3.3
DAA7 – DAA12	43.5	39.5	40.5	2.1

Foraging activity after application was comparable in the control, test item (as BYI 02960) and the toxic reference Insegar (as fenoxycarb), while foraging activity decreased strongly to very low levels in Actara (as thiamethoxam) group, respectively. Foraging activity in the Actara (as thiamethoxam) group had not recovered during the entire confinement period. In the test item group, foraging activity was slightly reduced immediately after the treatment when compared to control, but recovered fully within 1 – 2 hours after treatment and followed the control group at any point in time thereafter.

Weight development of the bee hives

Results for weight development are reported in the following figure (copied from the report).

Figure 9.4.2-9. Weight development of the bee hives (average value per experimental group).

During confinement, the hive weights in all experimental groups decreased due to the tunnel-specific limited foraging conditions. Just after the end of the confined exposure period (DAA14), hive weight in

all experimental groups was very similar. Except for the Actara group, hive weights increased in all other experimental groups thereafter, with the typical fluctuations for this variable endpoint under field condtions, once the bees were allowed to forage freely after confinement. At the last assessment on DAA28, hive weights in the Actara group had not recovered. No adverse effects of the test item were found on the hive weight development.

Number of honey bees on the tent wall

The average number of honey bees at the tent walls shortly before the actual treatment (DAA0ba) was low and comparable in all experimental groups. Immediately after the treatment (DAA0aa), the average number of honey bees at the tent walls remained comparable and low in all experimental groups. From DAA2 until DAA4, the average number of honey bees at the tent walls increased in all experimental groups, the highest average number was recorded in the afternoon of DAA4 and accounted to about 70 honey bees in the test item treatment and in the control group, respectively, with the overall highest recorded individual number in the test item treatment group. From DAA5 onwards, the average number of honey bees at the tent walls had decreased and remained until the end of the confinement period on a rather low and comparable level in all experimental groups, by showing the typical fluctuations for this parameter, with sometimes slightly higher numbers in the test item treatment group. In the Actara group, with a few exceptions only, consistently the lowest numbers of honey bees sitting at the tent walls were recorded throughout the entire confined post-application period.

No adverse effects of the test item were found.

Nectar stores

The total average comb area with cells containing nectar in % of the total comb area per experimental group, over time is reported in the following figure (copied from the report).

Figure 9.4.2-10. Nectar stores in % of the total comb area per experimental group (total average)

During confinement, the nectar stores in all experimental groups decreased due to the tunnel-specific limited foraging conditions. Just after the end of the confined exposure period (DAA14), nectar stores in all experimental groups were very similar. Except for the Actara group, nectar stores increased in all other experimental groups thereafter, with the typical fluctuations for this variable endpoint under field conditions, once the bees were allowed to forage freely after confinement. At the last assessment on DAA28, nectar stores in the Actara group had still not recovered. No adverse effects of the test item were found on nectar storage.

Pollen stores

The quantity of pollen stores found in the combs was recorded at regular intervals throughout the study period, starting on the day of application. The data are summarised in the following table (copied from the report).

Figure 9.4.2-11. Pollen stores in % of the total comb area per experimental group (total average)

Honey bee colonies in all experimental groups started with small amounts of pollen (DAA0ba), which motivated the bees to collect pollen also under the limited foraging condition during confined exposure. Throughout and just after the end of the confined exposure period (DAA14), pollen stores had increased in all experimental groups, except for the Actara group. Pollen stores increased in all experimental groups with the typical fluctuations for this variable endpoint under field conditions, once the bees were allowed to forage freely after confinement, however, on the last assessment day (DAA28), pollen stores in the Actara group had still not recovered compared to control. No adverse effects of the test item were found on pollen storage.

Population development and breeding performance

Egg-laying activity was assessed and recorded at regular intervals throughout the study

period, starting on the day of application. The data are presented in the following figure (copied from the report).

Figure 9.4.2-12. Comb area with cells containing eggs in % of the total comb area per experimental group (total average)

No adverse effects of the test item were found on egg-laying activity.

<u>Abundance of honey bee larvae</u>

Abundance of honey bee larvae was assessed and recorded at regular intervals throughout the study period, starting on the day of application. The data are presented in the following figure (copied from the report).

Figure 9.4.2-13. Comb area with cells containing larvae in % of the total comb area per experimental group (total average)

No adverse effects of the test item were found on honey bee larvae.

Abundance of honey bee pupae

Abundance of honey bee pupae (capped brood) was assessed and recorded at regular intervals throughout the study period, starting on the day of application. The data are presented in the following figure (copied from the report).

Figure 9.4.2-14. Comb area with cells containing pupae in % of the total comb area per experimental group (total average)

No adverse effects of the test item were found on honey bee pupae.

Total abundance of honey bee brood

The total abundance of honey bee brood was assessed and recorded at regular intervals throughout the study period, starting on the day of application. The data are presented in the following figure (copied from the report).

Figure 9.4.2-15. Comb area with cells containing brood in % of the total comb area per experimental group (total average)

No adverse effects of the test item were found on total brood abundance.

<u>Population development</u>

The size of the comb area covered with adult honey bees was assessed at regular intervals throughout the study period, starting on the day of application. The data are presented in the following figure (copied from the report).

Figure 9.4.2-16. Comb area covered with adult honey bees in % of the total comb area per experimental group (total average)

No adverse effects of the test item were found on population development.

Conclusions of the author

The results of the study revealed that BYI 02960 can be applied via foliar application at a rate corresponding to 150 g as/ha into a full-flowering and highly bee attractive crop, as represented here by *Phacelia tanacetifolia*, during honey bees actively foraging on the crop, without adverse effects on mortality, foraging activity, behaviour, brood-, food-, and population development as well as on overall hive vitality.

Remarks by RMS

A positive control was included in the test and showed that the test system was behaving as expected. Author concluded that behaviour was not affected. This could not be evaluated by RMS as observations on behaviour were not reported.

According to the EFSA Opinion on the Science behind the development of a risk assessment of plant protection products for bees (EFSA Journal 2012, 10: 2668, section 3.5.1), the main exposure route for bee brood is via pollen. Since *Phacelia tanacetifolia* is a major source of pollen, and pollen from uncontaminated sources was not present in the tunnels, the present test is suitable to show potential effect of flupyradifurone on brood related parameters, mortality and flight intensity.

The results of the study show that there were no test item related effects on mortality, foraging activity, brood-, food-, and population development as well as on overall hive vitality of honeybees after foraging on *Phacelia tanacetifolia* sprayed once with BYI 02960 SL200 (at an application rate corresponding to 150 g as/ha) together with a surfactant in a tunnel test. Behaviour effects cannot be evaluated as these data were not reported.

The results of this study can be considered for risk assessment but should be considered with caution as the study was not performed under GLP.

Expert discussion in Pesticide Peer Review meeting 124 (December 2014):

(Please note that the word ‘effect’ in the text below might be interpreted as different from the control (i.e. may or may not include effects from the treatment), pending on the context.)

Some possible effects on workers and larvae were observed. The second toxic reference (Insegar), normally used in bee brood studies, did not have consistent effect on the larvae in this study. This questions the results of the larvae assessments.

The experts agreed that the toxic references are only for demonstrating that the conditions of the study were suitable to detect effects. The results of the test items should not be compared to the results of the toxic reference.

The possible effect on workers was discussed in detail given that the increase in mortality was very low and could be only the natural variation. However, it was stressed that any increase should be considered. The effects were only apparent only just after application and not at later time points.

These apparent effects were only evident in front of the hive and not at the tunnel edge. The experts agreed that the level of effect on mortality was not of concern and did not affect the colony.

Study KIIIA 10.4.7/03

Characteristics

Reference	:	Rentschler,S. (2012a)	nominal dose		2x 1 L/ha = 200 g a.s./ha
type of study	:	Honeybee semi-field tunnel test	species	:	Honey bee (*Apis mellifera*)
year of execution	:	2009	observation duration	:	29 d
GLP statement	:	Yes	exposure duration	:	16 d
Guideline	:	OEPP/EPPO guideline No. 170 (3), 2001	dosing method	:	Tunnel test in flowering *Phacelia tanacetifolia*, 2x foliar spray. 1st 6 d before hive set-up (flowers in bud), second 10 d after 1st application during flowering and active foraging of bees
test substance	:	BYI 02960 SL 200 G, Batch no. 2009-001253.	acceptability	:	Acceptable
a.s. content	:	199.8 g flupyradifurone/L	Result	:	No adverse effect on mortality, behaviour , brood development. Adverse effect on flight intensity.

Description

The study was conducted in Niefern-Öschelbronn, federal state of Baden-Wuerttemberg, Germany on a field of flowering *Phacelia tanacetifolia*. The experimental design of this study comprised three experimental groups with three replicates each, 9 tunnel tents were set-up before moving the hives to the experimental field. The individual treatment groups, the respective application rates per ha and the respective spray volumes per ha are described in the following table (copied from the report).

Table 9.4.2-5. Treatment groups, application rates and spray volume.

Treatment Group	Code	Time of application	Application rate		Spray Volume
			[g a.s./ha]*	[g product/ha]	
Control (tap water)	C	DAA0, BBCH 65	None	None	200 L/ha
Test item (BYI 02960 SL 200 G)	T	DAA-10, BBCH 58	200	1 L	200 L/ha
		DAA0, BBCH 65	200	1 L	200 L/ha
Reference item	R	DAA0, BBCH 65	400	1 L	200 L/ha

DAA = days after 2nd test item application
* calculation based on the nominal content of a. s.

The reference item was Perfekthion EC 400 (a.s. dimethoate). The area covered per tunnel tent was 72 m^2. The dimensions of each tunnel tent (covered plot) were 12 m long, 6 m wide and 2.5 m high in

the centre. The tunnel tent frames were covered with light plastic gauze (mesh size: 1.5 mm). The distance between the tunnel tents was approximately 3 m. Before start of the test, alleys were created in each tunnel tent by removal of the plants and smoothing the ground. Subsequently, the alleys were covered with linen sheets of 0.6 m width (area covered approx. 13.7 m^2). About 0.5 m *Phacelia tanacetifolia* plants were removed along the tents to get the required size of the crop area that have to applied (size of boom sprayer: 2.2 m).

The 1st and the 2nd test item application were carried out inside the tunnel tents. One small bee colony was introduced per tunnel, 4 days before the 2nd application in T and the concurrent applications in C and R, respectively. After the end of the confined exposure period, the colonies were relocated to a monitoring site without intensive agriculture.

For the test, small healthy colonies with five combs were used. The colony size at set-up was in the range of approximately 4000 – 7000 bees. All nuclei were produced at the same time. The colonies were from one breeding line in order to guarantee uniform bee material in all treatments. Furthermore the following criteria for the nuclei were guaranteed:

- at least two brood combs containing eggs, larvae and capped cells;
- at least one comb containing honey and pollen;
- bees were free of Nosema and Varroa disease symptoms and other bee diseases

Wooden bee traps with gauze on bottom and on top were attached to the entrance of the nuclei in order to register those dead bees which were carried out of the hives.

The test item solution was prepared shortly before each application. The applications were carried out with a portable boom sprayer that simulates a commercial application. The following conditions were met for both applications:

- crop at BBCH 58, at 1st application in T; flowers still in bud
- crop at full bloom (BBCH 65), at 2nd application in T and the concurrent applications in C and R, respectively
- bees were actively foraging at 2nd application in T and the concurrent applications in C and R, respectively
- air temperature did not exceed 30°C (both application times)
- wind speed was less than 3 m/s at 1st application in T
- wind speed inside the tunnel tent was less than 2 m/s at 2nd application in T and the concurrent applications in C and R, respectively

During the 2nd application in T and the concurrent applications in C and R, respectively, the bee colonies were covered with plastic sheets and the water supply was moved out of the tunnels during the application to avoid direct contamination.

Bee traps with gauze on bottom and on top were attached to the entrance of the hives in order to register those dead bees which were carried out of the hives. The mortality assessments started 2 days before set up of the colonies inside the tunnels and lasted until the re-location of the hives to the monitoring location

Furthermore, mortality was recorded in the crop. To facilitate and standardise the mortality assessment in the crop, *Phacelia tanacetifolia* plants were removed prior to the set-up of the hives from the areas, moreover, water-permeable linen sheets were spread out on the ground. At each assessment, the dead bees found on the sheets and in the bee traps were counted and removed. The mortality of honeybees of the different treatment groups in the dead bee trap at the entrance of the hive and on the linen sheets were assessed prior to set up (DAA -6 to -4), prior to 2nd test item application (DAA -3 to -1), on the day of the 2nd test item application (before and after the application: 0ba and 0aa) and after the 2nd test item application (DAA 1 to 11).

Flight Intensity

At each assessment during the exposure period, the number of forager bees that were both foraging on flowering *Phacelia tanacetifolia* and flying over the crop were counted on a square of 1 m² for a short period of time (approximately 10-15 seconds). At each assessment time per plot, the square observed was chosen by chance.

Condition of the colonies, development of the bee brood.

The condition of the colonies and the development of the bee brood was checked five times during the test. The first colony assessment took place on day before set-up of the colonies inside the tunnels (DAA-5). The second colony assessment was done on DAA7. Three further colony assessments took place after re-location of the colonies to the monitoring site at weekly intervals (±1 day).

In order to record possible effects of the test item, the following parameters were assessed:

- Strength of the colony (number of bees estimated according to IMDORF & GERIG, 1999 and IMDORF et al., 1987)
- Presence of a healthy queen
- Visual assessment of the brood (estimation of the number of cells filled with eggs/larvae/pupae, according to IMDORF & GERIG, 1999 and IMDORF et al., 1987)

At each colony assessment, the comb area containing bees and cells with nectar, pollen, eggs, larvae and capped cells was estimated per comb side and the total number of bees and cells containing the brood stages, pollen and nectar on the comb were calculated. This was done for all combs per hive. Afterwards, the total values were calculated for each hive and assessment date.

Behaviour of the Bees

The behaviour of the bees on the crop and around the hive was assessed during the exposure period. The assessments were performed during the flight intensity assessments.

At least the following symptoms were checked in comparison to the control bees:

- Aggressiveness
- Intensive flying activity without landing on the crop
- Clustering at the bee hive entrance
- Intoxication symptoms

Recording of the Meteorological Data

For the entire exposure period the following climatic data were recorded by a weather station (non-GLP record; distance from the field site less than 5 km):

- air temperature (daily min/max)
- relative air humidity (daily min/max)

During applications and assessments, the following data were recorded at the field site (GLP record):

- cloud cover (estimated during application and assessments of flight intensity)
- air temperature, relative air humidity (only during the application)
- wind speed (only during the application)
- rainfall (rain gauge placed tunnel C2)

Collection of Flowers

On DAA0aa1 and DAA7, flowers of *Phacelia tanacetifolia* were collected. Samples from the control tunnels were taken first, followed by the samples from the test item tunnels. No samples were taken in the reference item tunnels.

The terminal inflorescences with open flowers was cut at the end of the stipe and bagged. A pooled sample comprising ≥ 10 g flowers per treatment was collected from at least 12 different locations across the tunnel. Each sample was divided into two sub-samples (A and B).

Each sample was labelled twice with the following information: study code, treatment, number of replicate, type of sample and date of sampling.

Collection of Pollen from Combs

On DAA7 one pollen sample per tunnel (excluding the reference item tunnel) was taken from the hives. Samples from the control tunnels were taken before those of the test item tunnels.

Each sample was divided into two sub-samples in order to get one A (residue analysis) and one B sample (retained).

Each sub-sample contained enough *Phacelia tanacetifolia* pollen (dark purple) for analysis procedure. The pollen was collected with a pollen lifter which takes the pollen directly from the cell.

Each sample was labelled twice with the following information: study code, treatment, number of replicate, type of sample and date of sampling.

Collection of Nectar from Combs

One nectar sample per tunnel (excluding the reference item tunnel) was taken from the hives on DAA7. Samples from the control tunnels were taken before those of the test item tunnels.

Each sample was divided into two sub-samples in order to get one A (residue analysis) and one B sample (retained).

Each sub-sample contained enough *Phacelia tanacetifolia* nectar for analysis procedure. The nectar was collected by means of a table spoon which was pushed into the wax covered nectar cells.

Statistical analysis

The data of mortality and flight intensity of the test item and the reference item group were compared to the control in two separate approaches. The data were tested for normality and homoscedasticity using Shapiro-Wilk test ($p > 0.05$) and folded F-test ($p > 0.05$), respectively. Data were statistically compared using t-test (method pooled, $p \leq 0.5$) in case of normality and homoscedasticity. In case of no homoscedasticity but proven normality t-test was conducted with method Satterthwaite (same as Welch's t-test, $p \leq 0.5$). In case of no normality and no homoscedasticity Wilcoxon test ($p \leq 0.5$) was

used. Log-transformation was conducted if necessary to achieve better normatlity and homoscedascity of data.

Results

Climatic conditions

Temperature during 2rd application (July 19) was between 12.9 and 20.8.°C, 56.1-85.9 RH, 0.3 mm rainfall; Temperature during observation ranged from 10.5 to 31.7 °C. Rainfall 1.5 mm 1 day after 2rd application and 10 mm 5 days after 2rd application. Maximally 3 mm per day afterwards.

Mortality

Mortality of the different test groups are reported in the following figure (copied from the report). Significant increase of mortality was observed at DAA1. At most other days between DAA0aa and DAA11 mortality was increased although not significantly.

* = statistically significant (higher, R versus C; t-test, method pooled, two-sided, α = 0.05).
\# = statistically significant (higher, T versus C; t-test, method pooled, two-sided, α = 0.05).
0ba = before application
0aa = after application

Figure 9.4.2-17. Mean mortality values of the control group C, the test item group T and the reference group R prior to and after the 2nd application in T and concurrent applications in C and R.

EFSA asked RMS to provide more detailed data for adult and larvae/pupa mortality. The mortality data for dead bees for the individual hives are copied below from the study report (Tables 14, 15 and 16). The study report does not provide separate data for adults and pupae.

DAA = days after 2nd application in T
n. a. = not assessed (no linen sheet at the monitoring site)
LS = Linen sheet
aa = after application
ba = before application
BT = Dead bee trap
STD = Standard deviation
∑ = sum
Ø = mean value
1) = calculated for the daily mean values
2) = calculated over cumulative values (∑)/day
3) = for details concerning the calculation of the quotient of mortality (QM) see chapter 6.9
* = statistically significant

Flight intensity

Flight intensity was significantly reduced at days DAA0 and DAA2. Asterisks were however forgotten in the figure below. A reduced flight activity in T was observed from DAA0aa up to and including DAA3.

* = statistically significant (lower, R versus C; t-test, method pooled, two-sided, α = 0.05).
\# = statistically significant (lower, T versus C; t-test, method pooled, two-sided, α = 0.05).
0ba = before application
0aa = after application

Figure 9.4.2-18. Mean flight intensity values of the control group C, the test item group T and the reference group R prior to and after the 2nd application in T and concurrent applications in C and R.

Strength of the colonies

The mean number of bees assessed before set-up of the hives (first colony assessment) in the tunnels revealed a comparable colony strength in treatment groups C T and R. At the second colony assessment, during the confined exposure period, on DAA7, the mean number of bees was higher in the treatment groups C and T, whereas the mean number of bees in the reference item group was reduced (C: 6438, T: 5854, R: 3188). At the subsequent colony assessment, after the end of the confined exposure period outside the tunnels on DAA13 (third colony assessment), the mean number of bees further increased to 6896 bees/hive for C and 6750 bees/hive for T. At the two following colony assessments on DAA21 (fourth colony assessment) and DAA29 (fifth colony assessment), the mean number of bees for C and T was slightly decreased compared to the third colony assessment (C: 5771 bees/colony on DAA21 and 5229 bees/colony on DAA29; T: 5167 bees/colony on DAA21 and 6000 bees/colony on DAA29).

The development of colony strength was comparable between C and T throughout the study period and showed the fluctuations which are typical for this endpoint. Overall, no test item related adverse effects on colony strength were observed.

Figure 9.4.2-19. Mean number of bees in the treatment groups C, T and R at 5 colony assessment dates. Figure compiled by RMS from three tables in the report.

Figure 9.4.2-20. Mean number of brood and food cells in the treatment groups C, T and R at 5 colony assessment dates. Figure compiled by RMS from three tables in the report.

Development of Brood

The brood development was comparable between the control and the test item treatment colonies, the differences were within the range of natural variation. No test item related adverse effects on brood development were observed.

EFSA asked RMS to provide more detailed data on the larvae/pupae abundance.

Numbers of larvae on the five subsequent colony assessment days were 2267, 2267, 3000, 3333, 1333 in the control; 3067, 2200, 1733, 3067, 1933 in the treatment; and 1867, 467 in the reference group.

The mean abundance of brood (sum of cells containing eggs, larvae, and pupae) assessed before set-up of the hives (first colony assessment) was 10933 cells/hive for C, 13267 cells/hive for T and 10733 cells/hive for R. At the second colony assessment, during the confined exposure period, 7 days after application (DAA7), the mean abundance of brood in C and T decreased slightly, but synchronously (9000 cells/hive for C and 10133 cells/hive for T), whereas the mean abundance of brood in R decreased strongly to 3200 cells/hive. On the third colony assessment day (DAA13, thirteen days after the second application), the mean abundance of brood in C and T was 9000 cells/hive for C with STD 917 and 7600 cells/hive with STD 4303 for T. After one honey bee brood cycle, i.e. 3 weeks after the 2nd test item application (fourth colony assessment, DAA21), the mean abundance of brood in C and T was almost identical (10799 cells/hive for C and 10400 cells/hive for T), the same holds true for the last colony assessment (fifth colony assessment, DAA29: 12733 cells/hive for C and 14000 cells/hive for T). Overall, the brood development was comparable between the control and the test item treatment colonies, the differences were within the range of natural variation. No test item related adverse effects on brood development were observed.

Based on these numbers and because on the first, second, fourth and fifth colony assessment day, there is clearly no effect on total number of brood cells (numbers either equal or higher in T), RMS considers that there is no adverse effect on brood development.

The brood assessment data for the individual hives are shown below, in tables copied from the study report (Tables 20, 21 and 22).

Development of the Food Storage Area

The observed decrease in food stores in both, test item treatment and control during confinement as well as the subsequent increase can be considered as typical for this type of study. The decrease of the mean extent of food stores on the last assessment day (DAA29) can be explained by the advanced season. No test-item related adverse effects on the development of the food storage area were observed.

Behaviour of the Bees

Clustering at the hive entrance on DAA1 in hive C3 and on DAA10 in hive T1 was observed. No further abnormal behaviour was recorded in the control and in the test item treatment group, respectively. After the application of the reference item, a strong repellence effect (no or low flight activity on the crop) as well as several bees with obvious signs of intoxication were observed in the reference item group.

Residues in flowers

Residues in flowers are given in Table 9.4.2-6.

Table 9.4.2-6. Residues of BYI02960 and BYI 02960-DFEAF in flowers after application of BYI 02960 SL 200 at 200g as/ha

Conclusions of the author

A pre-flowering foliar application of the test item, corresponding to 200 g BYI 02960 as/ha to a highly bee-attractive crop (*Phacelia tanacetifolia*), was followed by a further foliar application of the test item, corresponding to 200 g BYI 02960 as/ha, during full-flowering with honey bees actively foraging on the crop.

This application scenario did not cause treatment-related adverse effects on mortality, on brood and food development as well as on colony vitality under forced exposure conditions.

A slight repellent effect of the test item was indicated by a reduced flight intensity on the day of the 2nd test item application (DAA0aa) as well as on DAA1 and DAA2. From DAA3 onwards, the flight intensity in the test item treatment was comparable to the control.

Remarks by RMS

A positive control was included in the test and showed that the test system was behaving as expected. On DAA1, the mean mortality in the test item treatment group was slightly, but statistically significantly higher than in the control group (t-test, method pooled, one-sided, α = 0.05; number of dead bees: 4.0, 18.0, and 290.7 for C, T, and R, respectively). In the total post application period however, the mean daily mortality was recorded to be 10.4, 14.3, and 151.2 for C, T, and R, respectively and there is no significant difference between the treatment and the control. Since the total mortality in the treatment on day 21(18 out of a mean of 5063 bees (mean), corresponds to a mortality < 0.4%, the RMS considers this effect to be negligible.

According to the EFSA Opinion on the Science behind the development of a risk assessment of plant protection products for bees (EFSA Journal 2012, 10: 2668, section 3.5.1), the main exposure route for bee brood is via pollen. Since *Phacelia tanacetifolia* is a major source of pollen, and pollen from uncontaminated sources was not present in the tunnels, the present test is suitable to show potential effect of flupyradifurone on brood related parameters, mortality and flight intensity.
The results of the study show that there is no (or a negligible) adverse effect on mortality, on brood and food development as well as on colony vitality of the honeybees after foraging on *Phacelia tanacetifolia* sprayed once with BYI 02960 during pre-flowering and once during full-flowering at an application rate corresponding to 200 g as/ha in a tunnel test except for a reduced flight intensity on the day of the second application and the two following days. The results of this study, including the residue measurements, can be used in the risk assessment.

Expert discussion in Pesticide Peer Review meeting 124 (December 2014):
(Please note that the word 'effect' in the text below might be interpreted as different from the control (i.e. may or may not include effects from the treatment), pending on the context.)

The experts noted that the colony size at the study initiation was reasonable (approx. 7000 bees). Only visual inspections were used to assess the combs.

Fewer larvae were observed in the treated groups on assessment day 3. Fig. B.4.2-20 (DAR). These effects could be within natural variation but effects of the test item could not be excluded also. In addition, there was also an increase in forager mortality, as noted by the RMS, just after application (day 1 and day 0).

It was noted that it was difficult to interpret the results of the study from visual inspection of the figures alone. The actual numbers (in the tables) need to be considered also.

Overall, there was no disagreement with the RMS's assessment.

Description

The study was conducted in Kværs, near Sønderborg, Region Syddanmark, Denmark on a field of flowering *Phacelia tanacetifolia*. The experimental design of this study comprised three experimental groups with three replicates each, 9 tunnel tents were set-up before the 3rd application in T and the concurrent applications in C and R, respectively. The individual treatment groups, the respective application rates per ha and the respective spray volumes per ha are described in the following table (copied from the report).

Table 9.4.2-7. Treatment groups, application rates and spray volume.

Treatment group	Code	Time of application	Application rate		Spray volume
			[g a.s./ha]*	[g product/ha]	
Control (tap water)	C	DAA0, BBCH 65	None	None	200 L/ha
Test item (BYI 02960 SL 200 G)	T	On the day of sowing, before sowing, BBCH 00	300	1.5 L	200 L/ha
		DAA -7, BBCH 60	200	1 L	200 L/ha
		DAA0, BBCH 65	200	1 L	200 L/ha
Reference item	R	DAA0, BBCH 65	400	1 L	200 L/ha

DAA = days after 3rd test item application in T
* calculation based on the nominal content of a. s.

The reference item was Perfekthion EC 400 (a.s. dimethoate). The total area covered per tunnel tent was 60 m^2. The dimensions of each tunnel tent (covered area) was 12 m long, 5 m wide; the height of the tunnel in its centre was 3.5 m.

The 1st and the 2nd test item application were conducted on three replicate plots with 12 m width and 20 m length. The 3rd test item application was carried out inside the tunnel tents. One small bee colony was introduced per tunnel, 3 days before the 3rd application in T and the concurrent applications in C and R, respectively. After the end of the confined exposure period (10 d; 7 days after 3rd application), the colonies were relocated to a monitoring site without intensive agriculture.

For the test, small healthy colonies with ten combs were used. The colony size at set-up was in the range of approximately 1000 – 9000 bees (on DAA-3: control mean size 1337 bees, treatment mean size 4274 bees, reference group mean size 3065 bees). All nuclei were produced at the same time. The colonies were from one breeding line and as similar to one another as possible. Furthermore the following criteria for the nuclei were guaranteed:

- 3 - 6 brood combs containing eggs, larvae and capped cells;
- 5 - 10 combs containing honey and pollen;
- bees were free of Nosema and Varroa disease symptoms and other bee diseases

Wooden bee traps with gauze on bottom and on top were attached to the entrance of the nuclei in order to register those dead bees which were carried out of the hives. Set-up of the hives was three days before the 3rd application in T and the concurrent applications in C and R, respectively.

The test item solution was prepared shortly before each application. The applications were carried out with a portable boom sprayer that simulates a commercial application. Immediately after the 1st test item application, the test item was incorporated into the soil of the treatment plots to a depth of approximately 15 cm. At the same day - after application and incorporation of the test item and collection of the soil samples - *Phacelia tanacetifolia*-seeds were sown. The following conditions were met for application:

- cropless soil at 1st application in T (43 d before 2nd application)
- crop at BBCH 60, at 2nd application in T (7 d before 3rd application)
- crop at full bloom (BBCH 65), at 3rd application in T and the concurrent applications in C and R, respectively
- bees were actively foraging at 3rd application in T and the concurrent applications in C and R, respectively
- air temperature did not exceed 30°C (all applications)
- wind speed was 0.5 m/s at 1st application in T
- wind speed was 0.0 m/s at 2nd application in T
- wind speed inside the tunnel tents was 1-2 m/s at 3rd application in T and the concurrent applications in C and R, respectively (2-3 m/s during application in R).

During the 3rd test item application as well as during the concurrent application of tap water and the reference item, the bee colonies were covered with plastic sheets and the water supply was moved out of the tunnels until the end of application to avoid direct contamination. After the application of each plot the volume applied was determined by measuring the remaining spray solution.

Bee traps with gauze on bottom and on top were attached to the entrance of the hives in order to register those dead bees which were carried out of the hives. The mortality assessments started 3 days before set up of the colonies inside the tunnels and lasted until the re-location of the hives to the monitoring location.

Furthermore, mortality was recorded in the crop. To facilitate and standardise the mortality assessment in the crop, *Phacelia tanacetifolia* plants were removed prior to the set-up of the hives from the areas, moreover, water-permeable linen sheets were spread out on the ground. At each assessment, the dead bees found on the sheets and in the bee traps were counted and removed. The mortality of honeybees of the different treatment groups in the dead bee trap at the entrance of the hive and on the linen sheets were assessed prior to set up (DAA -6 to -3), prior to the 3rd test item application (DAA -2 to -1), on the day of the 3rd test item application (before the application (Oba) and 1 h, 2h, 4h and 6h after the application (0aa)) and after the 3rd test item application DAA 1 to 3 (2 times a day at approximately the same time) and DAA 4 to 7 (once a day about the same time of the day in the morning up to noon).

Flight Intensity

At each assessment during the exposure period, the number of forager bees that were both foraging on flowering *Phacelia tanacetifolia* and flying over the crop were counted on a square of 1 m² for a short period of time (approximately 10-15 seconds). At each assessment time per plot, the square observed was chosen by chance.

Condition of the colonies, development of the bee brood.

The condition of the colonies and the development of the bee brood were checked five times during the test. The first colony assessment took place shortly before set-up of the colonies inside the tunnels (DAA-3). The second colony assessment was done on DAA7. Three further colony assessments took place after re-location of the colonies to the monitoring site at weekly intervals (±1 day).

In order to record possible effects of the test item, the following parameters were assessed:

- Strength of the colony (number of bees estimated according to IMDORF & GERIG, 1999 and IMDORF et al., 1987)
- Presence of a healthy queen
- Visual assessment of the brood (estimation of the number of cells filled with eggs/larvae/pupae, according to IMDORF & GERIG, 1999 and IMDORF et al., 1987)
- Visual assessment of the food (estimation of the number of cells filled with pollen/nectar, according to IMDORF & GERIG, 1999 and IMDORF et al., 1987)

At each colony assessment, the comb area containing bees and cells with nectar, pollen, eggs, larvae and capped cells was estimated per comb side and the total number of bees and cells containing the brood stages, pollen and nectar on the comb were calculated. This was done for all combs per hive. Afterwards, the total values were calculated for each hive and assessment date.

Behaviour of the Bees

The behaviour of the bees on the crop and around the hive was assessed during the exposure period. The assessments were performed during the flight intensity assessments.

At least the following symptoms were checked in comparison to the control bees:

- Aggressiveness
- Intensive flying activity without landing on the crop
- Clustering at the bee hive entrance

- Intoxication symptoms

Recording of the Meteorological Data

For the entire exposure period the following climatic data were recorded by a weather station (GLP record):

- air temperature (daily min/max)
- relative air humidity (daily min/max)

During applications and assessments, the following data were recorded at the field site (GLP record):

- cloud cover (estimated during application and assessments of flight intensity)
- air temperature, relative air humidity (only during the application)
- wind speed (only during the application)
- rainfall (rain gauge placed in one tunnel)

Soil Sample for Residue Analysis

2 x 10 soil cores were taken on each of the with BYI 02960 SL 200G treated plots, after the 1st test item application and immediately after incorporation of the test item into the soil (i.e. before sowing *Phacelia tanacetifolia* seeds). Subsequent to the sampling, *Phacelia tanacetifolia* seeds were sown. Soil samples consisted of soil cores with a diameter of 50 mm that have been taken to a depth of 20 cm. The soil cores per individual plot (in total there were three BYI 02960 SL 200G treated plots) and sub-sample were pooled; 10 cores were used and pooled for residue analysis (i.e. sub-sample A) and 10 cores were used and pooled as a retained sample (sub-sample B). No soil samples were taken on the control and reference plots.

Collection of Flowers

On DAA0aa1 and DAA7, flowers of *Phacelia tanacetifolia* were collected. Samples from the control tunnels were taken first, followed by the samples from the test item tunnels. No samples were taken in the reference item tunnels.

The terminal inflorescences with open flowers was cut at the end of the stipe and bagged. A pooled sample comprising ≥ 10 g flowers per treatment was collected from at least 12 different locations across each tunnel. Each sample was divided into two sub-samples (A and B, each sub-sample containing ≥ 5 g).

Collection of Pollen from Combs

One pollen sample per tunnel (excluding the reference item tunnel) was taken from the hives on DAA7. Samples from the control tunnels were taken before those of the test item tunnels. The pollen was collected with a pollen lifter which takes the pollen directly from the cell. Each sample was divided into two sub-samples in order to get one A (residue analysis) and one B sample (retained).

Collection of Nectar from Combs

One nectar sample per tunnel (excluding the reference item tunnel) was taken from the hives on DAA7. Samples from the control tunnels were taken before those of the test item tunnels.

The nectar was collected by means of a table spoon which was pushed into the wax covered nectar cells.

Residue analysis in honeybee products and flowers

Residue analysis of BYI 02960 and its relevant metabolite(s) in flower, nectar, pollen and soil was performed by using High Performance Liquid Chromatography (HPLC), coupled with electrospray and tandem mass spectrometry (MS/MS) detection.

Statistical analysis

The data of mortality and flight intensity of the test item and the reference item group were compared to the control in two separate approaches. The data were tested for normality and homoscedasticity using Shapiro-Wilk test ($p > 0.05$) and folded F-test ($p > 0.05$), respectively. Data were statistically compared using t-test (method pooled, $p \leq 0.5$) in case of normality and homoscedasticity. In case of no homoscedasticity but proven normality t-test was conducted with method Satterthwaite (same as Welch's t-test, $p \leq 0.5$). In case of no normality and no homoscedasticity Wilcoxon test ($p \leq 0.5$) was used

Results

Climatic conditions

Temperature during 3rd application was between 11.6 and 34.3.°C, 31-100% RH, no rainfall; Temperature during observation ranged from 9.2 to 36.6 °C. Rainfall 6.5 mm 1 day after 3rd application and 3.5 mm 6 days after 3rd application.

<u>Mortality</u>

Mortality of the different test groups is reported in the following figure (copied from the report).

F

igure 9.4.2-21. Mean number of dead bees (worker bees, larvae and pupae)/treatment group/day counted in the dead bee traps and on the linen sheets prior to and after the 3rd test item application.

* = statistically significant (lower);

0ba = day of application;

0aa = after 3rd test application in T and the concurrent applications in C and R, respectively.

Mortality in the treatment was higher throughout the entire assessment period, but was only significant at DAA6. The high number of dead bees in R during the post application period shows the sensitivity of the test system and was statistically significantly increased from DAA0aa to DAA5. According to author, the higher number of bees in the test item treatment group was the result of a higher turnover of the more stronger colonies in terms of mortality rates (at set-up, control colonies comprised on average 1337 bees [range: 816 - 2254], treatment colonies comprised on average 4274 bees [range: 1503 - 9192]).

Flight intensity

Figure 9.4.2.22 presents the mean flight intensity in the treatments groups C, T and R. On the day of the 3rd application (DAA0aa), on the day after this application (DAA1) and from DAA3 to 5 slight reductions in flight intensity were found in the test item group T when compared to the control group (T). Only on DAA5, the flight intensity was statistically significantly lower in T when compared to C.

Figure 9.4.2.22. Mean number of forager bees/m^2 inside the tunnels for C (control), T (treatment) and R (reference) prior to and after the 3rd application in T.

* = statistically significant (lower);

0ba = day of application;

0aa = after 3rd test application in T and the concurrent applications in C and R, respectively.

Strength of the colonies

Results concerning the condition of the colonies are reported in the following two figures. Figures are compiled from the original tables in the report. The 1st and 2nd colony assessment were made during confined tunnel situation.

Increases in number of bees were observed at the 3rd colony assessment. According to the author, the observed decrease in the average number of bees in T during the confined exposure conditions can be explained by limited forage. The limited forage was, however, sufficient for the smaller colonies in C. They showed an increase of colony strength at the 2nd colony assessment.

Figure 9.4.2-23. Mean number of bees in the treatment groups C, T and R at 5 colony assessment dates (DAA-3, DAA7, DAA14, DAA20 and DAA28 , resp.). Figure compiled by RMS from three tables in the report.

Figure 9.4.2-24. Mean number of brood and food cells in the treatment groups C, T and R at 5 colony assessment dates (DAA-3, DAA7, DAA14, DAA20 and DAA28 , resp.). Figure compiled by RMS from three tables in the report.

Mean abundance of brood (eggs, larvae and capped brood) showed an increase for C and T during the whole study period. In hives of R a decrease was observed at the second assessment date, followed by an increase at the fourth and fifth assessment day (7 and 13 days, respectively, after re-location of the hives to the monitoring site).

The mean extent of food stores in the colonies (sum of cells containing nectar and pollen) assessed before set-up of the hives (first colony assessment) was 19933 cells/hive for C, 18867 cells/hive for T and 15000 cells/hive for R. At the second colony assessment, during the confined exposure period, on

DAA7, the mean extent of food stores in the colonies C, T and R decreased synchronously (14667 cells/hive for C, 14440 cells/hive for T and 13600 cells/hive for R). At the subsequent colony assessment, after the end of the confined exposure period outside the tunnels (third colony assessment), the mean extent of food stores in the colonies C and T increased again to 15600 cells/hive for C and 16667 cells/hive for T. Increases at the fourth and fifth assessment days were comparable between C and T.

Accoring to the author, the observed decrease in food stores in both, treatment and control, during confinement as well as the subsequent increase can be considered as typical for this type of study. No test-item related adverse effects on the development of the food storage area were observed.

Behaviour of the Bees

No abnormal behaviour was recorded in the control group. Bees of one of the hives in the test item treatment group were clustering at the hive entrance on the day of the 3rd test item application during the two last assessments. From DAA1 until the end of the confinement period on DAA7, no abnormal behaviour of the bees was observed in all three replicates of T. After the application of the reference item, a strong repellence effect (no or low flight activity on the crop) as well as several bees with obvious signs of intoxication were observed in the reference item group.

Residue Analysis

The residue levels of BYI02960 and BYI02960-DFEAF in all control flower, control pollen and control nectar samples were below the Limit of Quantitation (LOQ) of 1 µg/kg.

Residues in flower, pollen and nectar of treated samples are given in the Table below.

Table 9.4.2-8. Residues of BYI 02960 and its metabolite BYI 02960-DFEAF in flower, pollen, nectar and soil.

Sample material	Sample interval	Residue BYI 02960 [µg/kg]	Residue BYI 02960-DFEAF [µg/kg]
Flower	0 DAA3	37592	78
	7 DAA3	199	9
Pollen (combs) (3 samples)	7 DAA3	3025, 6109, 8144	7, 13, 20
Nectar (combs) (3 samples)	7 DAA3	15, 18, 31	< LOQ
Soil (3 samples)	0 DAA1	36, 51, 67	< LOQ*

* Analysis was not conducted under GLP

Conclusions of the author

The application scenario used in this study did not cause treatment-related adverse effects on mortality, no effects on brood and food development as well as on colony vitality under forced exposure conditions.

A slight repellent effect of the test item was observed on the day of the 3rd test item application, after the treatment, as well as on DAA1 and from DAA3 to 5.

Remarks by RMS

A positive control was included in the test and showed that the test system was behaving as expected. According to the EFSA Opinion on the Science behind the development of a risk assessment of plant protection products for bees (EFSA Journal 2012, 10: 2668, section 3.5.1), the main exposure route for bee brood is via pollen. Since *Phacelia tanacetifolia* is a major source of pollen, and pollen from uncontaminated sources was not present in the tunnels, the present test is suitable to show potential effect of flupyradifurone on brood related parameters, mortality and flight intensity.
A draw-back of the study is that smaller colonies were set up in the control treatment. According to the author these smaller colonies were able to grow during confinement in the tunnel, whereas the larger colonies seemingly were restricted in their growth by limited forage. As the hives were not assigned to the three treatments correctly, it is not possible to evaluate whether reduction of growth in the flupyradifurone treatment was caused by the active substance or by restriction of forage.
The incorrect assignment of hives to the three treatments also causes problems with the interpretation of flight behaviour and mortality. The first two colony assessment dates are at DAA-3 and DAA7. Within this period the mean number of bees increases rapidly in the control hives (Figure 9.4.2-23). In Figure 9.4.2.22 it shows that at DAA0aa and DAA1 (in between the first two colony assessment dates) a lower flight intensity is present in the treatment. It is, however, not possible to judge the relation between flight intensity at DAA0aa and DAA1 and the numbers of bees at these dates. If numbers of bees in the control hives are still much lower than in the treatment, the data on flight intensity in Figure 9.4.2-22 are based on unequal bee numbers. It is concluded that the statistical analysis is not reliable. It is possible that Figure 9.4.2-22 is an underestimation of the effect on mortality in the treatment.
As the effects on bees of this study cannot be evaluated correctly, they cannot be used in risk assessment. The residue measurements can be used in the risk assessment.

Expert discussion in Pesticide Peer Review meeting 124 (December 2014):
(Please note that the word ‘effect’ in the text below might be interpreted as different from the control (i.e. may or may not include effects from the treatment), pending on the context.)

The RMS did not consider this study as valid for risk assessment. The reason for this was that the size of the control colonies differed from the test item colonies at the study initiation.

The experts agreed with the assessment of the RMS.

Study KIIIA 10.4.7/05

Characteristics

Reference	:	Pröbsting, A. (2012b)	nominal dose		1x 1.5 L/ha = 300 g a.s./ha 2x 1 L/ha = 200 g a.s./ha
type of study	:	Honeybee semi-field tunnel test	species	:	Honey bee (*Apis mellifera*)
year of execution	:	2011	observation duration	:	33 d
GLP statement	:	Yes	exposure duration	:	12 d
Guideline	:	OEPP/EPPO guideline No. 170 (4), 2001	dosing method	:	Tunnel test in flowering *Phacelia tanacetifolia*, 1x soil application, 2x

					foliar spray: 1st foliar application 14 d before hive set-up and 2nd foliar application 4 d after hive set-up during flowering and active foraging of bees
test substance	:	BYI 02960 SL 200 G, Batch no. 2010-007173	acceptability	:	Acceptable
a.s. content	:	198.6 g flupyradifurone /L	Result	:	No adverse effect on mortality and brood development. Adverse effect on flight intensity and behaviour.

Description

The study was conducted in Poggio Renatico, province of Ferrara, in the region Emilia Romagna, Italy on a field of flowering *Phacelia tanacetifolia*. The experimental design of this study comprised three experimental groups with three replicates each, 9 tunnel tents were set-up 4 days before the 3rd application in T and the concurrent applications in C and R, respectively. The individual treatment groups, the respective application rates per ha and the respective spray volumes per ha are described in the following table (copied from the report).

Table 9.4.2-9. Treatment groups, application rates and spray volume.

Treatment group	Code	Time of application	Application rate		Spray volume
			[g a.s./ha]*	[g product/ha]	
Control (tap water)	C	DAA0, BBCH 63-68	None	None	200 L/ha
Test item (BYI 02960 SL 200 G)	T	On the day of sowing, before sowing, BBCH 00	300	1.5 L	200 L/ha
		DAA-18, BBCH 58-61	200	1 L	200 L/ha
		DAA0, BBCH 63-68	200	1 L	200 L/ha
Reference item	R	DAA0, BBCH 63-68	400	1 L	200 L/ha

DAA = days after 3rd test item application
* calculation based on the nominal content of a. s.

Reference item was Perfekthion (a.s. dimethoate). The total area covered per tunnel tent was 60 m^2. The 1st and the 2nd test item application were conducted on three replicate plots with 10 m width and 20 m length. The 3rd test item application was carried out inside the tunnel tents. One small bee colony was introduced per tunnel, 4 days before the 3rd application in T and the concurrent applications in C and R, respectively. After the end of the 12-d confined exposure period (7 days after the 3rd test item application), the colonies were relocated to a monitoring site without intensive agriculture.

For the test, small healthy colonies with 6 combs were used. The colony size at set-up was in the range of approximately 7000-13800 bees. All nuclei were produced at the same time. The colonies were from one breeding line in order to guarantee uniform bee material in all treatments. Furthermore the following criteria for the nuclei were guaranteed:

- 3 - 6 brood combs containing eggs, larvae and capped cells;
- 5 - 6 combs containing honey and pollen;
- bees were free of Nosema and Varroa disease symptoms and other bee diseases

The test item solution was prepared shortly before each application. The applications were carried out with a portable boom sprayer that simulates a commercial application.

Immediately after the 1st test item application, the test item was incorporated into the soil of the treatment plots to a depth of approximately 8-10 cm. At the same day - after application and incorporation of the test item and collection of the soil samples - *Phacelia tanacetifolia*-seeds were sown. The following conditions were met for application:

- cropless soil at 1st application in T (unknown number of days before 2nd application)
- crop at BBCH 58-61, at 2nd application in T (18 d before 3rd application)
- crop at full bloom (BBCH 63-68), at 3rd application in T and the concurrent applications in C and R, respectively
- bees were actively foraging at 3rd application in T and the concurrent applications in C and R, respectively
- air temperature did not exceed 30°C (all applications)
- wind speed was 0 m/s at 2nd application in T
- wind speed inside the tunnel tents was 0 m/s at 3_{rd} application in T and the concurrent applications in C and R, respectively.

During the 3rd application in T and the concurrent applications in C and R, respectively, the bee colonies were covered with plastic sheets. After the application of each plot, the volume applied was determined by measuring the remaining spray solution.

Mortality

Mortality was recorded in the crop. At each assessment, the dead bees found on the sheets and in the bee traps were counted and removed. The mortality of honeybees of the different treatment groups in the dead bee trap at the entrance of the hive and on the linen sheets were assessed prior to set up (DAA -19 to -5), prior to the 3rd test item application (DAA -4 to -1), on the day of the 3rd test item application (before the application (Oba) and 1 h, 2h, 4h and 6h after the application (0aa)) and after the 3rd test item application DAA 1 to 3 (2 times a day at approximately the same time) and DAA 4 to 7 (once a day about the same time of the day in the morning up to noon).

Flight Intensity

At each assessment during the exposure period, the number of forager bees that were both foraging on flowering *Phacelia tanacetifolia* and flying over the crop were counted on a square of 1 m² for a short period of time (approximately 10-15 seconds). At each assessment time per plot, the square observed was chosen by chance.

Condition of the colonies, development of the bee brood.

The condition of the colonies and the development of the bee brood was checked five times during the test. The first colony assessment took place shortly before set-up of the colonies inside the tunnels

(DAA-5). The second colony assessment was done on DAA7. Three further colony assessments took place after re-location of the colonies to the monitoring site at weekly intervals.

In order to record possible effects of the test item, the following parameters were assessed:

- Strength of the colony
- Presence of a healthy queen
- Visual assessment of the brood (estimation of the number of cells filled with eggs/larvae/pupae)
- Visual assessment of the food (estimation of the number of cells filled with pollen/nectar)

At each colony assessment, the comb area containing bees and cells with nectar, pollen, eggs, larvae and capped cells was estimated per comb side and the total number of bees and cells containing the brood stages, pollen and nectar on the comb were calculated. This was done for all combs per hive. Afterwards, the total values were calculated for each hive and assessment date.

Behaviour of the Bees

The behaviour of the bees on the crop and around the hive was assessed during the exposure period. The assessments were performed during the flight intensity assessments.

At least the following symptoms were checked in comparison to the control bees:

- Aggressiveness
- Intensive flying activity without landing on the crop
- Clustering at the bee hive entrance
- Landing on the covering net
- Intoxication symptoms

Recording of the Meteorological Data

For the entire exposure period the following climatic data were recorded by a weather station (non-GLP record, distance from the field site 3 km):

- air temperature (daily min/max)
- relative air humidity (daily min/max)
- rainfall

During applications and assessments, the following data were recorded at the field site (GLP record):

- cloud cover (estimated during application and assessments of flight intensity)
- air temperature, relative air humidity (only during the application)
- wind speed (only during the application)

Soil Sample for Residue Analysis

2 x 10 soil cores were taken on each of the with BYI 02960 SL 200G treated plots, after the 1st test item application and immediately after incorporation of the test item into the soil (i.e. before sowing *Phacelia tanacetifolia* seeds). Subsequent to the sampling, *Phacelia tanacetifolia* seeds were sown. Soil samples consisted of soil cores with a diameter of 50 mm that have been taken to a depth of 20 cm. The soil cores per individual plot (in total there were three BYI 02960 SL 200G treated plots) and sub-sample were pooled; 10 cores were used and pooled for residue analysis (i.e. sub-sample A) and

10 cores were used and pooled as a retained sample (sub-sample B). No soil samples were taken on the control and reference plots.

Collection of Flowers

On DAA0aa1 and DAA7, flowers of *Phacelia tanacetifolia* were collected. Samples from the control tunnels were taken first, followed by the samples from the test item tunnels. No samples were taken in the reference item tunnels.

The terminal inflorescences with open flowers was cut at the end of the stipe and bagged. A pooled sample comprising ≥ 10 g flowers per treatment was collected from at least 12 different locations across each tunnel. Each sample was divided into two sub-samples (A and B).

Collection of Pollen from Combs

On DAA 7 no pollen samples could be taken from the hives since no pollen was available. This can be explained by the restricted foraging area during the confinement in the tunnel tents (DAA-4 to7), which did not allow for the storage of excess *Phacelia*-pollen, concurrently to the on-going feeding of the brood.

Collection of Nectar from Combs

One nectar sample per tunnel (excluding the reference item tunnel) was taken from the hives on DAA7. Samples from the control tunnels were taken before those of the test item tunnels.

The nectar was collected by means of a table spoon which was pushed into the wax covered nectar cells. Each sample was divided into two sub-samples in order to get one A (residue analysis) and one B sample (retained).

Collection of Wax from Combs

One bee wax sample per tunnel (excluding the reference item tunnel) was taken from the hives once on DAA7. Samples from the control tunnels were taken before those of the test item tunnels. Knifes were used for sampling. Each sample was divided into two sub-samples in order to get one A (residue analysis) and one B sample (retained).

Residue analysis in honeybee products and flowers

Residue levels of BYI02960 and its metabolite BYI02960-difluoroethylaminofuranone (BYI02960-DFEAF) in pollen, nectar and beewax from comb as well as in flowers of *Phacelia tanacetifolia*. In addition, also the soil concentration of BYI02960 after application and immediate soil in corporation on the test plot of the test item treatment group has been determined.

Calculations and statistical analysis

For the evaluation of the number of dead bees, quotients of mortality (Q_M) were included. The formulas which were used for the calculation of the quotients are as follows:

QM = post-application mortality (DAA0aa to 7) ÷ pre-(3rd)-application mortality (DAA-4 to 0ba; per replicate)

QM(0aa) = mortality on the day of 3rd application (DAA0aa) ± pre-(3rd)-application mortality (DAA-4 to 0ba; per treatment group)

QM(mean) = post-application mortality (DAA0aa to 7) ± pre-(3rd)-application mortality (DAA-4 to 0ba; per treatment group).

The data of mortality and flight intensity of the test item and the reference item group were compared to the control in two separate approaches. The data were tested for normality and homoscedasticity using Shapiro-Wilk test ($p > 0.05$) and folded F-test ($p > 0.05$), respectively. Data were statistically compared using t-test (method pooled, $p \leq 0.5$) in case of normality and homoscedasticity. In case of no homoscedasticity but proven normality t-test was conducted with method Satterthwaite (same as Welch's t-test, $p \leq 0.5$). In case of no normality and no homoscedasticity Wilcoxon test ($p \leq 0.5$) was used

Results

Climatic conditions

Temperature during 3rd application was between 16.0 and 30.7.°C, 42-93% RH, no rainfall;
Temperature during observation ranged from 16.0 to 33.1 °C. No rainfall.

Mortality

Mortality of the different test groups is ported in the following figure (copied from the report).

Figure 9.4.2-25. Mean number of dead bees (worker bees, larvae and pupae)/treatment group/day counted in the dead bee traps and on the linen sheets prior to and after the 3rd test item application.

* = statistically significant (lower);

0ba = day of application;

0aa = after 3rd test application in T and the concurrent applications in C and R, respectively.

No statistically significant differences between the daily mortality values in the control and the test item treatment group were detected throughout the entire assessment period. The high number of dead bees in R during the post application period shows the sensitivity of the test system and was statistically significantly increased from DAA0aa to DAA3.

EFSA asked RMS to provide more detailed data for adult mortality. The mortality data for dead bees for the individual hives are copied below from the study report (Tables 14, 15 and 16). The study report does not provide separate data for adults and pupae.

Flight intensity

Figure 9.4.2-26 presents the mean flight intensity in the treatments groups C, T and R. On the day of the 3rd application (DAA0aa) until DAA7 reductions in flight intensity were found in the test item group T when compared to the control group (T). On DAA0aa and DAA5, the flight intensity was statistically significantly lower in T when compared to C.

Figure 9.4.2-26. Mean number of forager bees/m2 inside the tunnels for C (control), T (treatment) and R (reference) prior to and after the 3rd application in T.

* = statistically significant (lower);

0ba = day of application;

0aa = after 3rd test application in T and the concurrent applications in C and R, respectively.

Strength of the colonies

Results concerning the strength of the colonies are reported in the following figures. Figures were compiled with data from the original tables from the report.

Number of bees

The 1st and 2nd colony assessment were made during confined tunnel situation. Increases in colony strength were observed at the 3rd colony assessment. According to the author, the observed decrease in the average number of bees in T during the confined exposure conditions can be explained by limited forage. The limited forage was, on the other hand, sufficient for the smaller colonies in C (Individual colonies with less than 9000 bees were able to grow under confined tunnel situation (2C: 7130 to 8970 bees; 1T: 7130 to 8280 bees). These smaller colonies showed an increase of colony strength at the 2nd colony assessment.

Development of colony strength up to the last colony assessment was comparable between C and T. No test-item related adverse effect on colony strength were observed.

When comparing the mean mortality before application (DAA-4 to DAA0ba) to the day of application, Q_M(0aa) values were calculated to be 0.3, 0.8 and 11.4 for the treatment groups C, T and R, respectively. The Q_M(mean) values were calculated to be 1.0 for C, 1.3 for T and 3.2 for R,

respectively. The high mean number of dead bees in R during the post application period shows the sensitivity of the test system and was statistically significantly increased from DAA0aa to DAA3.

Figure 9.4.2-27. Mean number of bees in the treatment groups C, T and R at 5 colony assessment dates. Figure compiled by RMS from three tables in the report.

Abundance of brood and food stores

A decrease of abundance of brood (eggs, larvae and pupae) was observed in all treatments during confinement at the second assessment date (see figure below). According to the author this decrease can be explained by the unfavourable weather conditions before hive set-up and by the confined conditions inside the tunnel. Increases of brood abundance were found in all three treatments at fourth and fifth assessment day.

Decreases of food stores were observed in food stores in both, treatment and control, during confinement. The period after confinement showed increases in food stores. According to the author the decreases can be explained by the limited foraging area. No test item related adverse effects on the development of the food storage area were observed.

Figure 9.4.2-28. Mean number of brood and food cells in the treatment groups C, T and R at 5 colony assessment dates. Figure compiled by RMS from three tables in the report.

EFSA asked RMS to provide more detailed data on the adult and brood abundance.

The colony assessment data for the individual hives are shown below, in tables copied from the study report (Tables 20, 21 and 22).

STD = Standard deviation

Behaviour of the Bees

In the control group C, unusual behaviour was observed on the day of application approximately one hour after tap water treatment (approximately 100 bees sitting at the hive entrance, some cleaning, some shivering). On the following two days and on DAA5 and 6, clustering at the hive entrance was observed (alternately in 1C, 2C and 3C) and once aggressiveness at hive 1C.

In the test item treatment group T a repellent effect was observed. According to the author this repellent effect was only slight and was caused by an imbalance between an intensive flying activity and an infrequent landing on the crop (DAA0aa). Also clustering at the hive entrance was observed at hive 2T. On the following day, intensive flying over the crop coupled with an infrequent landing on the crop was still observed for colony 1T and 3T, clustering at the hive entrance at colony 2T and 3T. In the reference item treatment group R, clear symptoms of intoxication were observed on the day of application, after the treatment (2R); during the following days, clustering at the hive entrance (DAA1; 1R, 2R) and intensive flight activity coupled with a considerably reduced frequency of landing on the crop (DAA5; 1R) was described.

Since clustering at the hive entrance was observed in all treatment groups it did not happen in relation to the test item application.

Residue Analysis

Details on residue analysis are given in the table below.

Table 9.4.2-10. Residues of BYI02960 and BYI02960-difluoroethylaminofuranonein in samples of flower, nectar/honey, bee wax and soil, as obtained in the test item group.

Sample material	Test item	Sub-sample	Time of sampling	Residue [µg/kg]	
				BYI 02960	BYI 02960-DFEAF
Flower	BYI 02960 SL 200 G	A	0 DAA3	9533 – 20083	18 – 37
			7 DAA3	701 – 3590	9 – 35
Nectar (combs)	BYI 02960 SL 200 G	A	7 DAA3	LOQ – 2	<LOD – LOQ
Wax (combs)	BYI 02960 SL 200 G	A	7 DAA3	LOQ – 7*	LOQ*
Soil	BYI 02960 SL 200 G	A	0 DAA1	40 - 56	**

BYI 02960-DFEAF = BYI 02960-difluoroethylaminofuranone (BCS-CC98193)
DAA3 = Days after the 3rd test item application in the test item group and the corresponding tap water application in the control group
DAA1 = Days after the 1st test item application on bare soil, followed by immediate soil incorporation and sowing of *Phacelia tanacetifolia*-seeds
LOQ = Limit of Quantitation = 1 µg/kg in flower, nectar and bee wax (BYI 02960 and BYI 02960-DFEAF); = 5 µg/kg in soil (BYI 02960 and BYI 02960-DFEAF)
LOD = Limit of Detection = 0.1 µg/kg in flower, nectar and bee wax (BYI 02960 and BYI 02960-DFEAF); = 1.5 µg/kg in soil (BYI 02960 and BYI 02960-DFEAF)
* Cross-contminated with adherent/integrated remnants of other comb matrices (e.g. pollen, larval cocoon material, etc.)
** An analysis of BYI 02960-DFEAF in soil was not conducted

Conclusions of the author

The application scenario used in this study did not cause treatment-related adverse effects on mortality, brood and food development as well as on colony vitality. A slight repellent effect of the test item was observed on the day of the 3rd test item application, after the treatment.

Remarks by RMS

A positive control was included in the test and showed that the test system was behaving as expected. According to the EFSA Opinion on the Science behind the development of a risk assessment of plant protection products for bees (EFSA Journal 2012, 10: 2668, section 3.5.1), the main exposure route for bee brood is via pollen. Since *Phacelia tanacetifolia* is a major source of pollen, and pollen from uncontaminated sources was not present in the tunnels, the present test is suitable to show potential effect of flupyradifurone on brood related parameters, mortality and flight intensity.

The results of the study show that there is no adverse effect on mortality, on brood and food development as well as on colony vitality of the honeybees after foraging on *Phacelia tanacetifolia* after 3 test item applications. Several significant effects were present on flight intensity between

DAA0aa and DAA5. Mortality was not clearly higher in the treatment than in the control. A relation between decrease of flight intensity and mortality outside the hive may exist. When fewer bees are actively foraging the percentage of mortalities outside the hive may also decrease. From the results of the study it can be concluded that one soil application with 300 g as/ha and two foliar applications with 200 g as/ha have no effect on mortality, brood-, food-, and population development as well as on overall hive vitality. There are effects on flight intensity and behaviour. The results of this study, including the residue measurements, can be used for risk assessment.

Expert discussion in Pesticide Peer Review meeting 124 (December 2014):
(Please note that the word 'effect' in the text below might be interpreted as different from the control (i.e. may or may not include effects from the treatment), pending on the context.)

Some effects on forager mortality could not be excluded. Furthermore, at the second assessment there were virtually no larvae in T2 (T2 = assessment day 2). This may have been related to the shortage of pollen or test item related. It was noted that the larvae in the control also decreased indicating something affecting the colonies. However, the test item decreased to a greater extent. Due to the decreasing control it is difficult to be able to detect test-item related effects. It was considered that these types of effects were worth noting and then can be considered as a whole taking account the entire data set. The RMS noted that when they state that write that the numbers in the control and the test item were similar they mean the values were comparable (but not necessarily equal). Other experts consider that it is more useful for evaluation if it is stated that there is a difference and then the difference is not an issue. This is a minor point but helps when considering the data set as a whole i.e. looking for trends within the available data. In this case the experts agreed with the conclusion of the RMS.

There was statistical analysis of the forager mortality performed and some statistical effects on the treatment groups were observed. The RMS noted that it is difficult to interpret results by comparison of numbers without taking account of the statistical analysis.

Overall, the experts agreed with the RMS's assessment that the very slight increase on forager mortality were likely not due to the test item. This was because the level of effect was very slight and not statistically significant.

		(2007)			*tanacetifolia*, 2x foliar spray: 1st application 5 d before hive set-up and 2nd application 5 d after set-up during flowering and active foraging of bees
test substance	:	BYI 02960 SL 200 G, Batch no. 2010-007173.	acceptability	:	Acceptable
a.s. content	:	198.6 g flupyradifurone /L	Result	:	No adverse effect on mortality and brood development. Adverse effect on flight intensity and behaviour.

Description

The study was conducted in Pinache, federal state of Baden-Württemberg, Germany on a field of flowering *Phacelia tanacetifolia*. The experimental design of this study comprised three experimental groups with three replicates each, 9 tunnel tents were set-up before moving the hives to the experimental field. The individual treatment groups, the respective application rates per ha and the respective spray volumes per ha are described in the following table (copied from the report).

Table 9.4.2-11. Treatment groups, application rates and spray volume.

Treatment Group	Code	Time of application	Target application rate [g a.s./ha]*	Target application rate [g product/ha]	Spray Volume
Control (tap water)	C	DAA0, BBCH 63-65	None	None	400 L/ha
Test item (BYI 02960 SL 200 G)	T	DAA-10, BBCH 59-61	200	1 L	200 L/ha
		DAA0, BBCH 63-65	200	1 L	200 L/ha
Reference item (Insegar® 25 WG)	R	DAA0, BBCH 63-65	150	600 g	400 L/ha

DAA = days after 2nd test item application
* calculation based on the nominal content of a. s.

Reference item is Insegar (a.s. fenoxycarb). For the test, small healthy colonies with ten combs were used. The colony size at set-up was in the range 5313 – 8750 bees. The bee colonies were obtained from two beekeepers but were distributed
equally among the replicates in order to guarantee uniform bee material in all treatments. Furthermore the following criteria for each colony were guaranteed:

- 5 – 7 brood combs containing eggs, larvae and capped cells;
- 7 – 10 combs containing honey and pollen;
- bees are free of Nosema and Varroa disease symptoms and other bee diseases

The area covered per tunnel tent was 80 m². The bee colonies (one small bee colony per tunnel) were installed in the tunnel tents 5 days before the 2nd test item application and the concurrent application

in C and R, respectively, at early flowering of the crop. The colonies remained in the tunnels for 12 days. After the last assessment of mortality, foraging activity and behaviour during the confined exposure period on DAA7, the colonies were re-located from the tunnels and installed at a remote monitoring location for further observation. Colonies from the control, test item treatment and reference item treatment groups were installed at the same monitoring location. The test item solution was prepared shortly before each application. The applications were carried out with a portable boom sprayer that simulates a commercial application. The following conditions were met for both applications:

- crop at start of flowering (BBCH 59-61, closed flower buds) at 1st application in T
- crop at full flowering (BBCH 63-65) at 2nd application in T and the concurrent applications in C and R, respectively
- bees were actively foraging (≥ 5 bees/m²) at 2nd application in T and the concurrent applications in C and R, respectively
- wind speed was 0 m/s at 1st application in T, wind speed inside the tunnel tent was less than 2 m/s at the 2nd
- application in T and the concurrent applications in C and R, respectively
- air temperature did not exceed 30°C (both application times)
- there was no rainfall within at least two hours after the applications

During the 2nd test item application inside the tunnels, as well as during the concurrent application of tap water and the reference item, the bee colonies were covered with plastic sheets.

Mortality

Mortality was recorded in the crop. At each assessment, the dead bees found on the sheets and in the bee traps were counted and removed. Dead bees were differentiated between adult worker bees, males (drones), freshly emerged bees, pupae and larvae during each assessment.

The mortality of honeybees of the different treatment groups in the dead bee trap at the entrance of the hive and on the linen sheets were assessed prior to the 2nd test item application (DAA -4 to -1), on the day of the 2nd test item application (before and after the application: 0ba and 0aa, 1h, 2h, 4h and 6h after application) and after the 2nd test item application inside the tunnels (DAA 1 to 7) and on the monitoring site on DAA8 to 27.

Flight Intensity and behaviour

At each assessment, the number of bees that were both foraging on the flowers and flying over the crop were counted for 15 seconds. During the assessments of flight intensity, also the behaviour of the honeybees in the crop and around the hive were observed. with respect to at least the following criteria:

- aggressiveness towards the observer,
- guard bees attacking and/or preventing returning bees from entering the hive,
- intensive flying activity in front of the hives without entering the hive,
- intoxication symptoms (e.g. cramping, locomotion problems),
- clustering of large numbers of bees at the hive entrance

Condition of the colonies, development of the bee brood.

Development of Honey Bee Brood in Individual Cells

The development of the bee brood was assessed in individually marked cells. The development of each individually marked cell was determined throughout the duration of the study (the pre-imaginal development period of worker honeybees typically averages 21 days).

Condition of the Colonies

The condition of all colonies was checked during the experimental phase and the following parameters were assessed:

- Colony strength (number of bees
- Presence of a healthy queen (e.g. presence of eggs)
- Pollen storage area and area with nectar or honey
- Area containing cells with eggs, larvae and capped cells

Assessments of the colony condition were made once before placing the hives in the tunnels, once before the applications during full flowering and honeybees actively foraging on the crop, followed by five further colony assessments.

Recording of the Meteorological Data

For the entire exposure period and monitoring period, the following climatic data were recorded by an Eurofins Agroscience Services EcoChem GmbH weather station at a distance of approx. 5.66 km to the field site and approx. 5.95 km to the monitoring site (non-GLP record):

- air temperature (daily min/max)
- relative air humidity (daily min/max)
- daily precipitation

Additionally, precipitation during the exposure period was recorded by a rain gauge placed inside one the tunnel tents (GLP record). During applications and assessments, the following data were recorded at the field site (GLP record):

- cloud cover (estimated during application and assessments of flight intensity)
- air temperature, relative air humidity (only during the application)
- wind speed (only during the application)

Collection of samples

Samples of pollen, nectar/honey and wax were taken from different locations of the hives in the test item treatment group at the end of the study (DAA27).

Calculations and Statistical analysis

For the evaluation of the number of dead bees, quotients of mortality (Q_M) were included. The formulas which were used for the calculation of the quotients are as follows:

QM(DAA0aa) = mortality on the day of application (0aa) ÷ pre-(2nd)-application mortality (Q_{Mb}) (per treatment group).

QM(DAA0aa to 7) = post-application mortality exposure period ± pre-(2nd)-application mortality (Q_{Mb}) (per treatment group).

In addition, the author has calculated brood indices, compensation indices and termination rates (see following three figures). The indices and rates are calculated for several 'Brood Area Fixing Days' (BFD). At these days specific areas on the combs were evaluated for specific stages using a digital camera.

The data of mortality and flight intensity of the test item and the reference item group were compared to the control in a separate approach but in the same way. The data were tested for normality and homoscedasticity using Shapiro-Wilk test ($p > 0.05$) and folded F-test ($p > 0.05$), respectively. Data were statistically compared using t-test (method pooled, $p \leq 0.5$) in case of normality and homoscedasticity. In case of no homoscedasticity but proven normality t-test was conducted with method Satterthwaite (same as Welch's t-test, $p \leq 0.5$). In case of no normality and no homoscedasticity Wilcoxon test ($p \leq 0.5$) was used. Log-transformation was conducted if necessary to achieve better normality and homoscedasticity of data.

Results

Climatic conditions

Temperature during 2nd application was between 10.0 and 19.9.°C, 37.7-76.3% RH, no rainfall; Temperature during observation ranged from 8.6 to 27.8 °C. Rainfall from DAA19 between 0.2 and 33.3 mm per day.

<u>Mortality</u>

Mortality and flight intensity of the different test groups are reported in the following figures (copied from the report). Only on two single days, DAA9 and DAA21, the mortality of the test item treatment was statistically significantly higher compared to the control.

When comparing the mean mortality before application (DAA-4 to DAA0ba) until the day of the 2nd test item application, the QM(DAA0aa) values were calculated to be 0.9, 1.1 and 0.5 for the treatment groups C, T and R, respectively. The QM(DAA0aa to 7) values were calculated to be 1.4, 1.0 and 1.0 for C, T and R, respectively.

Figure 9.4.2-29. Mean number of dead bees/replicate/day counted in the dead bee traps and on the linen sheets inside the tunnels of the control group C, the test item group T and the reference group R prior to and after the 2nd application in T and the concurrent applications in C and R, respectively

0ba = day of application, before application

0aa = 2nd application in T and the concurrent applications in C and R, respectively

* statistically significantly higher than in the control group

Figure 9.4.2-29 shows the dead bees on the linen sheets and in the bee traps combined. EFSA asked RMS to provide more detailed data for adult and larvae/pupa mortality separately, so that it can be seen if the contribution of pupae mortality was negligible throughout the study.

Even though the report methods state that the dead bees found on the sheets and in the bee traps were differentiated between adult worker bees, males (drones), freshly emerged bees, pupae and larvae during each assessment, the results are only presented as total dead bees. However, numbers of dead bees found on the linen sheet and in the bee traps separately are available, for all replicates, treatments and assessment dates. They are shown below in Tables 18, 19 and 20, which are copied from the study report. Based on these tables, the following overview of numbers of dead bees on the linen sheets (LS) and in the dead bee traps (BT) in the three treatment groups in the different test periods can be made (numbers are the mean from three hives):

	C		T		R	
DAA	LS	BT	LS	BT	LS	BT
-4 to 0ba	40.3	10.2	74.5	12.3	69.5	24.2
0aa	34.7	11.7	74.7	16.7	31.7	12.0
0aa to 7	36.0	35.1	52.5	38.5	46.7	49.8

The relative amount of dead bees in the dead bee traps (which will contain dead pupae) is higher in the control than in the treatment group. Thus, there is no indication that the pupae mortality is higher in the treatment group than in the control.

$Q_{M(DAA0aa\ to\ 7)}$ = ∅ post-application mortality exposure period ÷ ∅ pre-application mortality (per treatment group and replicate)

Figure 9.4.2-30. Mean number of forager bees /m2 inside tunnels prior to and after the 2nd application in T and the concurrent application in C and R, respectively.

0ba = day of application, before application;

0aa = 2nd application in T and the concurrent applications in C and R, resp.

* statistically significantly lower than control group

X = no flight activity in any of the treatments due to adverse weather conditions

Significant effects on flight activity on the day of the 2nd test item application as well as on some further days during the confined exposure period were present.

<u>Strength of the colonies</u>

Mean numbers of bees are given in the figure below.

Figure 9.4.2-31. Strength of the colonies (mean number of the honeybees per hive) in the treatment groups C, T and R.

The development of colony strength was comparable between C and T throughout the study period and showed the fluctuations which are typical of this endpoint. As such, no test-item related adverse effects on colony strength were observed.

<u>Development of Brood</u>

Figure 9.4.2-32. Mean number of brood and food cells in the treatment groups C, T and R.

Development of brood

The mean abundance of brood (sum of cells containing eggs, larvae, and pupae) assessed before set-up of the hives (first colony assessment, DAA-7/-5) was comparable in all treatment groups with 20400 cells/hive for C,19667 cells/hive for T and 19600 cells/hive for R. At the second colony assessment (DAA-1), the mean abundance of brood in C, T and R had decreased slightly (19267 cells/hive for C, 17867 cells/hive for T and 19533 cells/hive for R). At the third colony assessment, during the confined exposure period, on DAA4, the mean abundance of brood in C and T was on an almost identical level (C: 17533 cells/hive, T: 17933 cells/hive), whereas the mean abundance of brood in R decreased strongly to 13400 cells/hive. On the fifth colony assessment (DAA14), no appreciable changes were observed in the mean abundance of brood in C and T, whereas a strong decrease in R to 8333 cells/hive occurred. This refers to a clearly detectable effect of the reference item, which is typical for this point in time. Brood of all stages (eggs, larvae, capped brood) was present in all colonies at all assessments during the study, with the exception of colony T1, which was found queenless from the fourth to the last colony assessment. The number of brood cells consequently decreased from this time on (fifth - seventh colony assessment) in colony T1 and as such, from the fifth colony assessment onwards, also the mean values in T were lower than in C (sixth colony assessment, DAA21: 20200 cells/hive for C, 13667 cells/hive for T, seventh colony assessment, DAA27: 18600 cells/hive for C, 12667 cells/hive for T). Except for the colony T1, the fluctuations of all brood stages were within the range of natural variation and typical for this kind of study. Overall, honey bee brood development and colony conditions in test item treatment T were comparable to control treatment during the whole assessment period. No test-item related adverse effects on brood development were observed.

Development of the Food Storage Area

The mean extent of food stores in the colonies (sum of cells containing nectar and pollen) assessed before set-up of the hives (first colony assessment, DAA-5) was 14067 cells/hive for C, 17333 cells/hive for T and 14600 cells/hive for R. At the second colony assessment (DAA-1), the mean extent of food stores decrease slightly in C and increased slightly in T and R (C: 13067 cells/hive, T: 17600 cells/hive, R: 15733 cells/hive). At the third colony assessment, during the confined exposure period, on DAA4, the mean extent of food stores in the colonies C, T and R had decreased (C: 9067 cells/hive, T: 16333 cells/hive, R: 11933 cells/hive). At the two subsequent assessments on the remote monitoring location at DAA10 and DAA14 (fourth and fifth colony assessment), the mean extent of food stores in C and T had decreased in parallel, increased thereafter in parallel on DAA21 and decreased again in parallel to 4400 cells/hive in C and 5133 cells/hive in T at DAA27. The mean extent of food stores in the R hives from DAA10 to DAA27 was an alternate de- and increase with 6133 cells/hive on the last colony assessment.

The observed parallel decrease in food stores in both, treatment and control, during confinement as well as the subsequent alternate, but again parallel de- and increase in C and T, respectively, can be

considered as typical for this type of study. No test-item related adverse effects on the development of the food storage area were observed.

Brood and compensations indices and termation rates are given in the three figures below. These calculations show that the control and treatment are very similar.

Figure 9.4.2-33. Course of the brood index in the treatment groups C, T and R.

Figure 9.4.2-34. Course of the compensation index in the treatment groups C, T and R.

Figure 9.4.2-35. Termination rates at the last assessment (BFD22) in the treatment groups C, T and R.

Behaviour of the Bees

No abnormal behaviour was recorded in the control, in the test item and in the reference item treatment before the 2nd test item application and the concurrent application in C and R, respectively (DAA-4 to DAA0ba). In the test item treatment T after the 2nd test item application on DAA0aa, a few bees were observed with intoxication symptoms (cramping, locomotion problems, coordination problems), moreover, an intensive flying over the crop coupled with an infrequent landing on the crop could be observed together with a slight repellent effect. On the following days (DAA1 to 7), normal behaviour was observed in all three tunnels of the test item treatment. In the reference item treatment R, after application on DAA0aa, a strong repellent effect (no or low flight activity on the crop) as well as several bees with obvious signs of intoxication were observed. In the control group, normal behaviour was recorded throughout the observation period except for the evening of DAA0aa, were about 200 to 500 bees were observed motionless on the covering net in C3 as well as in T1 - T3, respectively. In the test item treatment group, during the last assessment in the evening of DAA0aa(+6h), no bees were found motionless on the covering net any more. Except for DAA0aa, honey bee behaviour in test item treatment T was comparable to the control treatment throughout the entire assessment period.

Residue analysis

A summary of the analytical results, as obtained by analysing samples of pollen, nectar/honey and bee wax, collected from the bee hives of the test item group at the end of the study (27 days after the last test item application), is reported in the following table.

Table 9.4.2-12. Residues of BYI 02960 and BYI 02960-difluoroethylaminofluranone in samples of pollen, nectar/honey and bee wax, as obtained in the test item group

Sample	Test Item	Residue [µg/kg]	
		BYI 02960	BYI 02960-DFEAF
Pollen	BYI 02960 SL 200 G	2 - 4	< LOQ
Nectar/Honey	BYI 02960 SL 200 G	< LOQ - 17	< LOQ - 1
Bee wax	BYI 02960 SL 200 G	1 - 62	< LOQ

BYI 02960-DFEAF = BYI 02960-difluoroethylaminofluranone (BCS-CC98193),
LOQ = Limit of Quantitation = 1 µg/kg in nectar, pollen and bee wax, respectively (BYI 02960 and BYI 02960-DFEAF)

Conclusions of the author:

A pre-flowering foliar application of the test item, corresponding to 200 g BYI 02960 as/ha to a highly bee-attractive crop (*Phacelia tanacetifolia*), was followed by a further foliar application of the test item, again corresponding to 200 g BYI 02960 as/ha, during full-flowering with honeybees actively foraging on the crop.

This application scenario did not cause treatment-related adverse effects on mortality, on flight intensity, on honeybee behaviour, on brood- and food development as well as on colony vitality under forced exposure conditions. A slight repellent effect of the test item was indicated by a reduced flight intensity on the day of the 2nd test item application as well as on some further days during the confined exposure period.

Remarks by RMS

A positive control was included in the test and showed that the test system was behaving as expected. According to the EFSA Opinion on the Science behind the development of a risk assessment of plant protection products for bees (EFSA Journal 2012, 10: 2668, section 3.5.1), the main exposure route for bee brood is via pollen. Since *Phacelia tanacetifolia* is a major source of pollen, and pollen from uncontaminated sources was not present in the tunnels, the present test is suitable to show potential effect of flupyradifurone on brood related parameters, mortality and flight intensity.

A reduced flight intensity on the day of the second application and on DAA0aa, 4, 6 and during DAA0aa to DAA7 (mean) the two following days. A relation between decrease of flight intensity and mortality outside the hive may exist. When fewer bees are actively foraging the percentage of mortalities outside the hive may also decrease. Behavioural effects were observed at the day of second application (intoxication symptoms and coordination problems). From the results of the study it can be concluded that two foliar applications on *Phacelia tanacetifolia* sprayed once with BYI 02960 pre-flowering and once full-flowering at an application rate corresponding to 200 g as/ha have no effect on mortality, brood-, food-, and population development as well as on overall hive vitality. There are effects on flight intensity and behaviour. The results of the study, including the residue measurements, can be used in the risk assessment.

Expert discussion in Pesticide Peer Review meeting 124 (December 2014):

(Please note that the word 'effect' in the text below might be interpreted as different from the control (i.e. may or may not include effects from the treatment), pending on the context.)

The RMS considered that this study resulted in the greatest level of exposure. The experts noted that there was a clear indication of a potential, slight effect due to the test item. Some indications of sublethal intoxication were noted. The flower visits were also lower for the test item. These effects were noted by the RMS.

Statistical analysis on forager mortality was performed. A statistically significant effect was only observed on a few times points. The level of mortality was not consistently statistically significant compared to the control. The experts noted that there was an application prior to the introduction of the hives. Therefore, it is not possible to compare with pre-application data.

The pooling of the dead adult bees and pupae was discussed. Ideally the data would be presented separately.

There was no agreement on whether this study indicates a slight test item related effect under the exposure conditions in the study. This differs to the RMS who believes that the study indicates no clear effect on forager mortality. The majority of the experts agreed with the assessment of the RMS and did not consider that the results indicated a clear effect on mortality.

Study IIA 8.16.2/08

Characteristics

Reference	:	Rexer 2013	nominal dose	:	2x 200 g a.s./ha, 10 d interval
Type of study	:	Residues in nectar and honey under semi-field conditions in *Phacelia tanacetifolia*	species	:	Honey bee (*Apis mellifera*)
Year of execution	:	2012	exposure duration	:	14 d
GLP statement	:	yes	dosing method	:	Tunnel test in *Phacelia tanacetifolia*, 2x foliar spray: 1st application before onset of flowering and 2nd application during flowering
Guideline	:	OEPP/EPPO guideline No. 170 (4), 2010, SANCO/3029/99 rev. 4.	Acceptability	:	Acceptable
Test substance	:	BYI 02960 FS 200 G, Batch no. 2011-002192	Results	:	Residue levels in pollen and nectar were determined, see below
a.s. content	:	201.4 g flupyradifurone /L			

Description

Residues of BYI 02960 in Phacelia nectar and Phacelia pollen after two spray applications of BYI 02960 SL 200 to flowering Phacelia tanacetifolia. Nectar and pollen was collected from forager bees and combs.

Location

Field experiment was conducted from July 2012 to August 2012 in Niefern-Öschelbronn, federal state of Baden-Württemberg, Germany.

Sizes field and crop, test condition (tunnel or field)

The size of each field crop (each replicate) was 70.4 m2 (test item treatments and control plots). Fields were separated by 7.0 km. The crop was Phacelia tanacetifolia. Previous crop was maize. Three herbicides, nicosulfuron, prosulfuron and mesotrione were in the early spring (April, 27, 2011), before sowing of Phacelia.

Active substance

BYI 02960 SL 200 G; Specification No.: 102000021884 - 02; Material No.: 79718845; Batch-ID: 2011-002192; content: BYI 02960: 201.4 g/L (content of as analysed).

Treatments

Three treatment groups (see Table below):

- T1 (BYI 02960; for sampling of forager bees; three replicates), application before the onset of flowering (BBCH 58-60).
- T2 (BYI 02960; for sampling of nectar and pollen from combs; three replicates), application during full flowering (BBCH 65) and
- an untreated control C (one replicate).

Table 9.4.2-13 Application schedule

Trial S12-00038-01					
Appl' Code	Plot	Timing	Application Rate (priority to active ingredient)		Water Volume
-	C	-	-	-	-
A1	T1a-T1c, T2a-T2c	BBCH 58-60 (= 0DAA1)	993 mL product/ha [1)]	200 g a.i./ha	200 L/ha
A2	T1a-T1c, T2a-T2c	BBCH 64-65 (= 0DAA2)	993 mL product/ha [1)]	200 g a.i./ha	200 L/ha

[1)] based on analysed content of a.i.

Test concentrations

Two applications with BYI 02960 SL 200 G at a target rate of 200 g as/ha respectively. The first test item application was performed on 24 Jul 2012, 10 days before the second test item application

(10DBA2) and 7 days before set-up of the hives in the tunnels. Applications were performed in 200 L water/ha.

Species tested

Honey bees of the race *Apis mellifera*.

Population size

For the test, healthy colonies and queen-right with twenty combs containing approx. 13,000 bees in the control (1 hive), 15,500 to 28,000 bees in treatment group T1 (3 hives. Replicate T1c had 30 combs and therefore high numbers of bees (28,000). Treatment group T2 (3 hives) had 15,500 to 27,000 bees.

Timing placement hives under test conditions

The set-up of the colonies in the tunnels was performed at BBCH 63 (beginning of flowering) on 31 July 2012 (3DBA2). Three days after set-up of the colonies, the 2nd test item application was performed on 3 August 2012 (0DAA2) during full flowering (BBCH 65) and during honeybee foraging activity. One commercial honey bee colony was used per tunnel. Tunnel measured 5 x 16 m.
At the end of the confined exposure phase on 13 August 2012 (10DAA2; BBCH 67-69), the honeybee colonies were relocated to a monitoring site at a distance of approximately 0.69 km to the field site with the tunnels. The area around the monitoring site was without flowering main crops attractive to bees. Hives were placed at the monitoring site from 14 August 2012 to 31 August 2012.

Parameters observed and timing thereof

The following parameters were observed during the exposure phase:
1. Colony assessment: Four days before the 2nd test item application (4DBA2), a colony assessment was performed in all treatment groups (C, T1 and T2) which included an assessment of the colony strength as well as the brood and food status.
2. Samplings of pollen and nectar from forager bees: Sampling in T1 and C started one day before the 2nd test item application (1DBA2). Thereafter, forager bee samplings inside the tunnels were performed daily in T1 up to 10DAA2 (3 times on 0DAA2, once per day from 1DAA2 to 10DAA2) and four times in C (0DAA2, 1DAA2, 4DAA2, 7DAA2). Bees were frozen, pollen loads were collected with tweezers and honey bulbs were removed. All material was kept frozen until analysis.
3. Phacelia nectar and pollen from combs in T2 were sampled once per day from 0DAA2 to 10DAA2 inside the tunnels and on 4 occasions from 12DAA2 to 28DAA2 at the monitoring site.

Residue analysis

Pollen (sampled from combs or prepared from forager bees) and nectar (sampled from combs or prepared from forager bees) samples were analysed for residues of BYI 02960 and its metabolite BYI 02960-DFEAF (BYI 02960-difluoroethylaminofuranone). Residue analysis was performed by using high Performance Liquid Chromotography (HPLC) coupled with electrospray and tandem mass spectrometry (MS/MS) detection. Analysis of nectar and pollen followed the provisions of method 01206/M001.

Statistical evaluation

Not performed.

Results

Actually applied concentrations

Actually applied spray applications in the three replicates of T1 were between 198.9 and 203.1 g as/ha in the first spray (deviation of -0.57 to +1.56%) and between 209.5 and 211.6 g as/ha in the second spray (deviation of +4.76 to + 5.82%).

Actually applied spray applications in the three replicates of T2 were between 198.2 and 201.0 g as/ha in the first spray (deviation of -0.92 to +0.50%) and between 205 and 210 g as/ha in the second spray (deviation of +2.27 to + 5.11%).

Climatic conditions

Temperatures, humidity and precipitation were recorded at the field site during the exposure phase and at the nearest official weather station at Niefern, 0.91 km away from the monitoring site during the post exposure period. No abnormal weather data were obtained.

Residue analysis

Method validation: Mean recovery of BYI 02960 in pollen and nectar/honey were 98 and 89% resp. with corresponding relative standard deviations of 8.8 and 4.4%, resp. Mean recovery of BYI 02960-DFEAF in pollen and nectar/honey were 85 and 84%, resp., with corresponding relative standard deviations of 7.9 and 7.9%, resp. For both parent and metabolite LOQ was 1 µg/kg and LOD was 0.1 µg/kg for both pollen sampled from forager bees as from nectar/honey from combs.

In the control, no residues were detected in nectar sampled from forager bees. All residues were <LOD.

Condition of the colonies

In the figure below the condition of the colonies is presented (graph prepared by evaluator) as was assessed four days before the second test item application, before set-up of the hives.

Figure 9.4.2-36 Condition of the colonies four days before 2nd application (prepared by evaluator)

Table 9.4.2-14 Residues of BYI02960 and BYI02960-difluoroethylaminofuranone (BYI02960-DFEAF) in samples forager bees and combs as obtained from the test item treatment groups

Sample	Test Item	Residue [µg/kg]	
		BYI 02960	BYI 02960-DFEAF
Pollen from comb	BYI 02960 SL 200 G	139 - 22529	1.6 - 46
Pollen from forager bees	BYI 02960 SL 200 G	138 - 70667	1.3 - 135
Nectar from combs	BYI 02960 SL 200 G	< LOQ - 186	< LOD - 9.4
Nectar from forager bees	BYI 02960 SL 200 G	4.8 - 3304	< LOQ - 122

BYI 02960-DFEAF = BYI 02960-difluoroethylaminofuranone (BCS-CC98193),
LOQ = Limit of Quantitation = 1 µg/kg in nectar and pollen, respectively (BYI 02960 and BYI 02960-DFEAF)
LOD = Limit of Detection = 0.1 µg/kg in nectar and pollen, respectively (BYI 02960 and BYI 02960-DFEAF)

The residue data as collected in pollen and nectar from forager bees and combs are shown in tables 9.4.2-14 (ranges) and -15 (in detail). Second test item application was performed at August 3. Colonies were placed in the tunnels at July 31, 3 days before the second application. First application had taken place 7 days before set up of the hives. First samplings were performed at August 2. Residues were present in all instances but were very low. At August 3, samplings for residues in pollen and nectar sampled from forager bees were performed at three time points (1 h, 2,5 h and 4 h after application).

Conclusions of the author

The distance between the field and the monitoring site was 0.69 km instead of the anticipated 3 km. The author states that this had no impact on the study as the crop area inside the tunnels remained confined until the end of flowering and was therefore not accessible from the outside. Relocation occurred at BBCH 69 (= End of flowering: fruit set visible) and foraging of re-located bees in treated Phacelia is therefore indeed not likely and evaluator agrees that shorter distance has no impact on the result.

Apart from a short summary and the results given in Table 9.4.2-14, no evaluation or discussion of the results was made by the author.

Remarks by evaluator

One of the colonies in test item group T1 had 30 combs in order to achieve the required colony strength. As this particular hive had very high numbers of bees (28,000) it is unclear why the control hive with very low number of bees (13,000) was found to be acceptable. The possible reason might be that the control hive is only used to confirm that no residues of flupyradifurone were present in the nectar and pollen. Development of the colonies was not the main issue in the study.

Residues in pollen and nectar from combs and pollen and nectar from forager bees should be measured not only in the treatments but also in the controls. Controls were only included in the experiment for pollen of the forager bees. The reason of omission of the other controls was not mentioned by the author. However, as no residues were found in the pollen of the control forager bees, absence of residues in nectar of the forager bees can be assumed, as fewer residues are present in nectar than in pollen. Moreover, if no residues are present in the pollen of the forager bees, no residues can be expected in the combs.

Table 9.4.2-14 and figures 9.4.2-37 to 9.4.2-40 show that fewer residues are present in the nectar than in the pollen. Also, much higher residue levels of both parent and metabolite (Figures not prepared for the metabolite) can be found in the pollen and nectar of the forager bees than in the combs. At the same time, the decline of concentrations in forager material is faster than in comb material. Figures 9.4.2-37 and -38 show that residues in the pollen and nectar collected by the foragers decrease to very low values within 3 days. Figures -39 and -40 show larger standard deviations than Figures -37 and -38. This can be explained by the fact that in Figures -37 and -38 the nectar and pollen was directly sampled from forager bees and during one sampling not much variation between residue levels of collected pollen and nectar of individual bees is expected. Residue levels in the nectar and pollen sampled from the combs, on the contrary, largely depend on the date of filling of the individual cells and the choice of the cells to be collected and the degradation rate of flupyradifurone. It is not described which cells were chosen for collection of the material and how to discriminate between recently filled cells (little degradation) and older cells (more degradation).
Following results can be used for risk assessment:

1. highest mean residue level (N=3)
   - in pollen from forager bees of 64,743 µg/kg (SD 5,109) at August 3 (= day of 2nd application)
   - in nectar from forager bees of 3,048 µg/kg (SD 264) at August 3 (= day of 2nd application)
   - in pollen from combs of 10,171 µg/kg (SD 11,226) at August 7 (= 4 days after 2nd application)
   - in nectar from combs of 127 µg/kg (SD 83) at August 5 (= 2 days after 2nd application)
2. residues in pollen and nectar collected by forager bees are much higher than residues in combs;
3. residues in pollen are higher than residues in nectar;
4. residues in pollen and nectar collected by forager bees decrease to very low values within a few days.
5. residues in the comb remain present for a longer time (24 days after 2nd application, residue level in pollen from combs is 1709 µg/kg and 32 µg/kg in nectar from combs).
6. condition of the colonies was similar for T1 and T2 colonies (Figure 2). Only one control replicate with a low number of bees (13,000) was used in the study. Normally this would be a problem. But since this study was not performed to monitor the effects of the pesticide this is not considered to be a problem. The control was only necessary to confirm that residues of pesticide were not present in pollen and nectar.

test substance	:	BYI 02960 SL 200 formulation Batch no: 2010-001187	LOQ	:	BYI 02960 : 0.01 mg/kg DFEAF : 0.01 mg/kg
Species	:		storage	:	≤ 255 d at -18°C
			Acceptability	:	Y
			Results	:	Residues in blossoms, nectar and pollen were determined, see below

Study design

A semi-field trial was conducted in North-Carolina (USA) to determine the residues of BYI 02960 and the metabolite difluoroethylamino furanone (DFEAF) in blossoms, nectar, and pollen collected from melon plants treated with flupyradifurone in a 200 g SL formulation.

The target applications of the formulation were two different regimes; The first as one drench application at a dose rate of 0.410 kg as/ha (treatment 1) and treatment 2 as two foliar treatments at a rate of 0.205 kg as/ha a spray interval of 7-10 days. No control plot was used. Samples were collected at intervals of 17, 19, 21, 23, 26, 28, 30, 32, and 34 days after the drench application in the T1 plots. Samples were collected at intervals of -1, +1, +3, and +5 DAA(B) and at intervals of -1, +1, +3, +5, and +7 DAA(C) in the T2 plots.

Four bee tunnels were erected (replicate tunnels for each treatment regimen) and one normally developed, apparently healthy and queen-right honey bee colony (*Apis mellifera* L. (Hymenoptera, Apidae) was placed in each tunnel four days prior to the first foliar application to the T2 plots (14 days following application to the T1 plots).

Forager bees were used to collect nectar (honey stomach) samples from all plots at intervals of +1DAA1, +3DAA1, +5DAA1, -1DAA2, +1DAA2, +3DAA2, and +7DAA2 in the foliar (T2) plots, corresponding to DAAs of 19, 21, 23, 26, 28, 30, and 34 days following the soil drench application in the T1 plots. The bees were aspirated into a box of dry ice as they returned to the colony and frozen until later dissection to obtain composite honey stomach samples.

Pollen, which was available in smaller quantities than anticipated, was collected from pollen traps affixed to the hive at +1DAA1, +3DAA1, and +5DAA1 and at +3DAA2 in the T2 plots. These corresponded to DAAs of 19, 21, 23, and 30 days following the soil drench application in the T1 plots. Additional pollen samples were obtained from the T1 plot forager bees (without honey stomachs) at the 23- and 28-day intervals by removal of pollen grains adhered to their legs with a tweezers.

The residues of BYI 02960 and DFEAF were quantified by high performance liquid chromatography/triple stage quadrupole mass spectrometry (LC/MS/MS) using stable isotopically labeled internal standards. The individual analyte residues (in parent equivalents) were summed to give a total BYI 02960 residue. The limit of quantitation was 0.010 ppm for each analyte and 0.020 ppm for the total BYI 02960 residue.

Results

Details of the trial are presented in table B.9.4.2-16.

Conclusion

In study RARVP019 an acceptable residue trial in melon matrices was performed to establish residues in pollen, honey stomachs and blossoms.

The study revealed that a drench application of BYI 02960 SL 200, corresponding to 400 g a.s/ha, to melon plants at a growth stage typical for early transplanting (BBCH 15), resulted in maximum BYI

02960 residue levels in melon blossoms, pollen, and honey stomachs of 0.363, 0.314 and 0.695 mg/kg, respectively. The corresponding maximum residue level in melon blossoms, pollen, and honey stomachs of the metabolite BYI 02960-DFEAF was determined to be 0.017, <0.010 and 0.060 mg/kg, respectively.

Two foliar applications of 200 g as/ha and 400 g as/ha at BBCH 69-70, resulted in maximum BYI

02960 residue levels in melon blossoms, pollen, and honey stomachs of 2.778, 1.441 and 0.339 mg/kg, respectively. The corresponding maximum residue level in melon blossoms, pollen, and honey stomachs of the metabolite BYI 02960-DFEAF was determined to be 0.025, 0.022, 0.029 mg/kg, respectively.

			Results	:	Residues in plants, flowers, nectar and pollen were determined, see below

Study design

A semi-field trial was conducted in Spain to determine the residues of BYI 02960 and the metabolite difluoroethylamino furanone (DFEAF) in plants, flowers, nectar, and pollen collected from watermelon plants treated with flupyradifurone in a 200 g SL formulation.

The target application rate was three sequential drench applications of 150 g as/ha with a seven-day spray interval at a water rate of 75 mL/plant. One control plot was used. Applications were made after transplanting (BBCH 12-13).

Commercial bee colonies were placed in the tunnels, just when enough flowers were present to allow foraging of the bees (BBCH 66), 28 days after the last application. Samples of young plants were taken at the time of transplanting from the greenhouse to the field (non-GLP). More plant samples were taken in regular intervals after the applications. Additionally, flowers as well as nectar and pollen from combs were collected at several dates, starting at the beginning of flowering and continuing during the flowering period of the crop for subsequent residue analysis.

Residue analysis was performed by using High Performance Liquid Chromatography (HPLC), coupled with electrospray and tandem mass spectrometry (MS/MS) detection, according to the provisions of method 01206/M001 (BYI 02960 and its relevant metabolite BYI 02960-difluoroethylaminofuranone). The Limit of Quantitation (LOQ) of BYI 02960 and BYI 02960-difluoroethylaminofuranone, defined as the lowest validated fortification level, was 1 µg/kg in green plant material, flower, nectar and pollen, respectively. The Limit of Detection (LOD) of BYI 02960 and BYI 02960-difluoroethylaminofuranone was 0.1 µg/kg in green plant material, flower, nectar and pollen, respectively.

All results of the method validation were in accordance with the general requirements for residue analytical methods; therefore, the method was validated successfully.

The residue levels of BYI 02960 and BYI 02960-difluoroethylaminofuranone (BYI02960-DFEAF) in samples of green plant material, flower, pollen and nectar, as obtained in the untreated control group, were always below LOQ.

Results

No rainfall was recorded on the days of application, except for 0.2 mm on the day of second application, which is considered irrelevant. Details of the trial are presented in table B.9.4.2-17.

Conclusion

The study revealed that three sequential drench applications of flupyradifurone at a 7 days interval, corresponding to 150 g a.s./ha, respectively, to watermelon plants, with the first treatment at a growth stage typical for early transplanting (BBCH 15), resulted in maximum BYI 02960 residue levels of 1.184 mg/kg in watermelon flowers, 6 µg/kg in watermelon pollen and ≤ 1 µg/kg in watermelon nectar. The corresponding maximum residue level of the metabolite BYI 02960-DFEAF in watermelon flowers was 6 µg/kg and <1 µg/kg in watermelon pollen and -nectar, respectively.

Study design

A semi-field trial was conducted in Spain to determine the residues of BYI 02960 and the metabolite difluoroethylamino furanone (DFEAF) in flowers and pollen collected from tomato plants treated with flupyradifurone in a 200 g SL formulation.

The target application rate was one drench applications of 200 g as/ha. One control plot was used. Applications were made after transplanting (BBCH 13-14).

Commercial bumble bee colonies were placed in the tunnels, as soon as enough flowers were present to allow foraging of the bees (BBCH 62-63), 41 days after the application.

Samples of soil characterisation were taken once. Samples of tomato flowers as well as tomato pollen collected by forager bumble bees were taken at several dates for subsequent BYI 02960-residue analysis, starting at the first day of exposure and continuing during flowering of the crop.

For determination of residues of BYI 02960 in pollen, pollen loads from forager bumble bees were sampled ten times during exposure of the bumble bees inside the respective tunnels.

Residue analysis was performed by using High Performance Liquid Chromatography (HPLC), coupled with electrospray and tandem mass spectrometry (MS/MS) detection, according to the provisions of method 01206/M001 (BYI 02960 and its relevant metabolite BYI 02960-difluoroethylaminofuranone). The Limit of Quantitation (LOQ) of BYI 02960 and BYI 02960-difluoroethylaminofuranone, defined as the lowest validated fortification level, was 1 µg/kg in flower and pollen,

respectively. The Limit of Detection (LOD) of BYI 02960 and BYI 02960-difluoroethylaminofuranone was 0.1 µg/kg in green plant material, flower, nectar and pollen, respectively.

All results of the method validation were in accordance with the general requirements for residue analytical methods; therefore, the method was validated successfully.

The residue levels of BYI 02960 and BYI 02960-difluoroethylaminofuranone (BYI02960-DFEAF) in samples of flower and nectar, as obtained in the untreated control group, were always below LOQ.

Results

Details of the trials are presented in table B.9.4.2-17.

Conclusion

The study revealed that a drench application of BYI 02960 SL 200, corresponding to 200 g a.s/ha, to tomato plants at a growth stage typical for early transplanting (BBCH 13-14), resulted in maximum BYI 02960 residue levels in tomato pollen of 107 µg/kg. The corresponding maximum residue level in tomato pollen of the metabolite BYI 02960-DFEAF was determined to be 4 µg/kg. The highest BYI 02960-residues were found during the first week after flower emergence and the residues declined thereafter.

1: active substance flupyradifurone

Description

The long-term effects of exposure of honeybees (*Apis mellifera* L.) to oil-seed rape, grown from seeds treated with BYI 02960 FS 480 G, and sprayed three times with BYI 02960 SL 200 G (1x bare soil before sowing and 2 x foliage spray) was tested under field conditions.

Location

Field experiment was conducted on a test field which was located in the north of Germany near the village Celle. No flowering crops were present in the surrounding area (2 km radius) of the test item field. Winter OSR was present at a distance of 1.7 and 0.9 km from the control fields.

Sizes field and crop, test condition (tunnel or field)

The overall size of the test field was 4.18 ha for the test item treatment plot and 5.08 ha for the control plot. Fields were separated by 7.0 km. The crop was oil-seed rape (OSR). Previous crops were potato

and grassland in the test item field, and maize and winter wheat in the control field. Several herbicides, fungicides and insecticides (no neonicotinoid insecticides) were used in both control and test item field in the previous crops.

Test substance

BYI 02960 FS 480G (480 g flupyradifurone/L nominal, 474.7 g/L actual, density 1.191 g/mL)
BYI 02960 SL 200 G (200 g flupyradifurone /L nominal, 198.6 g/L actual, 16.9% w/w, density 1.175 g/mL)

Treatments

Two treatment groups:

1) A seed treatment product BYI 02960 FS 480G and additional treatments with product BYI 02960 SL 200 G: one treatment on the bare soil (target rate 300 g as/ha, immediately incorporated into the upper 20 cm of the soil just before sowing) and two foliar applications (at a target rate of 205 g as/ha during immediate pre-/early flowering and full flowering) and
2) a control.

Application scheme is given in the table below.

Table 9.4.3-1 Treatments and number of colonies per field (1st spray September 7, 2010, 2nd spray at April 26, 2011 and 3rd spray at May 2, 2011)

Treatment Group	Sowing of winter OSR-seeds	Time of spray application	Application rate [g a.s./ha]	Application rate [L product/ ha]	Spray Volume	No. of colonies per field plot
Control (C)	OSR seeds, variety "Titan", only fungicide treated, September 2010, 6 kg seeds/ha (target)	-	-	-	-	6 + 2
BYI 02960 (T)	OSR seeds, variety "Titan", fungicide and BYI 02960 FS 480 G treated (10 g BYI 02960 a.s./kg OSR seeds, nominal), September 2010, 6 kg seeds/ha (target)	1st spray application at the day of sowing, before seed sowing, September 2010, (BBCH 00)	300 1)	1.500 1) BYI 02960 SL 200 G	200 L/ha	6 + 2
		2nd spray application at BBCH 59-60*, spring 2011	205 2)	1.032 2) BYI 02960 SL 200 G	200 L/ha	
		3rd spray application at BBCH 64-65*, spring 2011	205 2)	1.032 2) BYI 02960 SL 200 G	200 L/ha	

* Majority of plants
1) Referring to nominal content of a.s. (200 g/L)
2) Referring analysed content of a.s. (198.6 g/L)

Test concentrations

OSR seeds, dressed with the seed treatment BYI 02960 FS 480G, were drilled in on September 7, 2010, at a target rate of 6 kg OSR seeds/ha. Analysed seed treatment rate of 9.9 g flupyradifurone/kg seeds and a 1000 grain-weight of 8.6 g. The treated field plot was matched with a control field plot drilled at the same time with untreated OSR seeds. Three applications with BYI 02960 SL 200 G as specified in Table 1 (the first on the bare soil (September 7, 2010), second and third on the foliage (April 26 and May 2).

Species tested

Honey bees of the race *Apis mellifera*.

Population size

For the test, healthy colonies were used in hives with one brood box and one honey box including 11 combs each. The colonies contained approx. 6,000 to 12,000 bees. Just before set-up, control

colonies contained on average 8562 bees (6190-11028, n=6) and treatment colonies contained 9387 bees (8273-10184, n=6).

At the end of the exposure phase the colonies were split to reduce the size of the colonies (May 30, 2011 at DAS40). This is a common and necessary manipulation in order to restrict the urge of swarming. Only the original hives were used for assessments.

Timing placement hives under test conditions

At each field (control and treatment) eight bee colonies were placed in the plots before the second spray application of BYI 02960 SL 200 G at BBCH 59-60. They remained at the exposure location until the end of flowering (= exposure phase). Afterwards, the test colonies were relocated to a remote site, without extensive agricultural crops attractive to bees (= monitoring phase).

Parameters observed and timing thereof

The following parameters were observed during the exposure phase:

- Adult bee mortality
  - Number of dead bees in dead bee trap, 5 times in the pre-exposure period.
  - Number of dead bees in dead bee trap, linen sheets in front of the hives and linen sheets during exposure
- Flight intensity (mean number of bees/1 m^2/10-15 sec) measured in five marked areas, three times a day.
- Behaviour of the bees in the crop and around the hive was measured at least once a day for 1 minute, during flight intensity assessments.
- Condition of the colonies and development of the bee brood (number of bees (strength), mean abundances of the different brood stages per colony and assessment date, measured 0-2 days before moving the bees to the exposure site, no assessments during exposure phase, then assessments every three weeks at the monitoring site (first assessments within 2 days after set-up)
- Bee diseases and viruses, including *Varroa destructor* and *Nosema* sp., were checked at start and end of exposure phase and at start and end of overwintering phase.
- Residues. Soil samples were taken once directly after application to bare soil but before sowing. During exposure period continuous collection of OSR flowers and forager bees. Two of the eight hives per field were assigned for monitoring residues. Pollen, nectar and bee wax were collected once at the end of the exposure phase. Pollen and nectar were collected during the monitoring phase. Method for residue analysis:
  - Soil: analytical method 01074/M001 for BYI 02960 and its metabolite metabolites 6-chloronicotinic acid and difluoroacetic acid.
  - Bee wax: Modification M002 of the analytical method 01206 for the determination of residues of BYI 02960 and BYI 02960-Difluoroethylaminofuranone (=BYI 02960-DFEAF) by HPLC with electrospray and MS/MS-detection

- Pollen, nectar and flowers: Modification M001 of the analytical method 01206 for the determination of residues of BYI 02960 and BYI 02960-DFEAF by HPLC with electrospray and MS/MS-detection.

- Pollen source identification: Twice during the exposure phase at the test fields, pollen was collected from pollen traps. First collection of pollen between onset of flowering and full flowering. Second collection between full flowering and re-location to monitoring site.

Virus analysis

Bees were analysed for the bee viruses deformed wing virus (DWV), sacbrood virus (SBV), acute bee paralysis virus (ABPV), chronic bee paralysis virus (CBPV), Kashmir bee virus (KBV), Israel acute paralysis virus (IAPV) and black queen cell virus (BQCV) at start of exposure phase, end of exposure phase, and start and end of overwintering. Ten bees per hive were analysed.

Bee diseases

The presence of different pathogens (*Nosema* sp., *Malphigamoeba mellificae*, *Varroa destructor*, *Paenibacillus* larvae) in bee samples was determined at different time points during the observation period.

Statistical evaluation

Not performed.

Mortality quotients were calculated as the quotient of mortality in a particular period relative to mortality in the pre-treatment period. For the calculation mean mortality/colony/day is used. If Qm <1 then mortality after treatment is lower than before treatment.

Results

Actually applied concentrations

Amounts of seeds actually drilled deviated from anticipated by -0.4 and 0% in the test item and control. Actually applied spray applications were concentrations were 310.38 g as/ha in the first spray (deviation of 4.19%) and 204.05 g as/ha in the second spray (deviation 0.24%). The third spray contained 205.03 g as/ha (deviation 0.72%).

Climatic conditions

Temperatures, humidity and precipitation were recorded at the nearest official weather station at Celle, 15 and 13 km away from the exposure sites. No abnormal weather data were obtained.

Residue analysis

Method validation:

Mean recovery of BYI 02960 in flowers, pollen, nectar, beewax and soil were 91, 88, 97, 77 and 107% with corresponding relative standard deviations of 11.3, 7.2, 5.0, 10.0 and 1.9%.

Mean recovery of BYI 02960-DFEAF in flowers, pollen, nectar, and beewax were 89, 88, 93, 85% with corresponding relative standard deviations of 3.5, 5.5, 4.0 and 8.9%. For both parent and metabolite LOQ was 1 µg/kg and LOD was 0.1 µg/kg for flower, pollen and nectar. LOQ was 1 µg/kg and LOD was 0.3 µg/kg in beewax. For soil LOQ was 5 µg/kg and LOD was 1.5 µg/kg.

.

In the control, no residues were found in the flowers. No residues of parent nor metabolite was detected in pollen from combs, pollen from forager bees, nectar from combs, nectar from forager bees, beewax. All residues were <LOD. Residues in soil were not analysed in the control field. In the table below residues in the treated field are given.

Table 9.4.3-2 Residues of BYI02960 and BYI02960-difluoroethylaminofuranone (BYI02960-DFEAF) in samples of flowers, pollen, nectar, bee wax and soil, as obtained from the test item treatment group

Sample	Test Item	Subsample	Residue [µg/kg]	
			BYI 02960	BYI 02960-DFEAF
Flower	BYI 02960 FS 480 G + BYI 02960 SL 200 G	A	1917 - 30379	9 - 80
Pollen (combs)		A	305 - 3905	3 - 12
Pollen (bee bread)		A	4 - 1958	< LOD - 7
Pollen (forager bees)		A	246 - 14259	2 - 26
Nectar (combs)		A	428 - 1347	5 - 13
Nectar/ Honey		A	45 - 1409	< LOD - 30
Nectar (forager bees)		A	269 - 4108	< LOQ - 38
Beewax (combs)		A	6 - 148	< LOD - 2
Beewax		A	5 - 17	< LOD
Soil		A	75	-

BYI 02960-DFEAF = BYI 02960-difluoroethylaminofuranone (BCS-CC98193)
LOQ = Limit of Quantitation = 1 µg/kg in flower, nectar, pollen and beewax, respectively (BYI 02960 and BYI 02960-DFEAF); 5 µg/kg in soil (BYI 02960)
LOD = Limit of Detetction = 0.1 µg/kg in flower, nectar, pollen as well as 0.3 µg/kg in beewax, respectively (BYI 02960 and BYI 02960-DFEAF); 1.5 µg/kg in soil (BYI 02960)

Pollen source identification

In the control field **the percentage of OSR pollen was <1-31% on 10 days after set-up (DAS10) and 5-28% on DAS16 in colonies C1-C6. In colonies C7-C8 (for residues) percentages were 19 and 30% and 31 and 70% respectively.** ***Cotoneaster*** **was almost always the preferred pollen source.** ***Pyrus*** **spp. was sometimes more preferred, sometimes less preferred.** ***Acer*** **was the least preferred.**

In the test item treated field **the percentage of OSR pollen was 18-50% on DAS10 and 32-38% on DAS16 in colonies C1-C6. In colonies C7-C8 (for residues) percentages were 25-52% and 69-70% respectively.** ***Cotoneaster*** **was almost always the preferred pollen source.** ***Acer*** **and** ***Pyrus*** **spp. the least preferred. In the figure below the data on pollen sources are given.**

Figure 9.4.3-1 Pollen source identification in treatment (T) and control group (C) at DAS 10 (upper figure) and DAS 16 (lower figure). Colonies 7 and 8 were assigned to the residue analyses. Figure prepared by evaluator using data from tables 49-52.

Bee viruses

SBV, ABPV, CBPV, KBV and IAPV were not detected in any of the samples. DWV, BQCV and SBV were detected in some of the control hives, while the test item colonies did not contain any of the analysed bee viruses except BQCV in two colonies. Author concluded that no test item-related adverse effects on colony health in terms of virus infestation were observed.

Bee diseases

The results of the disease analysis revealed that the test item treated colonies were as healthy as the control colonies and as such, no bee disease-related adverse effects on colony health were observed.

Biological observations

Mortality

Results on mortality are reported in the following figures (copied from the report).

Results were based on dead bee traps in period -5 to -1DAS, and based on both dead bee traps and linen sheets in the period DAS0-24. Applications were performed at DAS6 and DAS12.

Figure 9.4.3-2 Mean number of dead bees per colony observed at the monitoring site before set-up at the field site (DAS-5 to DAS-1) and after set-up at the field sites before the 2nd spray application (DAS1 to DAS6).

Figure 9.4.3-3 Mean number of dead bees per colony observed at the field sites after the 2nd and before the 3rd spray application (DAS7 to DAS12).

Figure 9.4.3-4 Mean number of dead bees per colony observed at the field sites after the 3rd spray application until relocation of the colonies to the monitoring site (DAS13 to DAS24).

The mortality quotients during the entire exposure period were calculated to be 1.3 in C and 0.8 T, respectively. For the separate period these quotients were for the first period 1.5 in C and 0.5 in T, respectively, for the second period 1.5 in C and 0.8 in T, respectively and for the last period 1.2 in C and 0.9 in T, respectively. Only at DAS 13-15 (*i.e.* the three days directly following the second foliar

application) an elevation of mortality in the test item treatment was visible compared to the control. The author concluded that no test item-related adverse effects on mortality were observed.

Flight intensity

The mean flight activity was low in the period until DAS6 as flowers were in pre-flowering state. In the period from DAS6 to DAS12 just before 2nd foliarapplication, mean flight intensity amounted to 0.4 bees/m2/day in C compared to 0.9 bees/m2/day in T. After the 2nd foliar application (DAS12) mean flight intensity over the DAS12 to DAS 23 amounted to 1.0 bees/m2/day in C compared to 1.0 bees/m2/day in T. Total daily flight intensity was 0.6 bees/m2/day in C compared to 0.8 bees/m2/day in T. Flight intensity was very low in both C and T on the day of the 2nd foliar application. A clearly lower flight activity was observed at DAS13 and DAS14 after the 2nd foliar application. According to author, overall, no test item-related adverse effects on flight intensity were observed.

Figure 9.4.3-5 Mean number of forager bees per m2 assessed at the field sites after set-up of the colonies until shortly before the 3rd spray application (DAS0 to DAS12ba).

STD: standard deviation; ba: before application, aa: after application

Figure 9.4.3-6 Mean number of forager bees per m2 assessed at the field sites after the 3rd spray application (DAS12aa to DAS23).

STD: standard deviation; aa: after application

Behaviour

At the entrance of the treatment hives several test item-related adverse effects were observed such as clustering at the hive entrance (DAS6, DAS14), intensive cleaning behaviour (DAS10, DAS13 and DAS16), locomotion problems (DAS12, DAS13). No effect on behaviour was observed in the field. Anomalies were most visible on the day after 2nd foliar spray. The observations after the 2nd foliar spray application in T and the corresponding absence of this behaviour in the control indicate a possible correlation between the application of the test item during full flowering of the crop and during bee flight and the occurrence of intensive cleaning behaviour (10-30/hive) and locomotion problems (10-20/hive) in a small fraction of honeybees in the test item treatment group. According to author, these observed differences to the control were not adverse.

In the field, one single bee was noticed with behavioural problems at DAS12 (intensive cleaning behaviour) and one at DAS13 (suspended on plant), and two bees at DAS14 (intensive cleaning behaviour). No abnormal behaviour in the control was observed apart from one honeybee suspended on plant on DAS10.

Survey of flowering crops

In the surrounding area of the test item treatment field, no flowering crops were present within a 2 km radius during exposure of bees. Winter OSR was present at a distance of 0.9 and 1.7 km from the control field. According to pollen analysis wild trees and shrubs were present in the near surroundings of both treated as control field.

Abundance, brood development and food storage

Numbers of bees, brood development and food storage area are given the two figures below.

Assessments were made two days before set-up (April 19), after the end of the exposure period (May 16) and 8 observations in the monitoring period. Six hives situated in the control field and six hives in the treated field.

Numbers of bees per colony in control and treatment showed the same seasonal tendency in increases and decreases until the end of overwintering in March 2012. No test item-related differences in colony strength were noticed. It should be noticed that the decrease observed at June 6 is caused by splitting the colonies at May 30 into two colonies to reduce the natural urge of the colonies to swarm. Some brood and store combs were removed from the original colony and placed into a new hive (= nucleus). The empty spaces in both colonies (original and new) were filled with empty combs. The old queen was left in the original colony; the bees in the new colony were encouraged to rear a new healthy, egg-laying queen. The new colonies served as a back-up colony but were not further used for data sampling in this experiment.

Figure 9.4.3-7 Mean number of bees per colony in the control and test item treatment colonies.
STD: standard deviation

The author prepared figures for brood development and food storage area for each hive separately. The mean % comb coverage in the colonies in the control and the test item treatment group showed the same development, i.e. the same increase and decrease of brood cells (eggs, larvae and pupae) and food stores (nectar and pollen). No test item related adverse effects on brood development were observed.

Figure 9.4.3-8 Brood and food development of the colonies in the treatment and control group

Figure 9.4.3-9 Mean weight per colony of the control and test item treatment colonies.

The weight development of the colonies with its increases and decreases, measured from April 14 (DAS-6) to October 2011 (before overwintering) was very similar between the test item treatment and the control group.
Sudden weight changes to a larger extent in both exposure groups were observed at
14 May 2011: removal of hive material during relocation of the colonies to the monitoring site
30 May 2011, 27 July 2011: the removal of honey from the colonies
30 May 2011: bee colony splitting.
According to author, no test item related adverse effects on colony weight development were observed.

Conclusions of the author

The author concluded that exposure of honeybee colonies to flowering OSR, grown from seeds, seed-treated with flupyradifurone, one soil treatment and two foliage treatments with flupyradifurone (target rate of 300 g as/ha in the soil and a target rate of 205 g as/ha during immediate pre-/early flowering and full flowering), do neither cause acute, short-term nor long-term effects in exposed colonies, including colony health, colony vitality and overwintering performance. A possible correlation between the application of the test item during full flowering of the crop and during bee flight (3rd spray application) in terms of intensive cleaning behaviour and locomotion problems was observed in a small fraction of bees in the test item treatment group.

Remarks by evaluator

Splitting of the colonies occurred at May 30. This was done to reduce the urge of the colony to swarm. This urge to swarm is a normal phenomenon that occurs in healthy colonies by this period of the year. The author mentions that the colonies are reduced by removing some brood and store combs. It is not documented how many combs were removed. The methods bee keepers employ to split colonies depend on the region/country and may vary. In the Netherlands it is normal practice to take one comb with food (in which brood is not present). The box is further filled with artificial combs (template on which the bees can build new cells). The new colonies are further started with the introduction of a new queen and a certain number of bees (around 1000). A comb with brood is not introduced in order to prevent further Varroa infection. Sometimes a comb with open male brood is introduced. Any Varroa mites present on the bees will eagerly move into the male brood as the male larvae appear to be most attractive. Care must be taken to destroy the male brood before the male bees emerge.
The food combs that are removed from the hive contain not only nectar and pollen with residues of flupyradifurone (collected during exposure period until splitting of the colony), but also contain nectar and pollen collected before exposure. A logical question would be whether a particular comb would be taken out that could have a much lower or higher concentration of residues. From the study report it is not possible to reconstruct whether older or newly filled food combs were chosen. This also depends on the bee keepers methods. However, since only one or at the most a few combs are removed, the effect will be minimal, if present at all. Assumedly, the same type of food combs (fully or half filled) will have been chosen, so possible effects will be the same for all hives.

This necessary manipulation caused a drop in the bee numbers. Data of June 6 show a drop of bees that was more pronounce in the treatment than in the control. The growth of the colonies after this date was more or less similar (Figures 7 and 8). It can be concluded that the manipulation was necessary. Development of the colony is best evaluated starting from June 6.

No statistics were applied to data on mortality and flight intensity. However, as SD values of test item treatments and control were overlapping, significant differences are very unlikely. Concerning flight activity, less activity in the test item treatment is observed at DAS13-14, immediately after the 3rd application at DAS12. Thereafter higher flight intensity was observed in the test item treatments. This might be caused be a repellent effect of the product. This effect coincides with a higher mortality at DAS 13-15 and some behavioural problems at DAS13, 14 and 16. At other days mortality in the test item treatment was always lower than in the control in the period DAS0-24.

Figure 8 on mean weights of the colonies show that during the exposure period (2-14 May) the control colonies show an increase in weight that is stronger than in the parallel treated colonies. This difference might be caused by the treatments with flupyradifurone. However, this is difficult to evaluate as the control and treated fields were separated from each other. Therefore, foraging bees may have collected different quantities of nectar and pollen sources, depending on the availability of flowering plants. The pollen analyses showed that bees not only forage on the OSR crop but also forage on other crops/wild plants, preferably Cotoneaster. As bees in the treated colonies also foraged on other crops the exposure to flupyradifurone was less than 100%.

Colonies in the control field had two sources of OSR within 2 km distance. There is a high chance that these crops have been treated with neonicotinoids or other insecticides. Pesticide use in these crops has not been verified by the authors. Also, pollen source analysis revealed that a substantial part of the pollen had been derived from other plants such as Cotoneaster, Acer and Pyrus. Cotoneaster and Acer are probably plants/trees occurring in the wild that have not been treated with pesticides. Pyrus, however, may have been treated with several insecticides. This crop was however, less preferred. Thus, it is uncertain whether the control colonies were not contaminated by other insecticides/fungicides/herbicides. The residue analyses however showed that residues of flupyradifurone and its metabolite were not found in the flowers, pollen, nectar and beewax in the control. Given the agricultural landscape in Germany, there is not a better set-up of a field study possible. Higher exposure to flupyradifurone in the treated field is difficult to realize and exposure to pesticides in general in the control cannot be avoided.

In conclusion, no clear effects on mortality, flight intensity, brood and food storage area, and colony development were detected. Some possible short-term effects on mortality, flight intensity, behaviour and colony weight might have occurred after the 3rd application. There was however, a clear recovery from these effects. No effects on the capacity of the colony to overwinter are expected.

Expert discussion in Pesticide Peer Review meeting 124 (December 2014):
(Please note that the word 'effect' in the text below might be interpreted as different from the control (i.e. may or may not include effects from the treatment), pending on the context.)

The treatment regime was treated seed, soil spray and two foliar applications to the same crop. This study may be useful for the assessment for the risk to bees from residues in succeeding crops.

The evaluation of the RMS was agreed. Some potential effects were noted including some sublethal effects. Overall there was a suggestion that the observed effects do indicate some test item related effect. The RMS reflected that the treatment hives showed a slower increase in weight compared with the control colonies. The RMS stated that the reason for this was unknown i.e. it could be due to difference in hive location. The RMS noted that this data was difficult to interpret and it was questionable as to whether this was due to natural variation or was treatment related.

The study included an assessment of overwintering success. The final assessment was made in March the following year. There appeared to be no effects on the over wintering success.

A concern was raised during the commenting of the low flight intensity observed. The RMS noted they have discussed foraging intensity with experts and they consider that the criteria in the EPPO (2 - 3 bees per m^2 for OSR) is very difficult to achieve.

It was noted that the study included a statement to indicate that there were no major flowering crops within 2 km of the field. The new EFSA Guidance recommends that a survey is performed and to minimise alternative foraging opportunities (i.e. also for weeds, trees, bushes). The RMS considered that the conditions of this study were reasonable and realistic. It was acknowledged that the requirements of the EFSA GD are difficult to adhere to but is there to maximise 'worst-case conditions'. The question was raised as to whether multiple studies address the concern of replicating 'worst-case conditions'. Multiple studies increases the probability that 'worst-case conditions' are achieved but it would still need to be demonstrated that this has been achieved.

Overall, the experts in the meeting agreed with the RMS's conclusions on this study.

Study KIIIA 10.4.5/02

Characteristics

Abbreviation used:

DAS = days after set-up of hives (mind: not after sowing!)

1: active substance flupyradifurone

Description

The long-term effects of exposure of honeybees (*Apis mellifera* L.) to oil-seed rape, grown from seeds treated with BYI 02960 FS 480 G, and sprayed three times with BYI 02960 SL 200 G (1x bare soil before sowing and 2 x foliage spray) was tested under field conditions.

Location

Field experiment was conducted on a test field which was located in Alsace, France.

Sizes field and crop, test condition (tunnel or field)

The size of the field plots was approximately 4.54 ha (treated field plot) and approximately 4.11 ha (control field plot), respectively. The distance between the plots was approximately 8.0 km. The crop was oil-seed rape (OSR). Previous crops were maize and winter wheat in the test item field, and mustard and winter wheat in the control field. Several herbicides, fungicides, insecticides (no neonicotinoid insecticides) and a molluscicide were used in both control and test item field in the previous crops.

Active substance

BYI 02960 FS 480G (480 g flupyradifurone/L nominal, 474.7 g/L actual, density 1.191 g/mL)
BYI 02960 SL 200 G (200 g flupyradifurone /L nominal, 198.6 g/L actual, 16.9% w/w, density 1.175 g/mL)

Treatments

Two treatment groups:

1) A seed treatment product BYI 02960 FS 480G and additional treatments with product BYI 02960 SL 200 G: one treatment on the bare soil (target rate 300 g as/ha, immediately incorporated into the upper 20 cm of the soil just before sowing, based on nominal content of 200 g as/L) and two foliar applications (at a target rate of 205 g as/ha during immediate pre-/early flowering and full flowering, based on analysed content of 198.6 g as/L) and

2) a control.

Application scheme is given in the table below.

Table 9.4.3-2 Treatments and number of colonies per field (1st spray September 14, 2010, 2nd spray at April 9, 2011 and 3rd spray at April 18, 2011)

Treatment Group	Sowing of winter OSR-seeds	Time of spray application	Application rate [g a.s./ ha]	Application rate [L product/ ha]	Spray Volume	No. of colonies per field plot

		3rd spray application at BBCH 64-65, spring 2011	205 2)	1.032 2) BYI 02960 SL 200 G	200 L/ha	

* Majority of plants
1) Referring to nominal content of a.s. (200 g/L)
2) Referring analysed content of a.s. (198.6 g/L)

Test concentrations

OSR seeds, dressed with the seed treatment BYI 02960 FS 480G, were drilled in on September 14, 2010, at a rate of 6.89 kg OSR seeds/ha (target rate: 6 kg seeds/ha). Analysed seed treatment rate of 10.1 g flupyradifurone/kg seeds and a 1000 grain-weight of 9.0 g. The treated field plot was matched with a control field plot drilled at the same time with untreated OSR seeds. Three applications with BYI 02960 SL 200 G as specified in Table 1 (the first on the bare soil, on September 14, 2010, second and third on the foliage on April 9 and April 18, 2011).

Species tested

Honey bees of the race *Apis mellifera*.

Population size

For the test, healthy colonies were used with young bees (1 queen and approx. 10,000 to 20,000 bees per colony) in hives with one brood body and one honey body including 10 combs each. Just before set-up (DAS-1), control colonies contained on average 12063 bees (6000-16625, n=6) and treatment colonies 12917 bees (7875-17875, n=6).

At the end of the exposure phase the colonies were split to reduce the size of the colonies (June 01, 2011 at DAS54). This is a common and necessary manipulation in order to restrict the urge of swarming.

Timing placement hives under test conditions

At each field (control and treatment) eight bee colonies were placed in the plots one day before the second spray application of BYI 02960 SL 200 G at BBCH 55-61. They remained at the exposure location until the end of flowering (= exposure phase). Afterwards, the test colonies were relocated to a shared monitoring site (at least BBCH 69), without extensive agricultural crops attractive to bees.

Parameters observed and timing thereof

In order to determine the pre-exposure level of mortality, the number of dead bees in the dead bee traps was counted over a period of 4 days before the start of exposure (i.e. first day of contact of the honeybees with the crop) at the monitoring site.

The following parameters were observed during the exposure phase:

- Adult bee mortality
  - Number of dead bees in dead bee trap, over a period of 4 days in the pre-exposure period.
  - Number of dead bees in dead bee trap, linen sheets in front of the hives and linen sheets during exposure
- Flight intensity (mean number of bees/1 m^2/10-15 sec) measured in five marked areas, three times a day.
- Behavioural observations of the bees were carried out in the flight assessment areas once a day during 30 sec after one of the flight intensity assessments when bees were observed.
- Behavioural observations of the bees returning to the entrance of the hives was observed (over approximately 1 minute) once a day during flight activity in front of the hives and on the same days as the mortality and flight intensity assessments (in both, treatment and control).

- On DAS-1, just before relocation of the colonies from the monitoring site to the exposure site, the assessment of colony health, strength and brood development was conducted for each of the colonies (including the hives that were used as residue monitoring colonies). On DAS33, the bee colonies were transported to the monitoring site where the colony health and strength as well as the brood development was assessed on DAS35.
  Thereafter and for the entire duration of the study, a time interval of approximately 3 weeks was followed for further colony assessments. Until the end of the swarming season (beginning of July), five additional, less invasive colony beekeeper checks were performed between the three-weekly colony assessments on DAS21, DAS41 (only T1-T6 and C1-C6), DAS61, DAS69 and DAS90. No assessments were carried out during overwintering (between 06 October 2011 and 21 March 2012) and during the exposure phase (except for measures to prevent swarming of the colonies). At each colony assessment, the comb area containing bees and cells with nectar, pollen, eggs, larvae and capped cells were estimated per comb side and the total number of bees and cells containing the brood stages, pollen and nectar per hive were calculated.
- The colony health and strength as well as the brood development were assessed as follows (= invasive colony assessments):
  - Strength of the colony (estimation adapted to IMDORF & GERIG, 1999, and IMDORF et al., 1987)
  - Presence of a healthy queen; verified by the presence of freshly laid (one day old) eggs
  - Estimate of the pollen storage area and area with nectar stores (Estimation adapted to Imdorf & Gerig, 1999, and Imdorf et al., 1987)
  - Estimate of the area containing egg, larval and capped cells (Estimation adapted to IMDORF & GERIG, 1999, and IMDORF et al., 1987)
  - Weight of the colony
  - Colonies were assessed for bee diseases according to standard beekeeping practice
- Residues. Soil samples were taken once directly after the application to bare soil just before sowing. During exposure period continuous collection of OSR flowers and forager bees. Two of the eight colonies per field were assigned for monitoring residues. Pollen, nectar and bee wax were collected once at the end of the exposure phase. Pollen and nectar from the residue monitoring colonies were collected during the exposure phase and after relocation to the monitoring site.
  Method for residue analysis:
  - Soil: analytical method 01074/M001 for BYI 02960 and its metabolite metabolites 6-chloronicotinic acid and difluoroacetic acid, by HPLC-MS/MS
  - Bee wax: Modification M002 of the analytical method 01206 for the determination of residues of BYI 02960 and BYI 02960-Difluoroethylaminofuranone (=BYI 02960-DFEAF) by HPLC with electrospray and MS/MS-detection

- Pollen, nectar and flowers: Modification M001 of the analytical method 01206 for the determination of residues of BYI 02960 and BYI 02960-DFEAF by HPLC with electrospray and MS/MS-detection.

- Pollen source identification: Twice during the exposure phase at the test fields, pollen was collected from pollen traps (DAS3, DAS12). First collection of pollen between onset of flowering and full flowering. Second collection between full flowering and re-location to monitoring site.

Virus analysis

Bees were analysed for the bee viruses deformed wing virus (DWV), sacbrood virus (SBV), acute bee paralysis virus (ABPV), chronic bee paralysis virus (CBPV), Kashmir bee virus (KBV), Israel acute paralysis virus (IAPV) and black queen cell virus (BQCV) at start of exposure phase, end of exposure phase, and start and end of overwintering. At least ten bees per hive were analysed.

Bee diseases

The presence of different pathogens (*Nosema* sp., *Malphigamoeba mellificae*, *Varroa destructor*, *Paenibacillus* larvae) in bee samples was determined at different time points during the observation period.

Statistical evaluation

Not performed.

Mortality quotients (QM) were calculated as the quotient of mortality in a particular period relative to mortality in the pre-treatment period. For the calculation mean mortality/colony/day is used. If Qm <1 then mortality after treatment is lower than before treatment

Results

Actual applied concentrations

Amounts of seeds actually drilled deviated from anticipated by 14.8 and 7.5% in the test item treatment and control. Actually applied spray applications were 310.5 g as/ha in the first spray (deviation of 3.5%) and 208 g as/ha in the second spray (deviation 1.5%). The third spray contained 212 mg as/ha (deviation 3.3%).

Climatic conditions

Temperatures, humidity and precipitation were recorded at the nearest weather station in Sélestat (approximately 17 km away from the test item treatment field). No abnormal weather data were obtained.

Residue analysis

Method validation:

Mean recoveries of BYI 02960 in flowers, pollen, nectar, beewax and soil were 97, 97, 99, 83 and 107%, respectively, with corresponding relative standard deviations of 5.5, 5.9, 8.6,14.1 and 1.9%.

Mean recoveries of BYI 02960-DFEAF in flowers, pollen, nectar, and beewax were 91, 95, 100 and 82%, respectively, with corresponding relative standard deviations of 3.3, 5.5, 6.1 and 9.9%.

For both parent and metabolite LOQ was 1 µg/kg and LOD was 0.1 µg/kg for flower, pollen and nectar. LOD for beewax was 0.3 µg/kg. For soil LOQ was 5 µg/kg and LOD 1.5 µg/kg.
In the control, BYI02960 or BYI02960-DFEAF were found above the LOQ in one single sample out of 121 analysed samples in total; 6 µg/kg in pollen from combs, hive residue monitoring . No residues of parent nor metabolite > LOQ were detected in pollen from forager bees, nectar from combs, nectar from forager bees, beewax. Residues in soil were not analysed in the control field. In the table below residues in the treated field are reported.

Table 9.4.3-3 Residues of BYI02960 and BYI02960-difluoroethylaminofuranone (BYI02960-DFEAF) in samples of flowers, pollen, nectar, bee wax and soil, as obtained from the test item treatment group

Sample	Test Item	Subsample	Residue [µg/kg]	
			BYI 02960	BYI 02960-DFEAF
Flower	BYI 02960 FS 480 G + BYI 02960 SL 200 G	A	84 – 36000	< LOQ – 47
Pollen (combs)		A	4 – 1200	< LOD – 6
Nectar (combs)		A	12 – 920	< LOD – 5
Beewax (combs)		A	< LOQ – 39	< LOD
Pollen (forager bees)		A	170 – 21000	LOQ – 21
Nectar (forager bees)		A and B	< LOD – 4300	< LOD – 26
Soil		A	61	-

BYI 02960-DFEAF = BYI 02960-difluoroethylaminofuranone (BCS-CC98193)
LOQ = Limit of Quantitation = 1 µg/kg in flower, nectar, pollen and beewax, respectively (BYI 02960 and BYI 02960-DFEAF); 5 µg/kg in soil (BYI 02960)
LOD = Limit of Detetction = 0.1 µg/kg in flower, nectar, pollen as well as 0.3 µg/kg in beewax, respectively (BYI 02960 and BYI 02960-DFEAF); 1.5 µg/kg in soil (BYI 02960)

Pollen source identification

In the control field, the percentage of OSR pollen collected per hive was 23-48 % on DAS3 and 16-33 % on DAS12 in the colonies C1 to C6. In the two residue monitoring colonies of the control, the percentage of OSR pollen collected per hive was 36-39 % on DAS3 and 13-16 % on DAS12. In the test item treatment field, the percentage of OSR pollen collected per hive was 28-43 % on DAS3 and 38-69 % on DAS12 in the colonies T1 to T6. In the two residue monitoring colonies of the test item treatment group, the percentage of OSR pollen collected per hive was 32-52 % on DAS3 and 42-50 % on DAS12. In the figure below the data on pollen sources are given.

Figure 9.4.3-10 Pollen source identification in treatment (T) and control group (C) at DAS 3 (upper figure) and DAS 12 (lower figure). Figure prepared by evaluator using data from tables 49-52.

Bee viruses

ABPV, CBPV, KBV and IAPV were not detected in any of the samples. DWV was detected in some control and treatment hives. BQCV and SBV were detected in some of the control and treatment hives.

Before start of exposure, no differences in bee virus infestation were observed between the control and the test item treatment colonies. After end of exposure, SBV and BQCV was detected in three of the test item treatment colonies, whereas no viruses were found in any of the control colonies. However, before start of overwintering, no differences in bee virus infestation between the control and the test item treatment colonies were observed anymore. At the end of overwintering, none of the colonies of both exposure groups did contain any of the analysed bee viruses. Author concluded that no test item-related adverse effects on colony health in terms of virus infestation were observed.

Bee diseases

The results of the disease analysis revealed that the test item treated colonies were as healthy as the control colonies and as such, no bee disease-related adverse effects on colony health were observed.

Biological observations

Mortality

Results on mortality are reported in the following figures (copied from the report).

Figure 9.4.3-11 Mean number of dead bees per colony observed at the monitoring site before set-up at the field site (DAS-3 to DAS0) and at the field sites before the 2nd spray application (DAS1).

Figure 9.4.3-12 Mean number of dead bees per colony observed at the field sites after the 2nd and before the 3rd spray application (DAS2 to DAS10).

Figure 9.4.3-13 Mean number of dead bees per colony observed at the field sites after the 3rd spray application until end of flowering (DAS11 to DAS31).

The mortality quotients during the entire exposure period (DAS1-DAS31) were calculated to be 1.1 for both T and C. For the separate period these quotients were 1.3 in C and 2.0 in T for the first period (DAS1), 1.5 in C and 1.4 in T for the second period (DAS2 – DAS10), and 0.9 in both C and T for the last period (DAS11-DAS31). From DAS11 to DAS23 the mean number of dead bees per colony per day in the control was higher than the mortality in the treatment. From DAS24 to DAS31 the mean

number of dead bees per colony per day in the treatment was higher than in the control (with the exception of DAS26) (remark evaluator).

The author concluded that no test item-related adverse effects on mortality were observed.

Flight intensity

The mean flight activity in the period until DAS1ba was low, as flowers were in pre-flowering state. In the period from DAS1 after 2nd application to DAS10 just before 3rd application, mean flight intensity amounted to 0.8 bees/m2/day in C compared to 1.1 bees/m2/day in T. Immediately before the 3rd spray application of the test item (DAS10ba), the mean flight intensity was 1.6 bees/m2/day in the control compared to 6.6 bees/m2/day in T. After the 3rd spray application (DAS10) mean flight intensity over the DAS10aa to DAS 31 amounted to 1.5 bees/m2/day in C compared to 1.8 bees/m2/day in T. Total daily flight intensity during exposure from DAS0 to DAS31 was 1.3 bees/m2/day in C compared to 1.6 bees/m2/day in T. A clearly lower flight activity was observed at DAS14 (2 days after the 3rd application; remark evaluator). According to author, overall, no test item-related adverse effects on flight intensity were observed.

Figure 9.4.3-14 Mean number of forager bees per m2 assessed at the field sites after set-up of the colonies until shortly before the 3rd spray application (DAS0 to DAS10ba).

STD: standard deviation; ba: before application, aa: after application

Figure 9.4.3-15 Mean number of forager bees per m2 assessed at the field sites after the 3rd spray application (DAS10aa to DAS23).
STD: standard deviation; aa: after application

Behaviour

In general, only single or a low number of bees with abnormal behaviour (locomotion problems, cramping en trembling) was observed. No data were reported on behaviour at the entrance of the hives for DAS3 and DAS4. In both treatment and control there were several days at which a larger number of bees (up to 246) were motionless. On DAS9 in both the control and the treatment group 5 bees were cramping. Cramping took place in both control and treatment (max. 7 bees).
Trembling was reported taking place both in the control (max. 3 bees) and in the treatment (max. 10 bees on DAS14 in the treatment). On DAS13, 10 bees showed intensive cleaning behaviour in the control.
Locomotion problems were found in the control (max.10) and treatment group (max. 5 bees).
In those cases where larger numbers were observed (246 motionless bees on DAS22 and approximately 85 motionless bees on DAS25 in C), this could be attributed to rainfall events in the area. At the entrance of the hives several test item-related adverse effects were observed such as locomotion problems, cramping and trembling but with only a few bees per day. In both C and T there were days that a number of bees was motionless. On DAS12, clustering at the entrance was found in the control group.
In the test field no unusual foraging behaviour was observed.

Abundance, brood development and food storage

Numbers of bees, brood development and food storage area are given the two figures below.

Assessments were made just before relocation of the colonies to the exposure site (DAS-1) for all eight colonies, including those assigned for residue analysis, and after the end of the exposure period (DAS35) for the remaining six colonies, 10 observations in total.

Almost all colonies of the study showed all brood stages at all assessment dates during the observation period except in late summer and autumn, when the natural period of breeding activity of the colonies ended. Where exceptions were noticed (e.g. short-term loss of an egg-laying queen), control and test item treatment group, were equally affected.

After overwintering, all colonies of the control and the test item treatment group were found to be alive and having resumed breeding activity, except colony T2. The missing brood activity in T2 in early spring was most likely caused by experimental activities resulting in the death of the queen of T2 immediately before start of overwintering and is therefore not considered to be a test item-related effect.

Numbers of bees per colony showed the same seasonal tendency in increases and decreases until the end of overwintering in March 2012. No test item-related differences in colony strength were noticed.

Figure 9.4.3-16 Mean number of bees per colony in the control and test item treatment colonies.
STD: standard deviation

Figure 9.4.3-17 Brood and food development of the colonies in the treatment and control group

Figure 9.4.3-18 Mean weight per colony of the control and test item treatment colonies.

The weight development of the colonies with its increases and decreases, measured from April 5 (DAS-3) to October the 5th 2011 (before overwintering) was very similar for the test item treatment and the control group.

Sudden weight changes to a larger extent in both exposure groups were observed at
23 May 2011 and 4 August 2011: removal of honey bodies
June 1, colony splitting.
14 September 2011: feeding of the colonies
According to author, no test item related adverse effects on colony weight development were observed.

Survey of flowering crops

In the surrounding area of the test item field a few flowering cherry trees were present during exposure of the bees. In the surrounding area of the control field no flowering crops were present during exposure of the bees.
According to pollen analysis wild trees and shrubs were present in the near surroundings of both treated as control field.

Conclusions of the author

The author stated that treatment as performed in this study, did neither cause acute, short-term nor long-term adverse effects in the exposed colonies.

Remarks by evaluator

Splitting of the colonies occurred at June 1. This was done to reduce the urge of the colony to swarm. This urge to swarm is a normal phenomenon that occurs in healthy colonies by this period of the year. The author mentions that the colonies are reduced by removing some brood and store combs. It is not documented how many combs were removed. The methods bee keepers employ to split colonies depend on the region/country and may vary. In the Netherlands it is normal practice to take one comb with food (in which brood is not present). The box is further filled with artificial combs (template on which the bees can build new cells). The new colonies are further started with the introduction of a new queen and a certain number of bees (around 1000). A comb with brood is not introduced in order to prevent further Varroa infection. Sometimes a comb with open male brood is introduced. Any Varroa mites present on the bees will eagerly move into the male brood as the male larvae appear to be most attractive. Care must be taken to destroy the male brood before the male bees emerge.
The food combs that are removed from the hive contain not only nectar and pollen with residues of flupyradifurone (collected during exposure period until splitting of the colony), but also contain nectar and pollen collected before exposure. A logical question would be whether a particular comb would be taken out that could have a much lower or higher concentration of residues. It is not possible to reconstruct whether older or newly filled food combs were chosen. This also depends on the bee keepers methods. However, since only one or at the most a few combs are removed, the effect will be minimal, if present at all. Assumedly, the same type of food combs (fully or half filled) will have been chosen, so possible effects will be the same for all hives.
This necessary manipulation caused a drop in the bee numbers. It was not documented how many brood and store combs and worker bees/forager bees were removed. Data of June 21 show a clear drop of bees. The growth of bee numbers after this date was more or less similar in control and treatment (Figure 7). It can be concluded, the manipulation of the colonies was necessary.

Development of the colony is best evaluated starting from June 21. The reduction of mean number of brood and food cell between at June 1 as compared with May 13 (Figure 17) cannot be explained by reviewer as colony separation only took place after colony assessment.

No statistics were applied to data on mortality and flight intensity. Although the SD values of test item treatments and control were overlapping in most cases, and significant differences are very unlikely, the mean number of dead bees from DAS 24 to DAS 31 was higher in the treatment than in the control for every single day in that period (with the exception of DAS26), Furthermore, the mean number of forager bees per m2 assessed at the field sites after the 3rd spray application was higher in the treatment than in the control on every single day from DAS20 to DAS23. No data were available from DAS24 to DAS31.
Regarding the flight activity: on DAS1aa and DAS10ba the mean number of forager bees per m2 assessed at the field sites in the treatment was higher than the control values, SD values were not overlapping.

Data on behaviour of the honeybees at the entrance of the hives on the second (DAS3) and third day (DAS4) after the 2nd application are not reported. Therefore it is not possible to assess the behaviour in the days following the 2nd application. However, the potential impact on behaviour is expected to have been greatest after the 3rd application (foliar application during full flowering and active foraging), and then, no treatment-related effects on behaviour were seen.

Although no flowering crops were found within 2 km of the field sites, the pollen analyses showed that bees not only foraged on the OSR crop but also on other crops/wild plants, preferably Pyrus and Brassica. Pesticide use in these crops has not been verified by the authors. Both Pyrus and Brassica, may have been treated with several insecticides. Thus, it is still uncertain whether the control colonies were not contaminated by other insecticides/fungicides/herbicides. The residue analyses however showed that no residues of flupyradifurone and its metabolite were found in the flowers, pollen, nectar and beewax of the control with the exception of one sample (13 September 2011) of pollen that contained 6 µg/kg residue BYI 02960.

In conclusion, no clear effects on mortality, flight intensity, brood and food storage area, colony development, behaviour and colony weight were detected. Some possible effects on mortality and flight intensity might have occurred after the 3rd application. If so, these did not result in effects on colony development before and after overwintering.

Expert discussion in Pesticide Peer Review meeting 124 (December 2014):
(Please note that the word ‘effect’ in the text below might be interpreted as different from the control (i.e. may or may not include effects from the treatment), pending on the context.)

The treatment regime was treated seed, soil spray and two foliar applications to the same crop (performed in France).

Some potential effects were observed on forager mortality and bee brood. The hive weight in the treated groups was consistently higher than the control. How worst case the conditions were, was also questioned with respect to the dilution of alternative food etc. There was 60% dilution in the treated group pollen being brought back to the hive. The nectar data (residues) also indicted dilution from non-contaminated food. It was noted that one pollen sample in the control contained residues of the test item indicating contamination. This was surprising because the treatment and control hives were 8 km apart. The RMS noted that this was only 1 sample out of 121 samples and therefore the RMS did not consider this to be an issue. It was suggested that it may have been due to a mistake in the residue analysis in the laboratory.

Flight intensity was also noted to be low in relation to the criteria given in the EPPO 170 Test Guideline. The RMS reflected on this in the reporting table in the same way as for the field study above.

The experts noted that, in general, the studies were well designed. The conclusion of the RMS on this field study was agreed.

Description

The short- and long-term effects of exposure of honeybees (Apis mellifera L.) to BYI 02960-fortified carbohydrate and protein diet was tested under semi-field conditions in gauze tunnels, followed by relocation of the hives to the monitoring location where the honey bees were allowed to forage freely for the remainder of the study.

Location

The confined exposure part of the study was conducted close to Burscheid, North Rhine-Westphalia, Germany and the post-exposure period took place at Monheim, Germany, approx. 20 km away from the exposure location.

Sizes field and crop, test condition (tunnel or field)

Exposure location

The experiment comprised five blocks, each consisting of four differently treated plots - one untreated control and three test-item treatments, resulting in 20 plots in total. Each plot consisted of a pre-installed gauze tunnel, which harboured one randomly assigned honey bee colony at the beginning of the confinement period, resulting in 5 replicates per exposure group (i.e. C, T1, T2, T3). The gauze tunnels were erected on perennial ryegrass, cut short regularly inside the tunnels, which prevented the presence of flowering weeds. Size of the tunnels: approximately 20 m long, 5 m wide and 3 m high (center). Total field size in the confined exposure period: 9920 m2.

Monitoring location

Colonies were set-up corresponding to their positions during the confined exposure period at a distance of 5 m between colonies to minimize drifting of bees from one colony to another.

Active substance

BYI 02960 tech., purity 96.2% w/w, batch-code: BYI 02960-01-03.

Treatments

One untreated control and three test-item treatments: 600 (T1), 2500 (T2) and 10000 (T3) µg BYI 02960 as/kg diet. Throughout the acclimation and exposure period, the honey bee colonies received ad libitum "sugar diet" (i.e. sugar + syrup, for carbohydrate supply) and "pollen diet" (i.e. pollen +

syrup, for protein supply, see below) and had further ad libitum access to tap water, provided via a drinking trough.

The pollen diet was provided inside the respective hives, whereas the sugar diet was offered in Petri-dishes outside the hive, placed about 1 m above the ground, in two feeders per hive (the exact location of the feeders in the tunnels was not reported, but based on a picture in the report it seems that one feeder was placed relatively close to the hive and another more on the other side of the tunnel).

Sugar diet and pollen diet were replenished three times a week (Monday, Wednesday and Friday) and the remainder of the respective diet was reweighed to determine the actual food consumption of the colonies.

During periods where honey bees did not sufficiently forage on the sugar diet and/or during periods of elevated carbohydrate demand (e.g. spells of cold or rainy weather, etc.) – treatment specific supplemental syrup was placed inside the colonies (in case supplemental syrup was provided, all colonies received the identical quantity). The increments of supplemental syrup were always completely taken up by the colonies within a short period of time.

Preparation of the diet

The test item was first dissolved in an Ethanol/Milli-Q-Water (50/50, v/v) and further diluted with unfortified Ethanol/Milli-Q-Water (50/50, v/v), so that three differently concentrated spiking solutions were prepared, which were used to spike all the different diets (i.e. sugar-, syrup- and pollen diet) at the three different BYI 02960-treatment levels.

Control and test item spiked sugar diet consisted of 66.67% w/w solid Apipuder® + 33.33% w/w liquid Apiinvert®). The pollen diet was prepared as dough, made up with finely-ground, natural, bee-collected, fresh pollen of multi-floral origin, mixed with concentrated, commercial sugar syrup (Apiinvert®). The appropriate amount of the spiking solutions or control solutions was added to the liquid Apiinvert®, the mixture was stirred for several minutes and increments of solid Apipuder® were added under continuous stirring until the final mixing ratio was obtained for each individual batch. Once a homogenous sugar dough had been formed, the stirring continued for a further several minutes to assure a homogenous distribution of BYI 02960 within the sugar dough.

The sugar diet was prepared as a dough, made up with finely-ground, commercial sucrose powder (Apipuder®), mixed with concentrated, commercial sugar syrup (Apiinvert®), and control and test item spiked supplemental syrup was added.

Side experiment

A comparison of the overall mean actual concentration of BYI 02960 in the sugar diet before and after the actual exposure to confined honey bee colonies during the biological course of the study revealed approx. 25% lower concentrations after honey bee feeding when compared to the concentrations before feeding. In contrast, virtually no difference in diet concentrations was observed in the corresponding pollen diet before and after feeding.

Species tested

Honey bees of the race Apis mellifera.

Population size

For the test, healthy, queen-right colonies were used. All test colonies were prepared at the same time and equalised for adult worker bees, brood and food stores as reasonably possible. At the beginning of the test, each colony contained one laying sister queen and consistently four occupied frames with nominally 2500 honey bees, in a hive with one brood chamber; three of the four occupied frames were brood frames, one frame contained bee-bread (pollen) and honey. For the confinement period of the study, three empty frames were added to each hive to allow an expansion of the colony. The quantity of the bee-bread (pollen)- and honey stores was adjusted to allow a thriving of the colonies for about one week, just enough, to maintain colony vitality throughout the acclimation period under confined conditions.

Timing placement hives under test conditions

The colonies were first trained (training period) to find and accept the feeders (located in the tunnel outside of the hive, which harboured the sugar diet (i.e. sugar + syrup)), and were then allowed to further acclimate to the confined conditions, during which all colonies received untreated (control) diet (acclimation period). At the end of the acclimation period, gauze-tunnels/bee colonies were randomly assigned to one of the four exposure groups (i.e. C, T1, T2, T3), respectively. The total confined pre-exposure period lasted for about 1 1/2 weeks, with one week on control diet at the routine feeding regime. One colony per individual tunnel, set-up close to one end of the tunnel.

The acclimation period was followed by a 6 week exposure period (end of April 2011 until mid of June 2011). After the exposure period, the test colonies were relocated to a monitoring site where the colonies were maintained according to apicultural practice until overwintering.

Parameters observed and timing thereof

The following parameters were observed during the exposure phase:

- Honey bee mortality (i.e. dead worker bees, drones, larvae and pupae) was measured on a daily basis for a period of 49 days in succession, i.e. for 7 days during the confined acclimation period and for 42 days during the confined exposure period:
    - Number of dead bees in dead bee trap
    - Number of dead worker bees, drones, larvae and pupae on a piece of cloth with a surface of appr. 50 x 50 cm directly in front of the hives
    - dead worker bees and drones (as well as larvae and pupae, if any) were collected and counted on water-permeable polyethylene-mesh-sheets (width approximately 30 - 50 cm), which were installed along the walls of every gauze tunnel
    - mortality on the perennial ryegrass, if any was also recorded, but no formal counts were made
- Foraging activity (flight activity) during confinement was assessed daily; the number of bees foraging on the sugar diets was recorded during two 3-minute observation periods per feeder and tunnel/colony, respectively
- The colony health and strength as well as the brood development were assessed during the acclimation and exposure period at weekly intervals:

  - Estimation of number of adult honey bees covering the comb cell area per comb side (estimation adapted to IMDORF & GERIG, 1999, and IMDORF et al., 1987)
  - Estimation of the area containing egg, larval and capped cells by means of an estimation frame
  - Presence of a healthy queen; verified by the presence of freshly laid (one day old) eggs
  - Estimate of the pollen storage area and area with nectar stores
  - Colonies were assessed for bee diseases according to standard beekeeping practice
  - Varroa infestation was monitored just before set-up inside the tunnels, at the end of the acclimation period, in the middle of the exposure period and at the very end of the exposure period/just at the beginning of the post-exposure observation period
- Food consumption was measured every Monday, Wednesday and Friday during the acclimation and exposure period; the amount of consumed sugar- and pollen diet was determined by re-weighing the respective diets
- Behavioural anomalies were recorded whenever observed:
  - Exaggerated motility, aggressiveness
  - Discoordinated movements (trembling, flight incapability, etc.),
  - Apathy, lethargic behaviour,
  - Clustering at the bee hive entrance,
  - Clustering on the gauze netting of the tunnel,
  - Obvious symptoms of intoxication (cramping, agony, etc.)

Bee diseases and virus analysis

Honey bee and nectar/honey samples were taken at the start of acclimation phase, start of exposure phase, before and after overwintering and were analysed:

In total,

- 76 honey bee samples for disease/pathogen analysis (Nosema sp., Malpighamoeba mellificae and Varroa destructor),

- 76 nectar/honey samples for the analysis of AFB (American foul brood; i.e. presence of Paenibacillus larvae spores)

- 76 honey bee samples for the analysis of EFB (European foul brood; i.e. presence of Melissococcus plutonius),

- and 76 honey bee samples for virus analysis (DWV [deformed wing virus], SBV [sacbrood virus], ABPV [acute bee paralysis virus], CBPV [chronic bee paralysis virus], KBV [Kashmir bee virus], IAPV [Israel acute paralysis virus] and BQCV [black queen cell virus]) for the bee viruses deformed wing virus (DWV), sacbrood virus (SBV), acute bee paralysis virus (ABPV), chronic bee paralysis virus (CBPV), Kashmir bee virus (KBV), Israel acute paralysis virus (IAPV) and black queen cell virus (BQCV).

The presence of different pathogens (Nosema sp., Malphigamoeba mellificae, Varroa destructor, Paenibacillus larvae spores, Melissococcus plutonius) in bee samples was determined at different time points during the observation period.

Chemical analysis

Actual BYI 02960-concentration in samples of spiked sugar- and pollen diet were determined by reversed phase High Performance Liquid Chromatography (HPLC), coupled with electrospray and tandem mass spectrometry (MS/MS) detection, according to method 01206/M001.

Climatic conditions

Climatic conditions (such as daily min./max. temperature, air humidity, rainfall, sunshine hours, average wind speed, etc.) were obtained from the weather station on the premises of Bayer CropScience AG's experimental station Höfchen (< 1 km distance to the gauze tunnels) throughout the confined exposure period of the study. From the beginning of the post-observation field monitoring period (including the overwintering period) to the end of the study climatic data data were obtained from the weather station on the premises of Bayer CropScience AG's Headquarters in Monheim am Rhein (approx. 5 km distance to the Laacher Hof post-exposure field monitoring location).
Throughout the confined exposure period of the study, the actual temperature inside the gauze tunnels was recorded by means of calibrated data loggers, placed evenly spaced in the different tunnels across the study site.

Statistical evaluation

Single factor ANOVA was employed for testing for significant differences of the endpoints described above between any of the exposure groups. Normal distribution of data was tested with the Shapiro-Wilk test; homogeneity of residuals was tested by applying the Brown-Forsythe test (i.e. the Levene test, by using the median instead of the mean) to the fitted model. In case homogeneity of residuals was rejected, the non-parametric Kruskal-Wallis test was performed. In case of a rejected H0, the control response was compared with the response of the different test item treatment levels via a Kruskal test, corrected for multiple comparisons (Siegel and Castellan, 1988).

Results

During the exposure period, two out of the 20 colonies differed in food uptake and/or mortality from the other colonies, and infections/infestation could not be excluded. One colony in control (colony 6) which showed little foraging activity, little food consumption and which had practically collapsed at the end of the confinement period and one colony in test item treatment group T1 (colony 8) which showed an increased mortality at the end of the confined exposure period with bees showing disease-like symptoms. In order to prevent any spread of potential bee diseases on the monitoring location, these two colonies (colony 6-tunnel 17, colony 8-tunnel 13, T1) were excluded. All statistical analyses of data were conducted without control colony 6 in order to avoid any potential bias due to this non-performing control colony. The bee data from colony 8 in tunnel 13 (T1) were not excluded from the statistical analyses when relating to the confinement period. This procedure was selected to apply a conservative approach to the data evaluation and because colony 8 - unlike colony 6, performed most of the time (during confinement) as the other T1 -colonies and was still vital.

Chemical analysis

In the fresh pollen (used for the preparation of the control and treated pollen diet), no residues above the Limit of Detection (LOD, 0.3 ug/kg) were found for all neonicotinoid insecticides under investigation (i.e. acetamiprid, thiacloprid, clothianidin, thiamethoxam and imidacloprid) in any of the pollen samples.

Actual applied BYI 02960-concentration in the diet

Residues of BYI 02960 in the control sugar- and pollen diet and the batches of the control sugar syrup were always below LOD, i.e.<0.1 ug/kg.

The mean actual BYI 02960-concentration in the pollen diet sampled before exposure to the honey bees colonies ranged from 80 to 94%, with RSD values below 6.1%; the corresponding mean actual concentration sampled after exposure ranged from 80 to 92%, with RSD values below 8.5%.

The mean actual BYI 02960-concentration in the sugar diet sampled ranged from 76 to 91% of nominal before exposure of the bees, with RSD values below 7.8%; the corresponding mean actual BYI 02960-concentration in the sugar diet sampled after exposure ranged from 47 to 68% of nominal, with RSD values below 13.4%. Moreover, during sampling and handling of the sugar diet, it was regularly noticed that samples of the sugar diet after being exposed to honey bees were less doughy and more crystalline in comparison to the samples before exposure to honey bees. This phenomenon was not observed for the pollen diet. To assess whether the lower actual concentrations of BYI 02960 in the sugar diet after foraging by honey bees was the result of selective foraging on the two components of the sugar diet (i.e. crystalline sucrose powder and sugar syrup), a side experiment was performed. In this experiment, an aliquot of a representative BYI 02960-spiked sugar diet was centrifuged and samples from the more liquid (upper layers) and the more solid part (lower layers) were analysed. The analytical data revealed actual BYI 02960 concentrations in the upper layer of the centrifuged BYI 02960-spiked sugar diet in a range from 208 to 233% of nominal, whereas the actual BYI 02960 concentrations in the middle and lower layer of the centrifuged BYI 02960-spiked sugar diet ranged from 58 to 63% of nominal. It was further investigated whether bees forage selectively on the more liquid part of the sugar diet, which in turn would result in lower actual concentrations of BYI 02960 in the sugar diet remainders after bee exposure. For this, BYI 02960-spiked sugar diet was placed in feeders inside gauze tunnels placed side by side in the field, either with or without honey bees actively foraging on the spiked sugar diet and the remainders were analysed.

Actual concentrations of BYI 02960 in the sugar diet before the exposure in the side experiment were within the range of 82 to 92% of nominal (total average: 88%; n=24). The actual BYI 02960-concentration in the sugar diet after foraging ranged from 23 to 63% of nominal (total average: 45%; n=12), whereas in the concurrently exposed spiked sugar diet without foraging, concentrations ranged from 72 to 94% of nominal (total average: 85%; n=12). The side experiment thus indicates that the lower actual concentration in the spiked sugar diet after exposure does not originate from dissipation or decomposition of BYI 02960, but originates from the selective uptake of the more liquid phase of the sugar diet by honey bees. This is further supported by the fact that BYI 02960 was found to be mainly located in the more liquid phase of the sugar diet and that the sugar diet was generally found to

be more crystalline after bee exposure. Furthermore, no decline of concentrations was found in the pollen diet after honey bee exposure.

Consumption of sugar- and pollen diet during confinement

The total average consumption of sugar- and pollen diet during the confined exposure period was not statistically significant different in any of the three test item treatment groups (i.e. T1, T2 and T3) as compared to the control,except for one single occasion (feeding interval) in exposure group T2 with a higher consumption. Consumption of the sugar diet was lowest in all groups during the confined acclimation phase. According to the author, this observation can be explained by the fact that the colonies during this period needed to adapt their feeding regime to the new situation inside the tunnels and still relied during this period on their in-hive resources, which they concurrently used-up.

Table 9.4.3-4 (copied from the original report). Consumption of sugar diet was measured on every feeding-/diet exchange event from 2011-05-04 onwards. The values are the mean sugar diet consumption from both feeders averaged over all tunnels per exposure group (NB: Colony 6-tunnel 17 (control) is not included in the presented data).

The consumption of pollen diet showed a regular pattern with a peak every third feeding interval. This peak is caused by the employed feeding regime which included an extra consumption day between Friday and Monday. For those instances where H0 had to be rejected, post-hoc testing did not reveal any statistically significant difference between the control and any of the test item treatments. There was no significant difference between the total average pollen diet consumption during the confined exposure period in each of the three test item treatment groups (i.e. T1, T2 and T3) when compared to the control.

Table 9.4.3-6 (copied from the original report). Consumption of pollen diet as measured on every feeding-/diet exchange event from 2011-05-04 onwards. The values are the mean pollen diet consumption averaged over all tunnels

per exposure group

According to the author an aggravated foraging situation (cold night temperatures and exposure to rather strong and cold easterly winds during daytime) in combination with the still on-going adaptation to obtain carbohydrates from the feeder, is in line with the low consumption of the sugar diet during the acclimation period.

Nectar/Honey stores

The average number of cells containing nectar or honey is presented in the following figure.

Figure 9.4.3-19 Nectar/Honey stores, determined as the average number of cells containing nectar or honey per exposure group as evaluated during each colony assessment throughout the course of the study.

At the end of the exposure period (2011-06-20) the average number of nectar/honey cells was to some extent lower in T1 than in the other groups, but not statistically significantly different. This was at least partially caused by colony 8 (2800 nectar/honey cells), which was no longer continued after the confinement period.

According to the author, the lower number of cells at the first colony assessment at the monitoring location can be explained by the re-adaptation of colonies from their feeding habits during the confined conditions.

Figure 9.4.3-20 Consumed honey (kg) during overwintering as calculated by subtracting the honey stores before overwintering (2011-10-24) from those after overwintering (2012-03-21), under the assumption that one cell contains 0.3125 g honey. Values are given as the average amount per exposure group.

Pollen stores

The average number of cells containing pollen or bee bread is reported in the following figure.

Figure 9.4.3-21 Pollen/Bee bread stores, determined as the average number of cells containing pollen or bee bread per exposure group as evaluated during each colony assessment throughout the course of the study.

The data of 2nd colony assessment revealed that the originally available pollen stores were depleted or almost depleted in all bee hives at the end of the acclimation period. Throughout the entire exposure period, none of the cells within the control or treated colonies contained any pollen/bee bread.

At the first colony assessment on the monitoring location after relocation (9th colony assessment), the average number of cells containing pollen/bee bread indicates that colonies had re-adapted to their routine flower/pollen foraging and pollen storage. The higher average number of cells containing pollen/bee bread at this date in the control was caused by colony 1 (11960 cells with pollen/bee bread), which became the home of a swarm of bees (so the number of bees in the colony was greatly increased). The higher colony strength caused higher pollen collection and the bees from the swarm did not have to re-adapt to routine flower/pollen foraging as did the other colonies of the study. To prevent biased conclusion during the further course of the study, the swarm was conservatively extracted from colony 1 on 01 AUG 2011, on the basis of the available brood data of the current and the preceding colony assessment under consideration of the number of adult bees at the development of the other C-colonies during this period. An elevated number of cells with pollen/bee bread in colony 1 was still observed at the next colony assessment, after correction for the swarm, thereafter, the number of cells with pollen/bee bread in colony 1 had returned to the range of other C-colonies. Statistical analyses did not detect any significant differences in pollen/bee bread stores between the different exposure groups during the entire confinement period, during the entire post-exposure monitoring period as well as after overwintering, respectively (ANOVA analysis: Ho accepted on each of the 15 colony assessment dates).

Honey bee disease and virus analysis

The occurrence of pathogens and viruses occurred across all exposure groups, but was not linked to the absence or presence of the test item in the respective exposure group. Results are reported in the following figure.

Figure 9.4.3-22 Disease- and virus occurrence, determined as the average number of occurrences* per exposure group and evaluated at four distinct dates during the course of the study. (* disease occurrence was coded in a binary system for each disease and hive - i.e. if a particular disease was present in a colony, the colony received a "1", if this particular disease was not present it received a "0". From this coding, average values were calculated per treatment group)

Overall, no test-item related adverse effects on colony health in terms of pathogen/bee disease and virus infestation were observed during the entire course of the study. Throughout the 17 consecutive measurements, there was only one date (19 OCT 2011) where the ANOVA analysis of the data regarding the Varroa infestation resulted in a rejection of Ho and were subsequent post-hoc testing revealed a significant difference between the control treatment and treatment T2. However, the author states that, as the difference occurred on a very low absolute level (0.5 mites in C, 3 mites in T2), only at one single measurement out of 17, about 1 month after a successful anti-Varroa treatment with formic acid, the observed isolated statistical difference is neither considered test-item treatment related nor of any apidological or apicultural relevance.

Table 9.4.3-8 Differences in the average number of number of Varroa-mites, dropped and counted on Varroaboards underneath each hive, between control and any test item treatment (ANOVA, Ho rejected). An asterisk (*) indicates the test item treatment that differs significantly from the control (NB: Colony 6-tunnel 17 (control) is not included in the presented data; colony 8-tunnel 13 of T1 was not continued after the end of confinement)

Date	Control		T1		T2		T3		Statistical Test
	mean	± SD	mean	± SD	mean	± SD	mean	± SD	
2011-10-19	0.45	0.38	1.00	0.43	2.96*	1.50	1.12	0.83	ANOVA, p=0.007; Dunnett, p=0.004

Honey bee mortality in front of the hive and at the tunnel walls during confinement

No significant differences were observed for the total sum of dead individuals, except for worker bee mortality at the tunnel edges, which was significantly lower in exposure T1 as compared to control. Mortality in front of the hives did not differ significantly between the control group and exposure groups T1 and T3, respectively, throughout the entire confinement period; post-hoc testing revealed a significantly higher worker bee mortality in treatment group T2 than in the control on 2 out of 49 days of confinement. However, the author reports that these two occasions are isolated in time and the

difference in relation to control performance on these two days is well within the range of natural variability and is apidologically not relevant.

Bee mortality at the tunnel walls in T1 was significantly lower than in the three days during the confinement period, for T2 this was the case on two days For T3, no significant differences were observed regarding the daily mean values of dead worker bees at the tunnel walls. Since there was no consistent pattern in the mortality figures and because mortality was lower in the respective test item treatment groups than in control, the authors conclude that differences can be attributed to the natural variability. This is supported by the fact that the differences between trial days were larger than the differences between treatments.

Drone mortality as well as mortality of immature life stages (larvae and pupae) was low in all exposure groups throughout the entire confinement period.

Table 9.4.3-9 (copied from original report). Total number of dead honey bees in front of the hive as well as on the sheets at the tunnel walls, separated in dead worker bees, drones and immature stages (i.e. larvae and pupae). All values recorded during the confined acclimation and exposure period (i.e. 2011-05-02 - 2011-06-20, 49 days) were summed for each tunnel per exposure group.

Behaviour

Except for colony 8 in tunnel 13 of T1, which exhibited disease like symptoms towards the end of the confined exposure period, sometimes associated with increased motility, no abnormal behaviour was recorded in the tunnel tents or around and in the hives during the confinement period or throughout the post-exposure monitoring period.

Foraging activity (flight activity) during confinement

Presented numbers are the number of bees observed on the two feeders during a total of 12 minutes counting time (2x 3 min per feeder, 2 feeders/hive). Additionally, the total number of honey bees on the gauze tunnel roof and walls was estimated in order to detect any indication of possible repellent/anti-feedant phenomena (no such indication was found; results not shown). Flight intensity increased from a total average of 5 honey bees visiting the feeder at the second day of confinement (i.e. during the acclimation period), to a total average of 97 feeder visiting honey bees at the first day of exposure, indicating a continuously increasing acceptance of the feeders during the acclimation period. At the start of the exposure period, the total average of honey bees visiting the feeder was within the range observed during the remaining confinement period (23 - 246). Foraging activity on each single day throughout the confinement period was similar in all exposure groups.

The statistical analysis of the daily foraging activity data revealed significant differences between one of the three exposure groups and the control on 5 occasions (days) throughout the 49 days confinement period; On three out of these 5 occasions, exposure group T3 exhibited a significantly lower foraging activity than the control, on the other two occasions, foraging activity in exposure group T1 was significantly lower as compared to control.

No significant difference was observed for the total average number of foraging honey bees in the test item treatments when compared to control performance. The total average consumption of sugar diet during was not statistically significantly different between the test item treatment groups and the control. ,There was also no statistical significant difference between the consumption of the sugar diet within two subsequent feeding events (“feeding interval”) in the exposure groups when compared to control.

Overall, the development of the colonies was homogenous throughout the confinement period of 7 weeks. No statistically significant difference in the average colony strength was observed at any of the colony assessments conducted throughout the course of the study, when comparing the performance of each test item treatment group with control performance.

The somewhat higher colony strength in C at the end of the experiment was caused by colony 1 (12498 bees). The author states: this elevated number of adult honey bees could potentially have been recruited/bred by the colony itself, but could also be the result of bees that entered the colony from outside (i.e. acceptance of
another swarm during winter/early springtime). However, the latter seems more realistic. The position of colony 1 at the edge of the bee stand increased the probability of catching swarms, colony 1 already accepted a swarm before and appeared to be particularly inclined to accept swarms and the amount of brood cells in colony 1 did not vary accordingly from the other colonies.

Colony brood status/brood development

Table 9.4.3-13 Average number of brood cells (i.e. eggs + worker bee larvae + worker bee pupae) per exposure group

Colony assessment	C	T1	T2	T3

3. end of exposure period	**9160**	**10112**	**11968**	**9240**
4. beginning of August	**19800**	**24400**	**27000**	**25416**
5. end of August	**27240**	**24280**	**28520**	**20328**
6. end of October	**1830**	**2670**	**1056**	**1920**
7. middle of March 2012	**6270**	**3770**	**6560**	**5328**

Throughout the post-exposure observation period, there were no distinct differences when comparing the average colony brood status amongst C, T1, T2 and T3, respectively. The statistical analysis revealed a significant difference in 1 out of 15 colony assessments, where in the average number of total brood cells in T2 was significantly higher than in the control.

Colony strength after confinement period

Once the colonies were allowed to forage freely, intra-group variability increased, irrespective of the exposure group. Throughout the entire post-exposure observation period, however, there were no distinct differences when comparing the average colony strength amongst C, T1, T2 and T3, respectively. The average number of honey bees per exposure group at the last colony assessment accounted to 6079, 4053, 4752 and 4174 in C, T1, T2 and T3, respectively.

Conclusions of the author

The author concludes that the continuous exposure of honey bee colonies under confined conditions to BYI 02960 concentrations of up to and including 10000 µg as/kg diet has not resulted in adverse acute, short-term and long-term effects on mortality, colony strength and -development, brood development, food storage, honey bee behaviour, queen survival, overall hive vitality and colony health, as well as on overwintering performance.

Remarks by evaluator

The test item was unequally distributed in the sugar diet. However, based on the side-experiment which looked at the feed intake and the distribution of the a.s. in the feeders, it can be concluded that the intake achieved in the study was at least as high as the nominal concentrations.

Field history of the monitoring site (previous crops and use of pesticides) is not reported. The first colony assessment after set-up of the colonies under field conditions took place three weeks after relocation. The author states that one control colony (no. 6 tunnel no. 17) out of the five colonies was not included in the results since the colony practically collapsed at the end of confinement. Furthermore, another control colony (colony 1, 31500 bees), became the home of a swarm of bees. The authors applied a correction in numbers based on the available brood data of the consecutive colony assessments and the number of adult bees of the other C-colonies during this period. The evaluator does not agree with the inclusion of the corrected data for this colony; the colony should not be included in the control data. The low number of replicates (especially in the control, with only three remaining replicates) and the apparent variation within the treatment groups in mortality of bees/drones/immature stages make it difficult to draw conclusions on the effect of the treatment. What can be concluded is that, under the specific circumstances of this study, the different treatments of the test substance do not lead to an adverse effect in one of the observed parameters (or the combination of adverse effects of the different parameters) to such an extent, that it led to the collapse of one or more colonies.

Expert discussion in Pesticide Peer Review meeting 124 (December 2014):
(Please note that the word 'effect' in the text below might be interpreted as different from the control (i.e. may or may not include effects from the treatment), pending on the context.)

It was noted that this study design was novel and may be useful to address the uncertainties of field studies (discussed above and in the EFSA GD). The experts noted that this study ensure adequate exposure to the test item but may be unrealistic and too high. The use of this type of study could be problematic in risk assessment as the conditions are too severe to be considered as a field-type study. The study could be considered as an extended lab-type study.

This study only covers oral exposure and not contact.

The RMS noted that only 3 of the 5 control colonies survived making it not possible to detect all types of effects. The RMS considered that the study was sufficient to assess overwintering success. This was questioned since all three treatment groups were less in weight than the control (up to 33%). The RMS noted that this was explained in the study report and DAR. The apparent difference could be explained that one of the control colonies was abnormally high which was hypothesised may have been due to swarming bees coming in to the hive. This cannot be confirmed with the available data. This is problematic to consider and may affect the interpretation of the results. The RMS noted that their assessment concluded only that the treatment hives survived. No conclusion regarding the health of the treated hives could be reached given the insufficient number of controls.

The experts agreed with the assessment of the RMS indicating that the study was useful for assessing overwintering success only.

Since the formulation used in this study (seed treatment formulation BYI02960 FS 480 g) is not proposed in the EU GAP, the executive summary and the full evaluation of the study were taken from the Canadian Pesticide Management Regulatory Agency (PMRA) review of flupyradifurone (Tier 2 summary of the ecotoxicologicval studies of the plant protection product Sivanto 200 SL dd. 26/04/2013). .

EXECUTIVE SUMMARY

This study was designed to determine residues of BYI 02960 in guttation liquid, collected from winter oil-seed rape (winter OSR), grown in BYI 02960-treated soil from seeds, seed-treated with BYI 02960 FS 480 G (nominal content of a.s., 480 g BYI 02960/L). The study was carried out under field conditions in Lower-Saxony, Germany, from autumn 2010 to spring 2011. The residue analysis was an integral part of this study.

Winter oil-seed rape (OSR) seeds, seed-treated with the insecticidal seed treatment product BYI 02960 FS 480 G at a rate of actually 9.9 g BYI 02960 a.i./kg OSR seeds (nominally: 10 g a.i./kg OSR seeds), were sown on a field plot in Northern Germany, in September 2010 at a rate of 5.98 kg seeds/ha (nominally: 6 kg seeds/ha; equivalent to 60 g a.i./ha) on 07 Sep 2010. The BYI 02960-treated winter OSR seeds were additionally dressed with a standard fungicide (Thiram = TMDT). The size of the field plot was 4.2 ha.

Before the actual sowing of the BYI 02960 FS 480 G-treated OSR-seeds, a spray application with the test item BYI 02960 SL 200 G was carried out at the same day on the bare soil, followed by immediate mechanical soil incorporation into the upper 20 cm of the soil. The application rate of this spray application was 1.5 L product/ha (actually: 310 g a.i./ha). The total application is estimated to be 370 g a.i./ha when considering both application methods as the total. The last sampling day was 230 days after the application of treated seed plus soil application.

In the BYI 02960-treated field plot, droplets of guttation liquid were collected from the surface of the treated winter OSR plants. The collection of guttation liquid started as soon as the plants had emerged (BBCH 9-10) and guttation occurred. Guttation liquid was sampled in autumn 2010 on 20 dates during a period of approximately 5 weeks after emergence, and in spring 2011 on 10 dates during a period of 6 weeks before the start of flowering. The collected guttation liquid samples were analysed for residues of BYI 02960 and its metabolite BYI 02960-difluoroethylaminofuranone.

Residues of BYI 02960 above the limit of quantitation (LOQ; 0.010 mg/L) were found in 20 out of 20 analysed samples during the sampling period in autumn 2010 and ranged between 11 mg/L on the third sampling date in 2010 (20 Sep 2010; highest value during the autumn sampling period) and 0.039 mg/L on the last sampling date (19 Oct 2010; lowest value during the autumn sampling period); at the first sampling date in autumn 2010 (18 Sep 2010), the BYI 02960 concentration in guttation liquid accounted to 9.0 mg/L. Generally, residues of BYI 02960 declined by about two orders of magnitude over the 5 week autumn sampling period (2010).

Residues of BYI 02960-difluoroethylaminofuranone (BYI 02960-DFEAF) above the limit of quantitation (LOQ; 0.010 mg/L) were found in 2 out of 20 analysed samples during the sampling period in autumn 2010. The two occasions with BYI 02960-DFEAF residues >LOQ were the first and the third day of sampling (18 and 20 Sep 2010) and BYI 02960-DFEAF residues ranged between 0.020 mg/L (20 Sep 2010; highest value during the autumn sampling period) and 0.013 mg/L (18 Sep 2010; lowest value during the autumn sampling period). In all other samples from 2010, residues of BYI 02960-DFEAF were < LOQ (i.e. < 0.010 mg/L).

Residues of BYI 02960 above the limit of quantitation (LOQ; 0.010 mg/L) were found in 10 out of 10 analysed samples during the sampling period in spring 2011, and ranged between 0.21 mg/L on 05 Apr 2011 (highest value during the spring sampling period) and 0.014 mg/L on 22 Mar 2011 (lowest value during the spring sampling period).

Residues of BYI 02960-difluoroethylaminofuranone (BYI 02960-DFEAF) during the sampling period in spring 2011 were always (i.e. in 10 of 10 analysed samples) below the limit of quantitation (i.e. < LOQ; < 0.010 mg/L).

B. Study design and methods

1. Experimental treatments

Location: The field site was located in the region Lower-Saxony, Germany.

Crop: Winter OSR seeds, seed-treated with the insecticidal seed treatment BYI 02960 FS 480 G, were sown on a field plot in Northern Germany, in autumn 2010. The size of the test field plot was 4.2 ha.

Before the actual sowing of the BYI 02960 FS 480 G-treated winter OSR-seeds, a spray application with the test item BYI 02960 SL 200 G was carried out at the same day on the bare soil of the field plot, followed by immediate mechanical soil incorporation into the upper 20 cm of the soil. The application rate of this spray application was 1.5 L product/ha (actually: 310 g a.s./ha).

The sowing rate was 5.98 kg seeds/ha.

After the end of winter OSR flowering in 2011, the whole winter OSR was destroyed.

Samples of guttation liquid were taken from the surface of several winter OSR plants and from at least 10 different locations across the test field. Droplets were collected with glass capillaries, and the guttation liquid was subsequently transferred to a micro test tube. On each sampling day, the sampling was conducted approximately at the same time of the day (in the morning).

Sampling of guttation liquid started on 18 Sep 2010 after the winter OSR plants had emerged and as soon as guttation was observed (BBCH 9-10). After the emergence of the plants and start of guttation, sampling was conducted daily on the first 7 days. After this period, three to four samplings were performed per week. In total, 20 samplings were conducted during autumn 2010.

In 2011, sampling of guttation liquid was continued. The samplings started approximately 6 weeks before flowering (full flowering was reached at the end of April). During this period, samplings followed a sporadic pattern, with 1 or 2 samplings per week. Sampling stopped when the winter OSR reached BBCH 59-60 (yellow bud stage, first flowers open). In total, 10 samplings were conducted during spring 2011.

No minimum amount of guttation liquid to be collected per sampling date was specified. The time which was spent to collect guttation droplets from the surface of the plants was less than two hours per sampling date. If more than 0.5 g guttation liquid could be sampled on one sampling date, the sample was split in two sub-samples (A and B) with at least 0.5 g remaining in sub-sample A.

Verification of sowing rates: Quantities of the sown seeds were verified by comparison of the weight of the seeds in the seed hoppers at the start and end of sowing to calculate the actually sown quantities of seeds.

Spray application technique: The application of the spray solution was carried out with spraying equipment typical for commercial applications. The test item (BYI 02960 SL 200 G) was weighed in the

laboratory. An appropriate amount of spray-tank solution was prepared immediately before each application and transported to the field site in the spraying device. After the spray application, the actually applied volume/amount of spray solution was determined by weighing the remaining spray solution.

The spray application was performed under the following conditions:

cropless soil (followed by immediate mechanical soil incorporation), just before sowing of BYI 02960-treated winter OSR seeds (BBCH 00) on the same day

air temperature less than 25 °C

average wind speed less than 3 m/s

Storage and Shipment: All collected samples were stored deep frozen (≤ -18°C) as soon as possible after sampling until residue analysis. All samples were shipped deep frozen from Niefern to the principal investigator for residue analysis Ralf Schoening, Bayer CropScience AG, Monheim, Germany. Storage and shipment conditions were recorded by use of a datalogger or min/max thermometer. The principal investigator at Bayer CropScience AG in Monheim was responsible for determining the levels of residues of BYI 02960 and BYI 02960-difluoroethylaminofuranone (BYI 02960-DFEAF) in guttation liquid samples collected from winter OSR plants.

2. Observation and measurements

Samples of guttation liquid were taken from the surface of several winter OSR plants and from at least 10 different locations across the test field. Droplets were collected with glass capillaries, and the guttation liquid was subsequently transferred to a micro test tube. On each sampling day, the sampling was conducted approximately at the same time of the day (in the morning).

The growth stage (BBCH code) of the winter OSR plants was recorded on each day of sampling.

For each day of the sampling periods in autumn 2010 and spring 2011, weather data (temperature, relative air humidity and rainfall) was collected by a nearby weather station (non-GLP records).

All collected samples were stored deep frozen (≤ -18°C) as soon as possible after sampling until residue analysis.

Residue analysis of guttation liquid from winter OSR plants was performed by using High Performance Liquid Chromatography (HPLC), coupled with electrospray and tandem mass spectrometry (MS/MS) detection according to method 01206/M001 (BCS report number MR-10/037, R. Schöning, P. Köster, 2011-03-28). The Limit of Quantitation (LOQ) of BYI 02960 and BYI 02960-DFEAF, defined as the lowest validated fortification level, was 1 µg/kg for all matrices tested in the method (bees, pollen, honey/nectar, green plant material and flowers/blossoms), respectively. The Limit of Detection (LOD)

of BYI 02960 and BYI 02960-DFEAF, for the matrices tested within the method, ranged from 0.1 to 0.2 µg/kg, respectively.

For the matrix guttation liquid, a full validation set was included in this study. The Limit of Quantitation (LOQ) of BYI 02960 and BYI 02960-DFEAF defined as the lowest validated fortification level was 10 µg/L for guttation liquid, respectively. The Limit of Detection (LOD) of BYI 02960 and BYI 02960-DFEAF was 1 µg/L for guttation liquid, respectively.

RESULTS AND DISCUSSION

Residues of BYI 02960 above the limit of quantitation (LOQ; 0.010 mg/L) were found in 20 out of 20 analysed samples during the sampling period in autumn 2010 and ranged between 11 mg/L on the third sampling date in 2010 (20 Sep 2010; highest value during the autumn sampling period) and 0.039 mg/L on the last sampling date (19 Oct 2010; lowest value during the autumn sampling period); at the first sampling date in autumn 2010 (18 Sep 2010), the BYI 02960 concentration in guttation liquid accounted to 9.0 mg/L. Generally, residues of BYI 02960 declined by about two orders of magnitude during the approximately 5 weeks lasting autumn sampling period.

Residues of BYI 02960-difluoroethylaminofuranone (BYI 02960-DFEAF) above the limit of quantitation (LOQ; 0.010 mg/L) were found in 2 out of 20 analysed samples during the sampling period in autumn 2010. The two occasions with BYI 02960-DFEAF residues >LOQ were the first and the third day of sampling (18 and 20 Sep 2010) and BYI 02960-DFEAF residues ranged between 0.020 mg/L (20 Sep 2010; highest value during the autumn sampling period) and 0.013 mg/L (18 Sep 2010; lowest value during the autumn sampling period). In all other samples from 2010, residues of BYI 02960-DFEAF were < LOQ (i.e. < 0.010 mg/L).

Residues of BYI 02960 above the limit of quantitation (LOQ; 0.010 mg/L) were found in 10 out of 10 analysed samples during the sampling period in spring 2011, and ranged between 0.21 mg/L on 05 Apr 2011 (highest value during the spring sampling period) and 0.014 mg/L on 22 Mar 2011 (lowest value during the spring sampling period).

Residues of BYI 02960-difluoroethylaminofuranone (BYI 02960-DFEAF) during the sampling period in spring 2011 were always (i.e. in 10 of 10 analysed samples) below the limit of quantitation (i.e. < LOQ; < 0.010 mg/L).

Table 10.4.5.3-1: Residues of BYI 02960 and BYI 02960-DFEAF in samples of guttation liquid

Sample	Origin	Date of sampling	Residue [mg/L]	
			BYI 02960 (min - max)	BYI 02960-DFEAF (min - max)
Guttation liquid	Winter-OSR seedlings/ plants, grown from BYI 02960960 dressed	18 September 2010 - 19 October 2010	0.039 - 11.0	< LOQ - 0.020

	seeds, sown in BYI 02960 treated soil	15 March 2011 -25 April 2011	0.014 - 0.21	< LOQ

Residues of BYI 02960and its metabolite BYI 02960-DFEAF are given as a range of the minimum and maximum values as obtained throughout different time periods (several weeks in autumn / spring, respectively) during which the samples had been collected
BYI 02960-DFEAF = BYI 02960-difluoroethylaminofuranone (BCS-CC98193),
LOQ = Limit of Quantitation = 10 µg/L in guttation liquid (BYI 02960 and BYI 02960-DFEAF)

Study Reliability and Discussion of Deficiencies

This study is considered fully reliable. No deficiency is noted.

CONCLUSION

A field study was conducted to determine residues of BYI 02960 in guttation liquid, collected from winter oil-seed rape (winter OSR), grown in BYI 02960-treated soil from seeds, seed-treated with BYI 02960 FS 480 G.

Residues of BYI 02960 above the limit of quantitation (LOQ; 0.010 mg/L) were found in 20 out of 20 analysed samples in autumn 2010 (quantifiable residues ranging from 11 mg/L to 0.039 mg/L). Generally, residues of BYI 02960 declined by about two orders of magnitude during the approximately 5 weeks lasting autumn sampling period.

Residues of BYI 02960 above the limit of quantitation (LOQ; 0.010 mg/L) were found in 10 out of 10 analysed samples in spring 2011; (quantifiable residues ranging from 0.21 mg/L to 0.014 mg/L).

Residues of the metabolite BYI 02960-DFEAF were < LOQ (i.e. < 0.010 mg/L) except for 2 out of 10 analysed samples (collected in the first and third day of sampling; quantifiable residues ranging from 0.020 mg/L to 0.013 mg/L) in autumn 2010 and for all samples (10 of 10) collected in spring 2011, respectively.

Since the formulation used in this study (seed treatment formulation BYI02960 FS 480 g) is not proposed in the EU GAP, the executive summary and the full evaluation of the study were taken from the Canadian Pesticide Management Regulatory Agency (PMRA) review of flupyradifurone (Tier 2 summary of the ecotoxicological studies of the plant protection product Sivanto 200 SL dd. 26/04/2013).

EXECUTIVE SUMMARY

This study was designed to determine residues of BYI 02960 in guttation liquid, collected from winter oil-seed rape (winter OSR), grown in BYI 02960-treated soil from seeds, seed-treated with BYI 02960 FS 480 G (nominal content of a.s., 480 g BYI 02960/L). The study was carried out under field conditions in Alsace, France, from autumn 2010 to spring 2011. The residue analysis was an integral part of this study.

Winter oil-seed rape (OSR) seeds, seed-treated with the insecticidal seed treatment product BYI 02960 FS 480 G at a rate of actually 10.11 g BYI 02960 a.s./kg OSR seeds (nominally: 10 g a.s./kg OSR seeds), were sown on a field plot in Alsace, France, in September 2010 at a rate of actually 6.89 kg seeds/ha (nominally 6 kg seeds/ha) on 14 Sep 2010. The BYI 02960-treated winter OSR seeds were additionally dressed with a standard fungicide (Thiram = TMDT). The size of the field plot was approximately 4.5 ha.

Before the actual sowing of the BYI 02960 FS 480 G-treated OSR-seeds, a spray application with the test item BYI 02960 SL 200 G was carried out at the same day on the bare soil, followed by immediate mechanical soil incorporation into the upper 15-20 cm of the soil. The application rate of this spray application was 1.5 L product/ha (actually: 311 g a.s./ha).

In the BYI 02960-treated field plot, droplets of guttation liquid were collected from the surface of the treated winter OSR plants. The collection of guttation liquid started as soon as the plants had emerged (BBCH 9-11) and guttation occurred. Guttation liquid was sampled in autumn 2010 on 20 dates during a period of approximately 5 weeks after emergence, and in spring 2011 on 8 dates during a period of approximately 3 weeks before the start of flowering. The collected guttation liquid samples were analysed for residues of BYI 02960 and its metabolite BYI 02960-difluoroethylaminofuranone (BYI 02960-DFEAF) using HPLC with electrospray and MS/MS-detection.

Residues of BYI 02960 above the limit of quantitation (LOQ; 0.010 mg/L) were found in 20 out of 20 analysed samples during the sampling period in autumn 2010 and ranged between 21 mg/L on the first sampling date in 2010 (26 Sep 2010; highest value during the autumn sampling period) and 0.087 mg/L on 20 Oct 2010 (lowest value during the autumn sampling period); at the last sampling date in autumn 2010 (29 Oct 2010), the BYI 02960 concentration in guttation liquid accounted to 0.26 mg/L. Generally, residues of BYI 02960 declined by about two orders of magnitude during the approximately 5 weeks lasting autumn sampling period.

Residues of BYI 02960-difluoroethylaminofuranone (BYI 02960-DFEAF) above the limit of quantitation (LOQ; 0.010 mg/L) were found in 3 out of 20 analysed samples during the sampling period in autumn 2010. The three occasions with BYI 02960-DFEAF residues >LOQ were the first three days of sampling (26 - 28 Sep 2010) and BYI 02960-DFEAF residues ranged between 0.023 mg/L (28 Sep 2010; highest value during the autumn sampling period) and 0.014 mg/L (27 Sep 2010; lowest value during the autumn sampling period). In all other samples from 2010, residues of BYI 02960-DFEAF were < LOQ (i.e. < 0.010 mg/L). Residues of BYI 02960 above the limit of quantitation (LOQ; 0.010 mg/L) were found in 7 out of 8 analysed samples during the sampling period in spring 2011, and the quantifiable residues ranged between 0.15 mg/L on the last sampling date in 2011 (09 Apr 2011; highest value during the spring sampling period) and 0.062 mg/L on 18 Mar 2011. Residues of BYI 02960-difluoroethylaminofuranone (BYI 02960-DFEAF), during the sampling period in spring 2011, were always (i.e. in 8 of 8 analysed samples) below the limit of quantitation (i.e. <LOQ; <0.010 mg/L).

B. Study design and methods

1. Experimental treatments

Location: The field site was located in the region Bas-Rhin, Alsace, France.

Crop: Winter OSR seeds, seed-treated with the insecticidal seed treatment BYI 02960 FS 480 G, were sown on a field plot in Alsace, France, in autumn 2010. The size of the test field plot was approximately 4.5 ha.

Before the actual sowing of the BYI 02960 FS 480 G-treated winter OSR-seeds, a spray application with the test item BYI 02960 SL 200 G was carried out at the same day on the bare soil of the field plot, followed by immediate mechanical soil incorporation into the upper 15-20 cm of the soil. The application rate of this spray application was 1.5 L product/ha (actually: 311 g a.s./ha).

The sowing rate was 6.89 kg seeds/ha.

After the end of winter OSR flowering in 2011, the winter OSR was destroyed.

Samples of guttation liquid were taken from the surface of several winter OSR plants and from at least 10 different locations across the test field. Droplets were collected with glass capillaries, and the guttation liquid was subsequently transferred to a micro test tube. On each sampling day, the sampling was conducted approximately at the same time of the day (in the morning).

Sampling of guttation liquid started on 26 Sep 2010 after the winter OSR plants had emerged and as soon as guttation was observed (BBCH 9-11). After the emergence of the plants and start of guttation, sampling was conducted daily on the first 6 days. After this period, approximately three samplings were performed per week. In total, 20 samplings were conducted during autumn 2010.

In 2011, sampling of guttation liquid was continued. The samplings started approximately 4 weeks before flowering (full flowering was reached in the middle of April). During this period, samplings followed a sporadic pattern, with 1 to 2 samplings per week. The last 4 samplings were conducted daily. Sampling stopped when the winter OSR reached BBCH 59-60 (yellow bud stage, first flowers open). In total, 8 samplings were conducted during spring 2011.

No minimum amount of guttation liquid to be collected per sampling date was specified. The time which was spent to collect guttation droplets from the surface of the plants did not exceed two hours per sampling date. If more than 0.5 g guttation liquid could be sampled on one sampling date, the sample was split in two sub-samples (A and B) with at least 0.5 g remaining in sub-sample A.

Verification of sowing rates: Quantities of the sown seeds were verified by comparison of the weight of the seeds in the seed hoppers at the start and end of sowing to calculate the actually sown quantities of seeds.

Spray application technique: The application of the spray solution was carried out with spraying equipment typical for commercial applications. The test item (BYI 02960 SL 200 G) was weighed in the laboratory. An appropriate amount of spray-tank solution was prepared immediately before each application and transported to the field site in the spraying device. After the spray application, the actually applied volume/amount of spray solution was determined by weighing the remaining spray solution.

The spray application was performed under the following conditions:

cropless soil (followed by immediate mechanical soil incorporation), just before sowing of BYI 02960-treated winter OSR seeds (BBCH 00) on the same day
air temperature less than 25 °C

average wind speed less than 3 m/s

Storage and Shipment: All collected samples were stored deep frozen (≤ -18°C) as soon as possible after sampling until residue analysis. All samples were shipped deep frozen from Niefern to the principal investigator for residue analysis Ralf Schoening, Bayer CropScience AG, Monheim, Germany. Storage and shipment conditions were recorded by use of a datalogger or min/max thermometer.
The principal investigator at Bayer CropScience AG in Monheim was responsible for determining the levels of residues of BYI 02960 and BYI 02960-difluoroethylaminofuranone (BYI 02960-DFEAF) in guttation liquid samples collected from winter OSR plants.

2. Observation and measurements
Samples of guttation liquid were taken from the surface of several winter OSR plants and from at least 10 different locations across the test field. Droplets were collected with glass capillaries, and the guttation liquid was subsequently transferred to a micro test tube. On each sampling day, the sampling was conducted approximately at the same time of the day (in the morning).
The growth stage (BBCH code) of the winter OSR plants was recorded on each day of sampling.
For each day of the sampling periods in autumn 2010 and spring 2011, weather data (temperature, relative air humidity and rainfall) was collected by a nearby weather station (non-GLP records).

All collected samples were stored deep frozen (≤ -18°C) as soon as possible after sampling until residue analysis.
Residue analysis of guttation liquid from winter OSR plants was performed by using High Performance Liquid Chromatography (HPLC), coupled with electrospray and tandem mass spectrometry (MS/MS) detection according to method 01206/M001 (BCS report number MR-10/037, R. Schöning, P. Köster, 2011-03-28). The Limit of Quantitation (LOQ) of BYI 02960 and BYI 02960-DFEAF, defined as the lowest validated fortification level, was 1 µg/kg for all matrices tested in the method (bees, pollen, honey/nectar, green plant material and flowers/blossoms), respectively. The Limit of Detection (LOD) of BYI 02960 and BYI 02960-DFEAF, for the matrices tested within the method, ranged from 0.1 to 0.2 µg/kg, respectively.
For the matrix guttation liquid, a full validation set was included in this study. The Limit of Quantitation (LOQ) of BYI 02960 and BYI 02960-DFEAF defined as the lowest validated fortification level was 10 µg/L for guttation liquid, respectively. The Limit of Detection (LOD) of BYI 02960 and BYI 02960-DFEAF was 1 µg/L for guttation liquid, respectively.

RESULTS AND DISCUSSION

Residues of BYI 02960 above the limit of quantitation (LOQ; 0.010 mg/L) were found in 20 out of 20 analysed samples during the sampling period in autumn 2010 and ranged between 21 mg/L on the first sampling date in 2010 (26 Sep 2010; highest value during the autumn sampling period) and 0.087 mg/L on 20 Oct 2010 (lowest value during the autumn sampling period); at the last sampling date in autumn 2010 (29 Oct 2010), the BYI 02960 concentration in guttation liquid accounted to 0.26 mg/L. Generally, residues of BYI 02960 from the spring declined by about two orders of magnitude relative to the fall sampling period.
Residues of BYI 02960-difluoroethylaminofuranone (BYI 02960-DFEAF) above the limit of quantitation (LOQ; 0.010 mg/L) were found in 3 out of 20 analysed samples during the sampling period in autumn 2010. The three occasions with BYI 02960-DFEAF residues >LOQ were the first three days of sampling (26 - 28 Sep 2010) and BYI 02960-DFEAF residues ranged between 0.023 mg/L (28 Sep 2010; highest value during the autumn sampling period) and 0.014 mg/L (27 Sep 2010; lowest value during the autumn sampling period). In all other samples from 2010, residues of BYI 02960-DFEAF were < LOQ (i.e. < 0.010 mg/L).
Residues of BYI 02960 above the limit of quantitation (LOQ; 0.010 mg/L) were found in 7 out of 8 analysed samples during the sampling period in spring 2011, and the quantifiable residues ranged between 0.15 mg/L on the last sampling date in 2011 (09 Apr 2011; highest value during the spring sampling period) and 0.062 mg/L on 18 Mar 2011.
Residues of BYI 02960-difluoroethylaminofuranone (BYI 02960-DFEAF), during the sampling period in spring 2011, were always (i.e. in 8 of 8 analysed samples) below the limit of quantitation (i.e. <LOQ; <0.010 mg/L).

Details of the analytical results as obtained by analysing samples of OSR guttation fluid are given in an Analytical Phase Report (Appendix A9 of the study report).

Table 10.4.5.5-1: Residues of BYI 02960 and BYI 02960-DFEAF in samples of guttation liquid

Sample		Origin	Date of sampling	Residue [mg/L]	
				BYI 02960 (min - max)	BYI 02960-DFEAF (min - max)
Guttation liquid	Winter-OSR seedlings/ plants, grown from BYI 02960 dressed seeds, sown in BYI 02960 treated soil		26 September 2010 - 29 October 2010	0.087 - 21.0	< LOQ - 0.023
			18 March 2011 -09 April 2011	< LOQ - 0.15	< LOQ

Residues of BYI 02960and its metabolite BYI 02960-DFEAF are given as a range of the minimum and maximum values as obtained throughout different time periods (several weeks in autumn / spring, respectively) during which the samples had been collected
BYI 02960-DFEAF = BYI 02960-difluoroethylaminofuranone (BCS-CC98193),

LOQ = Limit of Quantitation = 10 µg/L in guttation liquid (BYI 02960 and BYI 02960-DFEAF

B. Study Reliability and Discussion of Deficiencies

This study is considered fully reliable. No deficiency was noted.

Conclusion

A field study was conducted to determine residues of BYI 02960 in guttation liquid, collected from winter oil-seed rape (winter OSR), grown in BYI 02960-treated soil from seeds, seed-treated with BYI 02960 FS 480 G.

Residues of BYI 02960 above the limit of quantitation (LOQ; 0.010 mg/L) were found in 20 out of 20 analysed samples in autumn 2010 (quantifiable residues ranging from 21 mg/L to 0.087 mg/L). Generally, residues of BYI 02960 declined by about two orders of magnitude during the approximately 5 weeks lasting autumn sampling period.

Residues of BYI 02960 above the limit of quantitation (LOQ; 0.010 mg/L) were found in 7 out of 8 analysed samples in spring 2011; (quantifiable residues ranging from 0.15 mg/L to 0.062 mg/L).

Residues of the metabolite BYI 02960-DFEAF were < LOQ (i.e. < 0.010 mg/L) except for 3 out of 8 analysed samples (collected in the first three days of sampling) in autumn 2010 and for all samples (8 of 8) collected in spring 2011, respectively.

B.9.4.4 Risk assessment (IIIA 10.4.1)

Procedures for risk assessment were in agreement with the recommendations in the Guidance Document on Terrestrial Ecotoxicology Under Council Directive 91/414/EEC (Working Document Sanco/10329/2002 rev 2 final, 17 October 2002, referring to EPPO (EPPO 170 and EPPO 2002). EPPO 2002 was updated with EPPO 2010[9], an update focussing especially on systemic substances.

Exposure to honeybees is not relevant for the glasshouse use in lettuce (lettuce for food production needs no pollination therefore honeybees are not expected to be introduced in or be attracted to lettuce production in glasshouse).

Exposure is relevant for the field uses in hops and lettuce. The crops themselves are not attractive to honeybees for nectar and/or pollen collection. However, honey bees may be present in the field to forage on flowering weeds; bees foraging off-field may be exposed via spray drift. Furthermore, potential exposure routes are via honeydew, succeeding crops and guttation and other drinking water sources.

B.9.4.4.1 Acute toxicity data and first-tier acute risk assessment

Below the results of laboratory testing with honeybees are summarised.

Table B.9.4.4-01 Acute toxicity of technical BYI 02960 to honey bees in the laboratory

Test substance	Ecotoxicological Endpoint: LD_{50}		Reference
BYI 02960 (tech.)	oral 24 h oral 48 h contact 24 h contact 48 h contact 72 h contact 96 h	1.3 µg a.i./bee **1.2 µg a.i./bee** >200 µg a.i./bee >200 µg a.i./bee 158.4 µg a.i./bee **122.8 µg a.i./bee**	Schmitzer & Sekine (2008) KIIA 8.7.1/01
	Ecotoxicological Endpoint: NOED		
	oral contact	0.68 µg a.i./bee* 25 µg a.i./bee	

Bold values: Endpoints considered relevant for risk assessment

*The NOED for mortality is 0.68 µg a.i./bee. However, discoordinated movements and aparthy occurred at this and all higher dose rates. The $NOED_{oral}$ for sublethal effects is therefore set at 0.34 µg a.i./bee. The $NOED_{contact}$ is 25 µg a.i./bee also for sublethal effects.

[9] EPPO 2010: Environmental risk assessment scheme for plant protection products. Chapter 10: Honeybees. OEPP/EPPO, Bulletin OEPP/EPPO Bulletin 40, 323–331

Table B.9.4.4-02 Acute toxicity data of the formulated product BYI 02960 SL 200 G to honey bees in the laboratory

	Ecotoxicological Endpoint: NOED		
	contact	≥100 µg a.i./bee	

In the plant metabolism studies, a range of metabolites have been measured in the reproductive plant organs (flowers). The observed metabolites were tested in acute and chronic toxicity studies for potential effects on honey bees. Table B.9.4.4-04 provides an overview of the investigated metabolites, including the parent compound. Results of the acute toxicity studies are provided in Table B.9.4.4-05.

Table B.9.4.4-04 Overview table on names and synonyms of compounds addressed within the bee chapter

Abbreviation / Chemical code	Alternative name
BYI 02960	Flupyradifurone
BYI 02960-DFEAF	BYI 02960-difluoroethyl-amino-furanone
BYI 02960-OH	BYI 02960-hydroxy
DFA	Difluoroacetic acid
6-CNA	6-chloronicotinic acid
BYI 02960 -CHMP	6-chloropicolyl alcohol, 6-CPA

Bold values: Endpoints considered relevant for risk assessment

An indication of hazard (Hazard Quotient or HQ) can be derived according to the EPPO risk assessment scheme, by calculating the ratio between the single application rate (expressed in g/ha) and the lowest laboratory contact and oral LD50 (expressed in µg/bee).

HQ_O and HQ_C resp. = Application rate [g/ha] / LD50 oral or LD50 contact [µg/bee]

HQ values are calculated using data from the studies performed with technical material and the corresponding formulated product. HQ values higher than 50 indicate the need of higher tiered tests to clarify the actual risk to honey bees.

Table B.9.4.4-06 Hazard quotients for bees – oral exposure

Crop	Exposure route	LD_{50} [µg a.i./bee]	Application rate [g/ha]	Hazard quotient HQ_O	Trigger	Refined risk assessment
BYI 02960 SL 200						
Hops	oral	3.2	150	47	50	No
Lettuce	oral	3.2	125	39	50	No
off-field						
Hops	oral	3.2	150*0.1933	9.1	50	No
Lettuce	oral	3.2	125*0.0277	1.1	50	No
BYI 02960 (technical)						
Hops	oral	1.2	150	**125**	50	**Yes**
Lettuce	oral	1.2	125	**104**	50	**Yes**
off-field						
Hops	oral	1.2	150*0.1933	24	50	No
Lettuce	oral	1.2	125*0.0277	3.5	50	No

The hazard quotients for oral exposure calculated for BYI 02960 technical exceed the empirical trigger value for higher tier testing (HQ_O > 50) for both uses. Therefore, a refined risk assessment will be conducted, see below (higher tier semi-field and field studies).
Because a risk is indicated based on the full in-field dose, the off-field risk is also calculated. The default drift rates of the next section (non-target arthropods other than bees) are used to calculate the exposure that may occur on the off-field area. Based on these default drift rates and the trigger of 50, an off-field acute risk is not indicated.

Table B.9.4.4-07 Hazard quotients for bees – contact exposure

Crop	Exposure route	LD_{50} [µg a.i./bee]	Application rate [g/ha]	Hazard quotient HQ_O	Trigger	Refined risk assessment
BYI 02960 SL 200						
Hops	contact	15.7	150	9.6	50	No
Lettuce	contact	15.7	125	8.0	50	No
BYI 02960 (technical)						
Hops	contact	122.8	150	1.22	50	No
Lettuce	contact	122.8	125	1.02	50	No

The hazard quotient for contact exposure is below the empirical trigger value for higher tier testing (HQ_C <50) for both envisaged uses. Therefore, no unacceptable acute risk to bees is to be expected via the contact route of exposure.

Table B.9.4.4-04 shows that all relevant plant metabolites have a very low acute toxicity to honeybees (all LD50 values >100 µg a.i./bee). Therefore, the acute risk of these metabolites is low.

The bumble bee contact toxicity test does not indicate concern about higher sensitivity of bumble bees than honey bees.

B.9.4.4.2 Chronic toxicity data

There are currently no harmonised and ring tested test guidelines available to assess the chronic risk to adult honey bees. Nonetheless, there is some experience within the European honey bee testing community on conducting chronic studies in adult honey bees, by exposing honey bees orally to a treated 50% (w/v) sucrose solution as an exclusive food source for a period of 10 consecutive days by continuous and ad libitum feeding. Since the originally submitted chronic study with the a.s. was deemed unacceptable die to high control mortality and uncertainty about sublethal effects, the notifier performed a new chronic study with the a.s. Table B.9.4.4-08 provides an overview of the results obtained with parent BYI 02960 and its metabolites.

Table B.9.4.4-08 Chronic toxicity to adult honey bees in the laboratory

Test substance	Ecotoxicological Endpoint: NOEC / NOED		Reference
BYI 02960	NOEC (nominal) NOED (nominal)	26000 µg a.i./L 0.79 µg a.i./bee/day	Gladbach, Theis et al., 2013 KIIA 8.16.1/09
BYI 02960-DFEAF	NOEC (nominal) NOED (nominal)	≥ 10000 µg a.i./L ≥ 0.435 µg a.i./bee/day	Kling, 2012, KIIA 8.16.1/02
BYI 02960-OH	NOEC (nominal) NOED (nominal)	≥ 10000 µg a.i./L ≥ 0.420 µg a.i./bee/day	Kling, 2012, KIIA 8.16.1/03
DFA	NOEC (nominal) NOED (nominal)	≥ 10000 µg a.i./L ≥ 0.379 µg a.i./bee/day	Kling, 2012, KIIA 8.16.1/04
6-CNA	NOEC (nominal) NOED (nominal)	≥ 10000 µg a.i./L ≥ 0.418 µg a.i./bee/day	Kling, 2012, KIIA 8.16.1/05
BYI 02960-CHMP	NOEC (nominal) NOED (nominal)	≥ 10000 µg a.i./L ≥ 0.413 µg a.i./bee/day	Kling, 2012, KIIA 8.16.1/06

The table shows that all relevant plant metabolites show very low chronic toxicity to honeybees.

The a.s. has chronic mortality endpoints very close to the acute mortality endpoints, see Table B.9.4.4-09. Thus, the toxicity of the a.s. is not increased when the substance is taken in for several consecutive days; there is no concern about chronic/delayed toxicity with regard to mortality.

Table B.9.4.4-09 Comparison of acute and chronic endpoints for mortality in adult honey bees

	NOEDoral	$LD(D)_{50}$
Studies with technical grade active substance	[µg a.s./bee(/day)]	[µg a.s./bee(/day)]
Acute adult toxicitv studv (48 hours)	0.68	1.2
Chronic adult toxicitv studv (10 davs)	0.79	1.83

As explained above, the foliage residue toxicity study KIIIA 10.4.3/01 was not evaluated by RMS because guidance on how to perform, evaluate and use this study in the risk assessment is not available in EU.

Chronic toxicity of BYI 02960 to honey bee larvae
There are currently no harmonised and ring tested test guidelines available to assess the chronic risk to honey bee larvae. Nonetheless, there is experience in Europe within some laboratories on conducting chronic studies in honey bee larvae. A study has been performed with the active substance.

Table B.9.4.4-10 Chronic toxicity of BYI 02960 honey bee larvae in the laboratory

Test substance	Ecotoxicological Endpoint: NOEC / NOED		Reference
BYI 02960	NOEC (nominal) NOED (nominal)	≥ 10000 µg a.i./kg larval diet ≥ 0.44 µg a.i./bee larvae/day	Nikolakis *et al.*, 2010 KIIIA1 10.4.6.1/01

The chronic toxicity studies with the metabolites show no effects to adult honeybees at the highest tested dose of 10 mg/L diet. The chronic toxicity study with the a.s. shows no effects to honeybee larvae at the highest tested dose of 10 mg/kg diet. Only in the chronic toxicity study on adult honeybees with the a.s., which was performed at higher doses than the other studies, effects were seen. From this study, a NOEC of 26 mg a.i./L/ 0.79 µg a.i./bee/day could be derived. These endpoints could be used in risk calculations based on daily intake values for different castes of honeybees. This is discussed below.

B.9.4.4.3 Residue measurements in nectar and pollen and other matrices

B.9.4.4.3.1 Residue measurements in *Phacelia*

An overview of the measured residues of the a.s. and metabolite DFEAF in the semi-field trials on *Phacelia* in the different matrices was compiled by RMS in Tables B.9.4.4-11-16. In these studies, the first foliar spray applications was done just before flowering and the second foliar spray application was done during full flowering.

B.9.4.4.3.3 Residue measurements in nectar and pollen of other crops

Four supervised residue trials under semi-field conditions (studies KIIA 8.16.2/04 to /07) were submitted in which the residue levels in melon and tomato flowers, nectar (from combs or honey

stomachs) and pollen (from combs or forager honey or bumble bees) were studied. One trial in melon was performed in North-Carolina and studied either a drench or a double foliar application. Two trials in watermelon and one in tomato were performed in Spain and all studied a drench application. The location (for the trial in North Carolina) or the application method (for the drench trials) are less relevant for the GAP under evaluation. Therefore, the residue levels are not summarised in this section nor used in the risk assessment, but all results can be found in Tables B.9.4.2-16 and -17.

B.9.4.4.3.4 Residue measurements in guttation water

The flupyradifurone residue situation in guttation water was investigated in two field studies in winter oil seed rape (W-OSR) (KIIA 8.16.2/09 and /10, Rexer 2012c and d). The treated seeds in these studies were treated at a rate of nominally 10 g flupyradifurone a.s./kg and were sown at actual rates of 59 and 70 g flupyradifurone a.s./ha. The seeds were sown on field plots which were treated at the day of W-OSR-planting with nominally 300 g flupyradifurone a.s./ha (actually 310 and 311 g flupyradifurone a.s./ha), which was immediately incorporated down to a depth of 15 - 20 cm. Guttation fluid from the W-OSR seedlings were collected from the very first day onwards, at which the first guttation droplets occurred; this started at BBCH 9 - 11, which means at a crop stage with minimal dilution of residues due to plant growth and plant biomass.

The maximum residue level in guttation fluid in the two studies was measured at the very first days where guttation droplets occurred after emergence (actually 12 and 13 days after seed planting); thereafter, the concentrations of flupyradifurone decreased continuously.
In autumn, residues of BYI 02960 above the limit of quantitation (LOQ; 0.010 mg/L) were found in 20 out of 20 analysed samples in autumn 2010 (quantifiable residues ranging from 11 mg/L to 0.039 mg/L in one study and from 21 mg/L to 0.087 mg/L in the other study). Generally, residues of BYI 02960 declined by about two orders of magnitude during the approximately 5 weeks lasting autumn sampling period. In the following spring, residues of BYI 02960 above the LOQ were found in all or the majority of the analysed samples (quantifiable residues ranging from 0.21 mg/L to 0.014 mg/L or 0.15 mg/L to 0.062 mg/L).

In autumn, residues of the metabolite BYI 02960-DFEAF were < LOQ (i.e. < 0.010 mg/L) except for 2 out of 10 or 3 out of 8 analysed samples (collected in the first, (second) and third day of sampling; maximum residue 0.023 mg/L. In spring, all residues of the DFEAF-metabolite were < LOQ.

B.9.4.4.3.5 Residue measurements in soil

Residue measurements in soil were performed in some of the semi-field and field studies, to confirm the artificially incorporated background concentration in soil.

Table 9.4.4-25 Residues of BYI02960 in **soil**

Study	Application rate	DAA1	Residue BYI 02960	Residue BYI 02960-

			(µg/kg) mean (individual samples)	DFEAF (µg/kg) mean (individual samples)

KIIIA 10.4.5/01	1x 300 g a.s./ha (soil application). 10 g a.s./kg OSR seeds (seed treatment), 2x205 g a.s./ha (foliar spray)	0	75 (75)	not done
KIIIA 10.4.5/02	1x 300 g a.s./ha (soil application). 10.1 g a.s./kg OSR seeds (seed treatment), 2x205 g a.s./ha (foliar spray)	0	61 (61)	not done

B.9.4.4.4 Risk calculations for exposure via nectar and pollen

The envisaged use of BYI 02960 in hops is an application rate of 150 g a.i./ha, also during the flowering period of the crop. However, hop is a dioecious plant, with male and female flowers developing on separate plants. The harvested commodity in commercial hop cultivation is the female flower cluster. Male hop plants, which could theoretically offer honey bees pollen, are not cultivated in hop plantations – on the contrary: as any pollination of the female flowers (by male pollen) would significantly reduce hop quality, would significantly reduce the harvesting window and would significantly hamper the processing of the hop in breweries, hop plantations are entirely cultivated with female plants. Female flowers, however, do not offer honey bees nectar and pollen. As such, the commercial hop plantations themselves are not attractive to honey bees at any growth stage.

The envisaged use of BYI 02960 in lettuce accounts for an application rate of 125 g a.i./ha, during the development of harvestable, vegetative plant parts. Lettuce does not flower in commercial cultivation (except in seed production, which is not proposed here) and as such, honey bees are not attracted by the crop. Moreover, spray applications of BYI 02960 during flowering are excluded by the envisaged application window.

In conclusion, the crops themselves are not attractive to honeybees for nectar and/or pollen collection. However, weeds may be present in the field and these may flower. In general, the occurrence of weeds and especially flowering weeds in crop fields is not beneficial for growers, a.o. because these weeds will compete with the crop plants for resources. However, weed occurrence will depend on the crop and the individual farmer and may be MS specific. The presence of flowering weeds can

therefore not be excluded a priori. For hops especially, undergrowth vegetation is expected to be present. Therefore, the risk via nectar and pollen of flowering weeds should be addressed for the in-field situation.

A large dataset is available with residue measurements.
One semi-field study in Phacelia studied the residue levels after a twofold spray application of 200 g a.s./ha, one just before and one during flowering. Residue levels on pollen and nectar taken from foraging bees directly after the second spray application are high, but decrease quickly:
Phacelia pollen from forager bees one hour after spraying: ca. 65 mg/kg, decreasing within the first day to ca. 36 mg/kg (four hours after spraying). One day after spraying, a level of ca. 10 mg/kg is reached and this decreases within ten days to ca. 0.5 mg/kg.
Phacelia nectar from forager bees one hour after spraying: ca. 3 mg/kg, decreasing within the first day to ca. 1.4 mg/kg (four hours after spraying). One day after spraying, a level of ca. 0.8 mg/kg is reached and this decreases within ten days to ca. 0.04 mg/kg.
The residue levels in pollen and nectar in the hive (maximum ca. 10 mg/kg and 0.1 mg/kg, respectively) are much lower than the residue levels in pollen and nectar collected by forager bees, but they remain present for a longer time (24 days after spraying, the residue levels in pollen and nectar in the hive are ca. 2 mg/kg and 0.03 mg/kg, respectively). In two other semi-field trials, in which next to two foliar applications, also a soil application was used during sowing, residue levels were only measured on one timepoint but results are more or less in accordance with the results of the study with only foliar applications.

Two field trials in oilseed rape also studied residue levels in pollen and nectar taken from foraging bees. These study included two foliar applications and a seed treatment and furthermore had a background soil concentration.
The highest residue level in oilseed rape pollen from forager bees was found on the day of spraying: 21 mg/kg. The level decreased less rapidly than in the above Phacelia study (without seed treatment), reaching a level of ca. 1-2 mg/kg within ten days.
The highest residue level in oilseed rape nectar from forager bees was found three days after spraying: ca. 4 mg/kg. The level decreased to ca. 2 mg/kg within ten days.
The residue levels in pollen and nectar in the hive (maximum values of individual samples ca. 4 mg/kg and 1 mg/kg, respectively) are lower than the residue levels in pollen and nectar collected by forager bees. Hive residues were only measured on day 10 or day 23 after the last application and not earlier, so a direct comparison is difficult. Hive residues remain present for a longer time (23 days after spraying, the residue levels in pollen and nectar in the hive are maximum 1 mg/kg and 0.6 mg/kg, respectively; after 180 days, still 0.004 mg/kg is found in beebread).

In all the above studies, residue levels of metabolite DFEAF are much lower than those of the a.s. and decrease in a similar way.

It is difficult to determine a generic RUD value from these residue measurements, as the trials were performed with different application regimes and each trial had multiple applications. However, a general picture can be derived: directly after spraying, high levels of the a.s. can be found in nectar and pollen; residues in pollen are higher than those in nectar; residue levels in pollen and nectar in the hive seem to be lower than the residue levels in pollen and nectar collected by forager bees, but they remain present for a longer time; after six months, still traces of the a.s. can be found in the beebread; the residue levels of metabolite DFEAF are much lower than those of the a.s.

These residue levels could be used in exposure calculations, using daily intake values for nectar and pollen for different castes of bees. The exposure values could then be compared to the toxicity values derived above. If such an exercise is undertaken, it should be noted that the residue levels were determined in studies which used at least two foliar sprays with 200 g a.s./ha each, while the proposed uses in hops and lettuce have only a single application, at 150 and 125 g a.s./ha, respectively, and furthermore are not attractive to bees themselves. However, at the moment there is no harmonised method available to calculate these exposure levels and especially the corresponding risk. Furthermore, it is not necessary to perform these lower tier calculations, as a large number of higher tier effect studies is available. Please see the section below (higher tier toxicity data and risk assessment).

B.9.4.4.5 Higher tier toxicity data and risk assessment for exposure via nectar and pollen

Six independent semi-field (gauze tunnel) studies were submitted, where BYI 02960 formulations were applied to the highly bee attractive surrogate crop Phacelia tanacetifolia with honey bees actively foraging on the crop (i.e. during bee flight). The studies are summarised in Table B.9.4.4-26. One of these studies was not accepted (except for residue analysis) because of an unequal colony set-up.

The studies were all performed by two different laboratories. Differences between these laboratories were reflected in the report for the use of statistics and preparation of tables or figures. RMS has prepared stacked figures in those cases that figures were missing. In that way the interpretation of the results was more convenient as comparisons between studies are made easier and more transparent.

According to the notifier, " the results of all of the six semi-field (tunnel) studies under forced and as such worst-case exposure conditions consistently did not show any adverse effects on mortality, foraging activity, behaviour, brood-, food- and population development or on overall colony vitality". They state that "overall, the laboratory database shows that BYI 02960 does not exhibit delayed or chronic effects, either in adult bees or in honey bee larvae. BYI 02960 metabolites are virtually non-toxic to honey bees and there is no indication that BYI 02960 metabolites are of any higher toxicity regarding potentially delayed or chronic effects than the parent compound. These laboratory findings have been consistently confirmed by in total six independent semi-field tunnel studies in the highly bee attractive surrogate crop Phacelia tanacetifolia. As such, it can be concluded that BYI 02960 can be applied at foliar application rates of up to and including 200 g a.i./ha, even to bee-attractive, full-flowering crops during honey bees actively foraging, without adverse effects on honey bees, honey bee brood and honey bee colonies."

RMS however notes the following:

- Study 01 and /02 were not performed under GLP and are therefore less reliable. However, they represent the two lowest exposure situations in the dataset and are therefore less important for the overall conclusion.

- Endpoints in this type of semi-field study are interrelated. For instance mortality of bees outside the hive will depend on flight intensity. When flight intensity is reduced, mortality in the tunnel might be reduced as well as fewer bees are foraging. This was indeed the case in the studies where reduction of flight intensity was observed. Flight intensity was significantly reduced in studies 10.4.7/03-06; reduction was observed for three to seven days.

- Significant effects on flight intensity are present in studies 10.4.6/3 to 10.4.7/6. In studies 10.4.6/1 and /2 however, flight intensity was not evaluated statistically. Differences between studies may therefore be biased by the performing laboratory. However, based on visual inspection of the data RMS agrees that studies 10.4.6/1 and/2 do not suggest an effect on foraging activity.

- Repellence of flupyradifurone leads to decreased flight intensity. In that way bees will minimize exposure of the hive to flupyradifurone. In the studies in which reduced flight intensity was seen, effects on other endpoints were not clearly visible.

- Of course, a short-term reduction of flight intensity can be an effective way to reduce exposure and possibly related risk for honey bee colonies. It can only be seen as an acceptable effect if it does not lead to effects on bee colonies in the longer term from a shortage of food. This was not apparent in the semi-field studies (brood development, food storage area and colony strength comparable to control in all studies) but effects on these parameters can potentially be masked by the small colony size and confined conditions..

- Exposure in the tunnel was on average 12 days. Longer exposure is not feasible as the foraging opportunities within a tunnel are too limited. It was evident in most studies that there was a reduction of the colony strength during confinement in the tunnel. After placement of the hives in the open field, colonies started to grow again. Any effects of the active substance can therefore be masked by the stronger effect of confinement to the tunnel. Moreover, due to natural variability between the hives it is extremely difficult to evaluate differences between treatment and control.

- Reduction of flight intensity and effects on behaviour were observed in those studies that were worst case for number of applications and timing of the applications (those ranked by RMS as 1, 2, 3 and 4).

- So far guidance has not been developed for the interpretation of changes of endpoints on brood development. Since the endpoints are interrelated, possible effects are difficult to disentangle. Evaluation of these endpoints is difficult without a clear perspective on normal brood development.

- It is not yet clear if and how results can be assessed statistically. Indeed, in these 6 studies, statistical assessment has not been performed on endpoints of brood development.

- Confined conditions may result in possible stress on bees which may result in a natural reduction of brood activity when bees are kept inside tunnels for longer periods. In these studies reductions of brood activity are indeed often observed during confinement to the tunnels.

- According to the EFSA opinion on bees, it is not possible to assess pollen and nectar storage and hive weight development due to the small size of the colony; therefore, it is difficult to assess potential effects on honey production (i.e. a potential protection goal) when adverse

effects are observed on other parameters. As smaller sizes of colonies are used in semi-field studies, the interpretation of impacts on full size colonies will be difficult and the possibility to translate adverse effects on a small colony to a full size colony seems limited. Due to confined conditions, the small size of the colony and the high turnover rate of nectar and pollen in the tunnels, it is not possible to assess hive weight development and direct potential effects on honey production.

Based on the above, the semi-field studies alone are not considered sufficient proof that the risk to bees is acceptable. However, also two field studies and one long-term colony feeding study were submitted. These are summarised in Table B.9.4.4-27.

Development of food storage aria	Increase pollen and nectar stores similar to control	Increase pollen and nectar stores similar to control	Increase pollen and nectar stores similar to control
Behaviour	intensive cleaning behaviour and locomotion problems in small fraction of bees of treated colonies on day after 2nd foliar application	no treatment-related effects	
Remark			The low number of replicates (especially in the control, with only three remaining replicates) and the apparent variation within the treatment groups in mortality of bees/drones/immature stages make it difficult to draw conclusions on the effect of the treatment. What can be concluded is that, under the specific circumstances of this study, the different treatments of the test substance do not lead to an adverse effect in one of the observed parameters (or the combination

			of adverse effects of the different parameters) to such an extent, that it led to the collapse of one or more colonies.
Statistics for mortality and flight intensity	no	no	yes
Statistics for brood and food storage	no	no	yes

Thus, these studies confirm the results of the semi-field studies.

In the two field studies on oil seed rape, no adverse effects on honey bees were seen during the exposure period nor during the observation period which included overwintering. The only treatment-related effects were a short-term (two days) reduction on flight intensity in both studies and some behavioural anomalies in a small fraction of bees for one day in one of the two studies. These effects apparently did not lead to direct or delayed effects on survival or wellbeing of the colonies as compared to the control colonies. Exposure in the field studies was confirmed with residue measurements in nectar and pollen both from forager bees and from hive matrices.

Also, a long-term feeding study was submitted in which colonies were forced to feed on up to 10 mg/kg diet for seven weeks. This is clearly a worst-case exposure for the GAPs of the semi-field and field studies (2x 200 g a.s./ha foliar spray and in some cases also background soil concentration included). In these trials, the initial concentration in pollen and nectar taken from forager bees could be above 10 mg/kg on the first days, but this quickly decreased to below 10 mg/kg. In the hives, the concentration in pollen or nectar never exceeded a maximum value of 10 mg/kg and also decreased to much below that level soon. This study had some shortcomings but it can be concluded that a 7-week exposure to 10mg flupyradifurone/kg diet does not lead to collapse of a colony, including overwintering.

The overall data package shows that the spraying of 2x 200 g a.s./ha on a bee-attractive crop 1x before and 1x during full flowering and active foraging of honey bees does not result in adverse acute or long-term (including overwintering) effects on honey bee colonies.

This data package covers the proposed uses in the non-attractive crops lettuce and hops with application rates of 1x125 and 1x150 g a.s./ha, respectively. For these crops, the main concern is via flowering weeds especially in the hop plantations. The above studies in highly attractive crops indicate that a low risk is expected from these uses via nectar and pollen of flowering weeds.

Expert discussion in Pesticide Peer Review meeting 124 (December 2014):

The RMS concluded that the data sets indicate that overall no adverse acute or long-term effects (including over-wintering evaluation) were indicated for a spray of 2 x 200 g a.s./ha on bee attractive crops during full flowering and active foraging (1 application prior to flowering and 1 application during flowering). The experts at the meeting agreed with the conclusion of the RMS noting that some slight transient treatment related effects may have been observed.

B.9.4.4.6 Risk assessment for other exposure routes

B.9.4.4.6.1 Exposure via honeydew

Aphids are expected to be more sensitive to flupyradifurone than bees because they are target pest species. If they are indeed more sensitive, buildup of honeydew at a level that can harm honeybees is not expected. However, this needs to be confirmed with data. The notifier has submitted dose-response studies with aphids (KIIIA1 6.1.1) . However, actual LD50 values were not found in the dose-response studies and the doses are expressed in g a.s./ha; therefore they are not useful for a comparison with the toxicity to honeybees. The notifier also submitted an LD50-study with the green peach aphid (all these data are summarised under B.9.9.2). The raw data of the LD50-study with the green peach aphid need to be submitted before conclusions can be drawn about the usefulness of the study. However, based on the conclusion above that the risk via direct overspray and via nectar and pollen of highly attractive flowering crops is acceptable, a high risk via honeydew (directly oversprayed or produced (much) later by aphids) is not expected either.

Expert discussion in Pesticide Peer Review meeting 124 (December 2014):

The RMS included a consideration of the risk via insect honey dew in the DAR. The RMS considers that the higher tier studies were sufficient to cover the risk to honey bees via this route of exposure. The experts agreed with the conclusions of the RMS that this route of exposure was addressed.

B.9.4.4.6.2 Exposure via guttation and other water sources

The relevance of exposure via guttation droplets and other water sources for honey bee risk assessment is not yet clear. The risk via guttation droplets is generally estimated to be highest from droplets on young seedlings grown from treated seeds. The applicant submitted two studies in which the residue level in young oil seed rape seedlings, sown in soil with a background concentration covering the PECplateau of the proposed uses, was measured. A highest level of 21 mg/L was found (initial level, quickly declining). This is comparable to the NOEC-value from the chronic honey bee laboratory study with technical flupyradifurone (10-d feeding of 26 mg/kg in highly bee attractive sugar solution). Therefore, a high risk via guttation is not indicated. Based on the conclusion above (see section higher tier toxicity data and risk assessment) that the risk via direct overspray and via nectar and pollen of highly attractive flowering crops is acceptable, a high risk via other water sources (e.g. puddles, surface water) is not expected either.

B.9.4.4.6.3 Exposure via succeeding crops

In order to account for potential side-effects on honey bees from a potential carry-over of soil-borne flupyradifurone residues into potentially bee-attractive, succeeding flowering cops, a worst-case soil-plateau concentration was established in two out of four semi-field studies in Phacelia tanacetifolia as well as in both long term honey bee health field studies in W-OSR. In all of these four studies which evaluated potential side-effects on honey bees, nominally 300 g flupyradifurone a.s./ha was applied onto the soil at the day of crop planting, to be immediately incorporated down to depth of 20 cm to establish a worst-case, non-aged flupyradifurone soil plateau concentration within the root zone of the planted, bee-attractive flowering crop. The analytically determined soil concentration in these four studies was in the range of 36 - 76 µg flupyradifurone a.s./kg soil.

These analytically determined soil concentrations can be compared to the soil plateau concentration that has been calculated in the fate section. The PECplateau for lettuce of 0.016 mg/kg (over 20 cm) is clearly covered. For hops, the reported PECplateau is 0.080 mg/kg, but this is calculated over 5 cm for perennial crops without tillage. In case of succeeding crops other than hops, tillage will take place and it can be assumed that the soil concentration will be spread over 20 cm, leading to a soil concentration of 0.020 mg/kg. Thus, risk via succeeding crops of the use in hops is also covered with the effect semi-field and field studies.

STUDY IIA, 8.8.1.1/01

Characteristics

reference	:	Jans D. (2010a)	species	:	*Aphidius rhopalosiphi*
type of study	:	Laboratory toxicity study	exposure duration	:	2 days
year of execution	:	2009	nominal dose	:	0.5, 1.1, 2.2, 4.7, 10, 20, 40, 80 and 160 g a.s./ha
GLP statement	:	Yes	dosing method	:	Dry residues on glass plates
guideline	:	Mead-Briggs *et al*. (2000), Candolfi *et al* (2001)	acceptability	:	Acceptable
test substance	:	BYI 02960 SL 200 G (200 g/L SL formulation), batch 2009-001253	LR50	:	<0.5 g a.s./ha
a.s. content	:	17.0 % w/w (199.8 g/L) BYI 02960			

Methods

The effect of fresh residues of BYI 02960 SL 200 G (200 g/L SL formulation, 17.0 % w/w (199.8 g/L) BYI 02960) on survival of the parasitic wasp *Aphidius rhopalosiphi*, confined under laboratory conditions over laboratory-treated glass plates, was determined.

Two trials 1 and 2 were performed. Treatment rates in trial 1 were 10, 20, 40, 80 and 160 g a.s./ha. Trial 2 was performed at lower treatment rates since in trial 1 100% mortality was observed at all treated rates within 24 hours. Treatment rates in trial 2 were 0.5, 1.1, 2.2, 4.7 and 10 g a.s./ha. Treatments with BYI 02960 SL 200 G and a positive control (dimethoate, 0.04 g a.s./ha) were tested in 200 L spray solution/ha against water-treated controls. Laboratory treated glass plates were allowed to dry for 1 hour and incorporated into test units (4/treatment), forming floor and ceiling respectively. Fifteen adult wasps (<48 hours old) were added to each test unit. The test units were kept in a controlled environment room until study end. Mortality was assessed during 48 hours.

Results

Control mortality was 1.7% after 24 hours in trial 1 and 0% after 48 hours in trial 2. Mortality was 100% at all treated rates of BYI 02960 SL 200 G in trial 1 and 2, except for the 0.5 g a.s./ha treatment in trial 2 (85% mortality and corrected mortality). The LR50 is <0.5 g a.s./ha. The reference substance gave the expected response in both tests (100% mortality within 24 or 48 hours).

Conclusion

LR50 <0.5 g a.s./ha.

Guidelines & Limitations

The study is acceptable.

STUDY IIA, 8.8.1.1/02

Characteristics

reference	:	Jans D. (2010b)	species	:	*Typhlodromus pyri*
type of study	:	Laboratory toxicity study	exposure duration	:	7 days
year of execution	:	2009	nominal dose	:	2, 4, 9, 19 and 40 g a.s./ha
GLP statement	:	Yes	dosing method	:	Dry residues on glass plates
guideline	:	Blümel *et al*. (2000) , Candolfi *et al* (2001)	acceptability	:	Acceptable
test substance	:	BYI 02960 SL 200 G (200 g/L SL formulation), batch 2009-001253	LR50	:	17 g a.s./ha
a.s. content	:	17.0 % w/w (199.8 g/L) BYI 02960			

Methods

The effect of fresh residues of BYI 02960 SL 200 G (200 g/L SL formulation, 17.0 % w/w (199.8 g/L) BYI 02960) on survival of the predatory mite *Typhlodromus pyri*, confined under laboratory conditions over laboratory-treated glass plates, was determined.

Treatments with BYI 02960 SL 200 G at 2, 4, 9, 19 and 40 g a.s./ha and a positive control (dimethoate, 4 g a.s./ha) were tested in 200 L spray solution/ha against water-treated controls. Laboratory treated glass plates were allowed to dry for 1 hour and incorporated into test units (5 per treatment, 5 for the control) to form the floor. A layer of sticky material provided an exposure area of each test unit into which twenty protonymphs were added. The test units were kept in a controlled environment room until study end. Survival was assessed over a 7-day period.

Results

Results are summarised in Table B.9.5.1-01. The LR50 (Probit analysis) was 17 g a.s./ha (95% CI 13-21 g a.s./ha). The reference substance gave the expected response (80% mortality within 7 days).

Table B.9.5.1-02 Effects of BYI 02960 SL 200 G on *Typhlodromus pyri* under laboratory conditions

Treatment	Dose (g a.s./ha)	Mortality (%) after 7 days	Corrected mortality (%)[(A)]
Water control	-	4	-
BYI 02960 SL 200 G	2	10	6.3

BYI 02960 SL 200 G	9	28*	25.0
BYI 02960 SL 200 G	19	52*	50.0
BYI 02960 SL 200 G	40	90*	89.6

* statistically significant difference from control at 5% level.
(A) According to Abbott formula

Conclusion

LR50 17 g a.s./ha.

Guidelines & Limitations

The study is acceptable.

STUDY IIIA, 10.5.2/01

Characteristics

reference	:	Jans D. (2010e)	species	:	*Aphidius rhopalosiphi*
type of study	:	Extended laboratory toxicity study	exposure duration	:	2 days
year of execution	:	2010	nominal dose	:	0.5, 0.89, 1.58, 2.81 and 5.0 g a.s./ha
GLP statement	:	Yes	dosing method	:	Dry residues on barley seedlings
guideline	:	Mead-Briggs *et al*. (2000), Mead-Briggs *et al*. (draft 2006), Candolfi *et al* (2001)	acceptability	:	Acceptable
test substance	:	BYI 02960 SL 200 (200 g/L SL formulation), batch 2009-001253	LR50	:	2.02 g a.s./ha
a.s. content	:	17.0 % w/w (199.8 g/L) BYI 02960	ER50	:	>0.89 g a.s./ha; <1.58 g a.s./ha

Methods

The effect of fresh residues of BYI 02960 SL 200 (200 g/L SL formulation, 17.0 % w/w (199.8 g/L) BYI 02960) on survival and reproduction of the parasitic wasp *Aphidius rhopalosiphi*, confined under laboratory conditions over laboratory-sprayed barley seedlings, was determined.

Treatment rates were 0.5, 0.89, 1.58, 2.81 and 5.0 g a.s./ha. Treatments with BYI 02960 SL 200 and a positive control (dimethoate, 3.0 g a.s./ha) were tested in 400 L spray solution/ha against water-treated controls. Potted 5-day old barley plants (6 replicate pots per treatment), that had been sprayed with 10% fructose solution one hour earlier, were treated with the test substance using a calibrated laboratory sprayer. The residue was allowed to dry for about 1 hour, the plants were enclosed within acrylic cylinders and five female <48 h old wasps were added to each replicate. The test units were kept in a controlled environment room until study end. Assessments of repellence were made during the first 3 hours and wasp mortality was assessed during 48 hours. Thereafter, 15 surviving healthy females of the control and the three lowest treatment rates were removed and individually confined over untreated aphid-infested barley plants for 24 hours. The wasps were then removed and the plants were left for a further 11 days before the number of aphid mummies was recorded.

Results

No repellent effect of the test item was observed. Control mortality was 3.3% after 48 hours. At 0.5, 0.89, 1.58, 2.81 and 5.0 g a.s./ha, respectively, mortality after 48 hours was 0%, 13.3%, 40.0%, 70.0% and 90.0%. The LR50 (Probit analysis) was 2.02 (95% CI 1.61-2.55) g a.s./ha. At 0.5, 0.89 and 1.58 g a.s./ha, respectively, reduction of reproduction was -6.4%, -2.9% and 57.7%, respectively (reproduction not tested at higher concentrations). The effect on reproduction at 1.58 g a.s./ha was statistically significant at the 5% uncertainty level. The ER50 was not reported but is between 0.89 and 1.58 g a.s./ha. The reference substance gave the expected response (100% mortality within 48 hours).

Conclusion

LR50 2.02 g a.s./ha, ER50 >0.89 g a.s./ha.

Guidelines & Limitations

The study is acceptable.

STUDY IIIA, 10.5.2/02

Characteristics

reference	:	Jans D. (2010f)	species	:	*Typhlodromus pyri*
type of study	:	Extended laboratory toxicity study	exposure duration	:	14 days
year of execution	:	2010	nominal dose	:	15, 32, 67, 142 and 300 g a.s./ha
GLP statement	:	Yes	dosing method	:	Dry residues on bean leaf discs
guideline	:	Blümel *et al*. (2000), Candolfi *et al* (2001)	acceptability	:	Acceptable
test substance	:	BYI 02960 SL 200 (200 g/L SL formulation), batch 2009-001253	LR50		177 g a.s./ha
a.s. content	:	17.0 % w/w (199.8 g/L) BYI 02960	ER50		>142 g a.s./ha

Methods

The effect of fresh residues of BYI 02960 SL 200 (200 g/L SL formulation, 17.0 % w/w (199.8 g/L) BYI 02960) on survival and reproduction of the predatory mite *Typhlodromus pyri*, confined under laboratory conditions over laboratory-treated bean leaf discs, was determined.

Treatments with BYI 02960 SL 200 at 15, 32, 67, 142 and 300 g a.s./ha and a positive control (Dimethoate EC 400 g/L, 400 g/L dimethoate, 40 g a.s./ha) were tested in 200 L spray solution/ha against water-treated controls. Bean leaf discs were treated with the test substance using a calibrated laboratory sprayer and allowed to dry for about 1 hour prior to incorporation into test units (5 per treatment and for the control) to form the floor. A thin layer of surrounding insect trap glue provided an exposure area within each test unit into which twenty protonymphs were added. The test units were kept in a controlled environment room until study end. Survival was assessed over a 7-day period. Fecundity assessments were carried out in the control and all treatments except the highest during a second week in the same treated test units.

Results

Results are summarised in Table B.9.5.1-02. The LR50 (Probit analysis) was 177 g a.s./ha (95% CI 151-205 g a.s./ha). The ER50 is >142 g a.s./ha. The reference substance gave the expected response (100% mortality within 7 days).

Table B.9.5.1-02 Effects of BYI 02960 SL 200 on *Typhlodromus pyri* under extended laboratory conditions

Treatment	Dose (g a.s./ha)	Mortality (%) after 7 days	Corrected mortality (%)[(A)]	Eggs/ female	Reduction of reproduction (%)
Water control	-	13.0	-	4.5	-
BYI 02960 SL 200	15	12.0	-1.1	4.3	6.0
BYI 02960 SL 200	32	9.0	-4.6	4.5	0.6
BYI 02960 SL 200	67	19.0	6.9	4.3	5.1
BYI 02960 SL 200	142	46.0*	37.9	4.8	-6.8[(C)]
BYI 02960 SL 200	300	79.0*	75.9	n.t.[(B)]	-

* statistically significant difference from control at 5% level.
(A) According to Abbott formula
(B) n.t. = not tested.
(C) Negative value represents increase relative to control, hence no adverse effect.

Conclusion

LR50 177 g a.s./ha, ER50 >142 g a.s./ha.

Guidelines & Limitations

The study is acceptable.

STUDY IIIA, 10.5.2/03

Characteristics

Reference	:	Jans D. (2010g)	Species	:	*Coccinella septempunctata*
Type of study	:	Extended laboratory toxicity study	Exposure duration	:	13-17 days
Year of execution	:	2009-2010	Nominal dose		Trial 1: 8, 17, 35, 72 and 150 g a.s./ha; Trial 2: 100, 160, 250, 380 and 600 g a.s./ha
GLP statement	:	Yes	Dosing method	:	Dry residues on detached bean leaves
Guideline	:	Schmuck *et al.* (2000)	Acceptability	:	Acceptable
Test substance	:	BYI 02960 SL 200 (200 g/L SL formulation), batch 2009-001253	LR50	:	273.9 g a.s./ha
a.s. content	:	17.0 % w/w (199.8 g/L) BYI 02960	Reproduction		No effects up to 250 g a.s./ha

Methods

The effect of freshly dried residues of BYI 02960 SL 200 (200 g/L SL formulation, 17.0 % w/w (199.8 g/L) BYI 02960) on survival and reproduction of the ladybird *Coccinella septempunctata*, confined under laboratory conditions over laboratory-treated bean leaf discs, was determined.

Two trials 1 and 2 were performed, since in the first trial no effects were found up to the highest test dose of 150 g a.s./ha. Treatments with BYI 02960 SL 200 at 8, 17, 35, 72 and 150 g a.s./ha (trial 1) or 100, 160, 250, 380 and 600 g a.s./ha (trial 2) and a positive control (Dimethoate EC 400 g/L, a.s. dimethoate, 12 g a.s./ha) were tested in 200 L water/ha against water-treated controls. Detached bean leaves (*Phaseolus vulgaris*) were treated with the test substance using a calibrated laboratory sprayer and allowed to dry for about 1 hour. After application a disc was cut out of the bean leaf which was incorporated into a test unit (40 units per treatment and for the control) to form the floor (treated side up). In each unit one 4-day old larva was individually confined. The test units were kept in a controlled environment room until study end. Assessments of mortality were made up to adulthood (duration of exposure phase 13 days for trial 1 and 17 days for trial 2). Surviving ladybirds were transferred to untreated reproduction containers and egg counts were initiated one week after the first eggs in the control could be observed. Eggs were counted during two weeks, and hatching success was determined.

Results

Mortality and reproduction data are summarised in the Tables below. The toxic reference gave the expected response. The LR50 (Probit analysis) was 273.9 (95% CI 185.9-330.8) g a.s./ha. The IOBC guideline by Candolfi *et al* (2000) states that the assessment of reproduction is of a qualitative nature,

and that there is no effect on reproduction if the number of fertile eggs per viable female per days exceeds 2.0, which was the case for all tested BYI 02960 SL 200 treatments up to 250 g a.s./ha.

Conclusion

LR50 273.9 g a.s./ha; no effect on reproduction up to 250 g a.s./ha.

Guidelines and limitations

The study is acceptable.

STUDY IIIA, 10.5.2/04

Characteristics

reference	:	Jans D. (2010h)	species	:	*Aleochara bilineata*
type of study	:	Extended laboratory study	exposure duration	:	28 days
year of execution	:	2009-2010	nominal dose	:	Trial 1: 10, 21, 45, 95 and 200 g a.s./ha; Trial 2: 300 g a.s./ha
GLP statement	:	Yes	exposure method	:	Solution of test substance in water was sprayed on soil
Guideline	:	Grimm *et al.* (2000), Candolfi *et al* (2001)	acceptability	:	Acceptable
test substance	:	BYI 02960 SL 200 (200 g/L SL formulation), batch 2009-001253	ER50	:	>300 g a.s./ha
a.s content	:	17.0 % w/w (199.8 g/L) BYI 02960			

Methods

The effect of BYI 02960 SL 200 (200 g/L SL formulation, 17.0 % w/w (199.8 g/L) BYI 02960) on the reproductive capacity of the rove beetle *Aleochara bilineata*, exposed under extended laboratory conditions to fresh residues on natural soil, was determined.

Two trials 1 and 2 were performed, since in the first trial no effects were found up to the highest test rate of 200 g a.s./ha. Test units were plastic vessels (24 x 24 x 10.5 cm), which were covered with gauze, and contained LUFA 2.1 soil (4-5.5 cm high) moistened to 35% of WHC (0.74-0.81% oc, pH 5.1, 86.3-86.6% particles >0.063 mm, characterised (DIN) as sand or silty sand). The test substance was dissolved in water and sprayed on the soil using a calibrated laboratory sprayer in 400 L water/ha. The treatment rates for BYI 02960 SL 200 were 10, 21, 45, 95 and 200 g a.s./ha (trial 1) and 300 g a.s./ha (trial 2). The toxic standard was Dimethoate EC 400 g/L, sprayed onto the soil at a rate of 788.8 g a.s./ha in 400 L water/ha. The control was left untreated. Twenty adult beetles (10 females and 10 males) were introduced into each treated test unit immediately after application (4 replicate units per treatment). Yellow mealworm larvae were placed on the soil surface as a food source about 1 hour after application and then every 2-3 days afterwards. Seven, 14 and 21 days after application, 500 *Delia antiqua* pupae were placed into each test unit for parasitisation. The test units were kept in a controlled environment room until study end. Soil water losses were replaced every 2-3 days. Four weeks after application, the beetles were removed from the exposure units and discarded. Five weeks after application, the pupae were sieved out of the soil and transferred into untreated hatching cages, which were maintained to assess hatching rate until the hatching rate in the controls had fallen below 2 beetles per replicate per day.

Results

The reported results on reproduction are summarised in the tables below. The number of emerged beetles in the water treated control satisfied the criterion (≥400 per replicate) in Grimm *et al* (IOBC, 2000). The reference substance gave the expected response. As there were no statistically significant effects on reproduction at any test dose, the ER50 is >300 g a.s./ha.

Table B.9.5.1-06 Effects of BYI 02960 SL 200 on *reproduction of A. bilineata* under extended laboratory conditions (trial 2)

Test item		BYI 02960 SL 200 (g/L)		
Test organism		*Aleochara bilineata*		
Exposure on:		Spray deposits on sandy soil (LUFA 2.1)		
		Reproductive capacity		
Treatment	g as/ha	Hatched beetles per introduced female (number)	Red. rel. to control [%]	P-Value(#)
Control	0	71.2		
Test item	300	62.0	13.0	0.322 n.sign.
Reference item	788.8	21.5	69.8	
ER_{50} > 300 g as/ha # one-way ANOVA, Williams test (one-sided) n.sign. not significant				

Conclusion

ER50 >300 g a.s./ha (natural soil with 0.74-0.81% organic carbon).

Guidelines and limitations

The study is acceptable. The age of the beetles at test initiation was not reported, but the reproductive performance of the control was acceptable and the response of the reference product confirmed the sensitivity of the test organisms.

STUDY IIIA, 10.5.3/01

Characteristics

reference	:	Jans D. (2010i)	species	:	*Aphidius rhopalosiphi*
type of study	:	Extended laboratory toxicity study (aged residues)	exposure duration	:	2 days
year of execution	:	2010	nominal dose	:	2 x 250 g a.s./ha (10 days interval)
GLP statement	:	Yes	dosing method	:	Semi-field aged residues on maize seedlings
guideline	:	Mead-Briggs *et al*. (2000), Mead-Briggs *et al*. (2009), Candolfi *et al* (2001)	acceptability	:	Acceptable
test substance	:	BYI 02960 SL 200 G (200 g/L SL formulation), batch 2009-001253	Endpoint	:	No adverse effects on survival and reproduction following exposure to 56-day aged residues
a.s. content	:	17.0 % w/w (199.8 g/L) BYI 02960			

Methods

Maize seedlings were treated with BYI 02960 SL 200 G (200 g/L SL formulation, 17.0 % w/w (199.8 g/L) BYI 02960) and aged up to 56 days under semi-field conditions. The effect of residues of BYI 02960 SL 200 G on survival and reproduction of the parasitic wasp *Aphidius rhopalosiphi*, confined under laboratory conditions over leaves cut from the treated maize seedlings, was determined.

The study was conducted in Höchst, Frankfurt am Main, Germany. The treatment regime for BYI 02960 SL 200 G was two times 250 g a.s./ha in 400 L water/ha (T1 and T2), with a treatment interval of 10 days (treatment dates 07 and 17 May, 2010). The study included a positive control (Dimethoate EC 400 g/L, 3.0 g a.s./ha) in 400 L water/ha, and water-treated controls. Treatments with BYI 02960 SL 200 G were applied under semi-field conditions to potted maize plants using a plot sprayer. Aging of the spray residues on the potted maize plants took place under natural semi-field conditions with rain protection (Plexi-glass, UV permeable). The temperature ranged from 5.2 to 39.3°C and the relative humidity from 20.8 to 99.9% during the aging time of the maize plants. Bioassays were performed with pieces of maize leaf (about 25 cm long) taken from treated plants at 0, 14, 28, 42, 49 and 56 days after the second treatment. One piece of leaf was transplanted in a pot. A wet piece of paper was wrapped around the leaf part which was put in the pot bottom, and the pot was filled with quartz sand up to 0.5 - 2 cm below the upper pot rim, so that the leaf stood in an upright position. Finally the leaf was sprayed with a 10% fructose solution and left to dry. Then the pot was filled with quartz sand completely to the pot rim. The pots were placed on a water absorbent mat to allow the pots to soak up water. Each pot with one treated maize leaf was enclosed within a clear polyacrylic cylinder, into which five female <48 h old wasps were introduced. The top of the cylinder was closed with a fine mesh gauze. Each bioassay was performed with 6 replicate pots. The test units were kept in a controlled environment room until study end. Assessments of repellence were made during the first 3 hours and wasp mortality was assessed during 48 hours. During the 4th, 5th and 6th bioassay, 15 surviving females of the control and the BYI 02960 SL 200 G treatment were removed and individually confined over untreated aphid-infested barley plants for 24 hours. The wasps were then removed and the plants were left for a further 11 days before the number of aphid mummies was recorded.

The reference item was applied under semi-field conditions only at the second application day of the test item. In the second to the sixth bioassay the reference item was freshly applied in the laboratory using a calibrated laboratory sprayer on detached leaves taken from untreated maize plants, which had been stored till then under outdoor conditions.

Results

The results are summarised in the Table below. The reference substance gave the expected response in all bioassays. Validity criteria of Mead-Briggs *et al.* (2009) were satisfied: <10% control mortality, ≥5 mummies per control female, no more than 2 control wasps producing zero reproduction.

A repellent effect of the test item was observed up to 28 days after the second treatment. A statistically significant effect on survival was noted up to 49 days after the 2nd treatment, and a statistically significant effect on reproduction was recorded at 42 days after treatment. No more statistically significant or biologically relevant effect on survival and reproduction) occurred by day 56 after the 2nd treatment.

Conclusion

Two treatments T1 and T2 of maize plants in spring (7 and 17 May) in Germany at 250 g a.s./ha with 10 days interval: statistically significant effects on survival of *A. rhopalosphi* up to 49 days after T2, and on reproduction at 42 days after T2; no effects by day 56 after T2.

Guidelines & Limitations

The study is acceptable.

STUDY IIIA, 10.5.3/02

Characteristics

reference	:	Schwarz A. (2010)	species	:	*Orius laevigatus*
type of study	:	Extended laboratory toxicity study (aged residues)	exposure duration	:	8-15 days
year of execution	:	2010	nominal dose	:	2 x 250 g a.s./ha (10 days interval)

GLP statement	:	Yes	dosing method	:	Semi-field aged residues on apple trees
guideline	:	Bakker et al. (2000)	acceptability	:	Acceptable
test substance	:	BYI 02960 SL 200 G (200 g/L SL formulation), batch 2009-001067	Endpoint	:	No adverse effects on survival and reproduction following exposure to 42-day aged residues
a.s. content	:	201.0 g/L BYI 02960			

Methods

Apple trees were treated with BYI 02960 SL 200 G (200 g/L SL formulation, 201.0 g/L BYI 02960) and aged up to 42 days under semi-field and field conditions. The effect of residues of BYI 02960 SL 200 G on survival and reproduction of the predatory bug *Orius laevigatus*, confined under laboratory conditions over leaves cut from treated apple trees, was determined.

The study was conducted in Rossdorf, Germany. The treatment regime for BYI 02960 SL 200 G was two times 250 g a.s./ha in 400 L water/ha (T1 and T2), with a treatment interval of 10 days (treatment dates 31 May and 10 June, 2010). The study included a positive control (Perfekthion, 414.8 g/L dimethoate, 37 g a.s./ha in 400 L water/ha for treatment of apple trees in the field, 10 g a.s./ha in 200 L water/ha for treatment of detached apple leaves in the laboratory), and water-treated controls. Treatments with BYI 02960 SL 200 G were applied under semi-field conditions to apple trees using a plot sprayer (BBCH 17-27 and 17-31 at 1st and 2nd application, respectively). Aging of the spray residues on the apple trees took place under natural semi-field conditions with rain protection (transparent, light permeable roof) up to 19 days after T2. Thereafter, the roof was removed, but on two more occasions (2 and 1 day, respectively), the plants were protected against rain due to forecast of heavy rain. The temperature ranged from 7 to 37°C and the relative humidity from 34 to 100% during the aging time of the apple trees. Bioassays were performed with detached leaves taken from treated trees at 0, 14, 28 and 42 days after the second treatment.

Leaf discs were cut from detached leaves from treated trees and incorporated into test units, forming the floor (treated side upwards). One 2nd instar nymph (4-5 days old) was added to each replicate unit. There were 50 replicates for each treatment, the control and the reference product. Food (*Ephestia* eggs) was added to the exposure units at least twice weekly. The test units were kept in a controlled environment room until study end. Assessments of mortality were made up to adulthood (during 8-15 days). During the 28DAT and 42DAT bioassay, when at least 80% of the control test organisms had developed into adults, all surviving males and females of a treatment were transferred to an untreated mating vessel. After mating, mated females were placed individually in untreated oviposition units consisting of a cylinder placed on a leaf disc from a leaf from an untreated bean plant, and the eggs were counted after 2 days and incubated to determine hatching success. The females were then transferred to new untreated oviposition units and after 2 days the eggs were again counted and incubated to determine hatching success.

The reference item was applied under semi-field conditions only at the second application day of the test item. In the second to the fourth bioassay, the reference item was freshly applied in the laboratory using a calibrated laboratory sprayer on detached leaves taken from untreated apple trees.

Results

The results are summarised in the Table below. The reference substance gave the expected response in all bioassays. Validity criteria of Bakker *et al.* (2000) were satisfied in all bioassays: <25% control mortality, ≥2 eggs per control female per day and <5 bugs producing zero values, >70% hatching rate.

A statistically significant effect on survival was noted up to 28 days after the 2nd treatment, and no statistically significant effects on reproduction were recorded at 28 and 42 days after treatment. No more statistically significant or biologically relevant effect on survival and reproduction) occurred by day 42 after the 2nd treatment.

(A) According to Abbot.
(B) Note: negative value, hence no adverse effect.

Conclusion

Two treatments T1 and T2 of apple trees in spring (31 May and 10 June) in Germany at 250 g a.s./ha with 10 days interval: statistically significant effects on survival of *O. laevigatus* up to 28 days after T2, no effects on reproduction at 28 and 42 days after T2; no adverse effects by day 42 after T2.

Guidelines & Limitations

The study is acceptable.

B.9.5.2 Semi-field and field studies (IIA 8.8.2, IIIA 10.5.3 and IIIA 10.5.4)

IIIA 10.5.4/01

Data requirement 5.2

Applicant to submit more comprehensive study summary of the two studies Aldershof S. & Bakker F. (2012). Furthermore the present table B.9.5.2-02 should be presented in a readable version. More detailed information will be necessary to understand the visualised results and especially the data standing behind it (e.g. validity criterion).

See also expert consultation 5(60).

See reporting table 5(58)

During the EU evaluation of Flupyradifurone SL 200 (BYI 02960 SL 200) EFSA set a data requirement for the applicant to provide a better readable extended version of the study summaries that were provided in the DAR with an improved quality of the included graphs and tables (see above). The applicant provided these. The sections of the applicant's summary that provide additional information and/or graphs/figures of improved graphical quality are added to the RMS' summary below.

Characteristics

reference	:	Aldershof S. & Bakker F. (2012a)	test organism	:	Field populations of arthropods

GLP statement	:	Yes	dosing method	:	Sprayed on grassland
guideline	:	IOBC (Hassan, 1992), Brown (1998), Candolfi *et al.* (2000, 2001), De Jong *et al.* (2010)	acceptability	:	Acceptable
test substance	:	BYI 02960 SL 200, batch 2010-001067	conclusion	:	NOAER population, effect class 2: 21 g a.s./ha NOER community: 21 g a.s./ha NOER population: 5.1 g a.s./ha
a.s. content	:	201.0 g a.s./L (17.1% w/w)			

Objective

This field study was designed to assess the potential adverse effects on Non-Target Arthropods (NTA) in off-crop habitats that might occur at various distances from a treated area for current and future use pattern of the test item. The study was set up to enable an assessment of community- and population level ecotoxicological standards, in particular the NOER (No Observed Effect Rate), the NOEAER and the LOEAER (No and Lowest Observed Ecologically Adverse Effect Rate, respectively).

Methods

The effect of BYI 02960 SL 200 (201 g/L BYI 02960) on non-target arthropod populations was investigated in Renkum (The Netherlands) under field conditions after 1 spray application on grassland at dose levels of 0.51, 1.7, 5.1 and 21 g a.s./ha on 30 June 2010, with water control and reference product (Karate Zeon, a.s. lambda cyhalothrin, 40 g a.s./ha), using a design to determine the NOER, NOEAER and LOEAER.

Test material

Test item:	BYI 02960 SL 200
Specification No.:	102000021884-01
Type:	Formulated product (soluble (liquid) concentrate)
Chemical state and description:	Clear brown liquid
Batch No.:	2010-001067
Sample description:	TOX 08907-00
Nominal content of active ingredient:	BYI 02960: 200 g/L
Analytical content of active ingredient:	BYI 02960: 17.1% w/w, 201.0 g/L according to certificate of analysis
Density:	1.175 g/mL at 20°C
Stability of test compound:	Approved until 14.06.2012, when stored at 25 ± 5°C
Reference item:	Karate Zeon (lambda-cyhalothrin)
Batch No.:	BSN902273
MITOX ID	20100625FB01
Nominal content of active ingredient:	Lambda-cyhalothrin: 100 g/L (9.5%)
Stability of test compound:	Approved until June 2012
Controls:	Water
In-life dates	June 27 to August 30, 2010
Location:	3 km north of the village Renkum, 10 km west of the village Arnhem in the Netherlands.
Field description:	The meadow was located in an agricultural landscape (meadows, low crops, some bushes). The field was delimited on the western side by a road, on the north- and eastern side by a hedgerow and meadows, on the south side by a dirt road and meadows.

Trial lay out and treatment

Prior to trial lay out, the test site had been uncultivated grassland with low agricultural input (occasional mowing for hay production). The site was surrounded by agricultural fields. For approximately 20 years prior to the test no pesticides or herbicides were used on the test field, and during three years before the start of the study no mowing was performed. The soil had pH 4.5 and 7.1% organic matter (reported particle size distribution was incorrect, soil class was not reported).

On the test site, 24 plots (24 m x 24 m each) were established in a checkerboard design, such that treatment plots alternated with untreated plots, and no treatment plots were directly adjacent to one another. The BYI 02960 SL 200 treatments, the water control and the reference product were each assigned to four replicate plots, arranged in a randomised block design.

Figure NL-01: Plot layout

Applications were made in 200 L water/ha on 30 June 2010, using a calibrated lift-mounted sprayer with 2 booms (total length 12 m). Spray deposit distribution during application was checked with water-sensitive papers at 2 locations in the test field and found to be adequate. In addition, water-sensitive papers were placed next to a treated plot on 2 locations, to monitor possible spray drift, these papers

did not show any contact with spray solution. The actual rate was confirmed to be within 7.3% of target by measuring the remaining spray liquid after applications of each plot.

Arthropod sampling

The soil-surface and plant-dwelling arthropod communities were sampled just before application (0-1 days before treatment), and 1, 2, 4 and 8 weeks after application (last sampling on 25 August 2010). On each sampling occasion, soil and surface dwelling arthropods were sampled using pitfall traps (10 per plot, 3-5 day sampling period), small, low and highly mobile plant inhabiting arthopods were collected using suction sampling, and mites and other low mobile small plant inhabiting arthropods were collected using weed sampling (weeds were cut off just above the soil surface from two 0.25 m^2 subplots of each plot) followed by Berlese-Tullgren extraction. Sampling was confined to the centre of each plot; pitfalls were placed in a central area of approximately 2 x 2 m around the plot centre and suction and weed sampling was done outside this central area. Arthropods were identified to the lowest possible taxonomic level.

Environmental conditions / irrigation

Climatic data were recorded on a weather station 8 km away from the test site. On the application day all treatments were applied during dry and calm weather conditions. No rainfall was recorded up to 10 days after treatment, when 29.3 mm fell. Total rainfall during the experimental period (2 months) was 267 mm.

Calculations and statistical analysis

<u>Evaluation at the community level (multivariate statistics)</u>

Data evaluation was done separately for the different sample types, and additionally with a dataset based on data from all sample types pooled. Final conclusions were based on results obtained from analyses of the pooled dataset.

Community level effects on non-target arthropods were examined using multivariate analysis techniques. The ordination technique used was Principal Response Curve method (PRC) developed by Van den Brink *et al.* (1996) and van den Brink and ter Braak (1999). The arthropod community data gathered in this study were analyzed using redundancy analysis. Data were log transformed (2*natural log of densities +1) prior to analysis. To assess the significance of differences between treatment groups and the control on each sampling moment separately, Monte Carlo permutation tests were performed per sampling date.

<u>Evaluation of separate taxa (univariate statistics)</u>

Only taxa that occurred at densities above 10 (total number of individuals in the sum of all water control treatments per sampling date) were considered. If taxonomically relevant, taxa were analyzed pooled if densities of individual taxa were too low for evaluation. Abbott's formula was used to express treatment effects relative to the control. The statistical significance of among treatment differences in

population density was determined separately for all time points using the nonparametric Mann-Whitney U test.

To reduce noise, taxa with Coefficient of Variation (CV) exceeding 1.4 (i.e. 140%) on more than three sampling moments were not used for effect evaluations. In addition, taxa with very unequal starting populations among treatments were excluded from evaluations. Taxa excluded from univariate evaluations were also excluded from the multivariate datasets. Taxa with CV exceeding 1.2 or 1.4 on several sampling moments were removed from the datasets used for multivariate analyses. As far as could be assessed, data did not indicate that these taxa that were excluded from analyses were adversely affected by the test item treatments.

Results of statistical analyses obtained from multivariate and univariate evaluations were in principle considered at an alpha level of 5%. However, for the evaluation of treatment related trends, statistical significances at an alpha level of 10% were considered in the context of graphical analysis of the results and if appropriate included by the reviewer in effect classification decisions.

Effects were classified according to De Jong *et al.* (2010). Different effect classes are listed below. For this study with a total post-application sampling period of two months only effect classes 1, 2, 3 and 8 are applicable. According to De Jong *et al.* (2010), recovery should be demonstrated on two consecutive sampling moments. Due to the 4 week interval between the last two sampling moments this would result in a very conservative effect classification. Effect class 3 was therefore subdivided in class 3a (no longer statistically significant on the last two sampling dates) and class 3b (no longer statistically significant on the last sampling date).

Table B.9.5.2-01 / Table NL-01 Effect classes according to De Jong *et al.* (2010)

Effect class	Description	Criteria
1	Effects could not be demonstrated (NOER)	• No (statistically significant) effects observed as a result of the treatment • Observed differences between treatment and controls show no clear causal relationship
2	Slight and transient effects	• Quantitatively restricted response of one or a few taxa and only observed on one sampling occasion
3	Pronounced short term effects; recovery within two months after first application	• Clear response of taxa, but full recovery within two months after the first application • Effects observed at two or more sampling instances
4	Pronounced effects; recovery within four months after first application	• Clear response of taxa, effects last longer than two months but full recovery within four months after the first application • Effects observed at two or more sampling instances
5	Pronounced effects; recovery within eight months after first application	• Clear response of taxa, effects last longer than four months but full recovery within eight months after the first application • Effects observed at two or more sampling instances
6	Pronounced effects; full recovery one year after first application	• Clear response of taxa, effects last longer than eight months but full recovery within one year after first application • Effects observed at two or more sampling instances
7	Pronounced effects; full recovery more than one year after first application	• Clear response of taxa, effects last longer than twelve months after the first application but full recovery found within the study period • Effects observed at two or more sampling instances
8	Pronounced effects; no recovery within the study period	• Clear response of taxa, no recovery within the duration of the study • Effects observed at two or more sampling instances

Note: For this study (see text), effect class 3 was subdivided in class 3a (no longer statistically significant on the last two sampling dates) and class 3b (no longer statistically significant on the last sampling date).

Results

Power analysis

For a rough estimation of the overall power of the univariate tests, Abbott values and P-values obtained from comparisons with the control and the toxic reference (Mann Whitney-U test) were presented in scatter plots. The minimum detection level for alpha= 0.05 was approximately 50% in the dataset including all sample types (used for final evaluations).

Arthropod species composition and abundance

Arthropod taxa with sufficiently high numbers for univariate analysis and acceptable CV (see before) were:

- *Acari*: 34 taxa, 8 of which were analysed (*Tydeoidea*; *Phytoseiid* female mites (mainly of the species *Graminaseius graminis* and *Typhlodromus kerkirae)*; other *Gamasida*; *Cunaxidae*; phytophagous *Tetranychidae*; *Tarsonemidae*; *Oribatida*).
- *Araneae*: *Lycosidae* (predominantly adult *Pardosa*); crab spider *Xysticus*; *Gnaphosidae*; *Phrurolithus* (*Clubionidae*); two taxa of the family *Linyphiidae*; juvenile *Araneidae*; *Phalangida*.
- *Coleoptera*: mainly *Carabidae* (*Amara*, *Harpalus*, *Poecilus*, *Pterostichus* and *Trechus*, other adult *Carabidae*) and *Staphylinidae* (*Aleocharinae*, *Staphilininae*, *Tachyporinae*, *Xantholininae*, other

Staphilinidae), and a few plant feeding taxa (*Elateridae*, *Alticinae* (*Chrysomelidae*), *Apion* (*Curculionidae*), other *Curculionidae*).

This list was compared by the reviewer to Table 4 of De Jong et al. (2010), which gives an overview of taxa which should be present in off-field studies in sufficient numbers to allow univariate analyses with a sufficient power to allow for a comparison with the relevant regulatory threshold. The guidance states: “This overview is considered generally applicable to field studies in Europe. When certain taxa are lacking, this does not mean that the study is unreliable per se, but the evaluator should be triggered to ask questions about the reasons for the lack of certain taxa, and it should be argued in the study report why these taxa were not sampled, or why they are lacking. The other way around, under local conditions for some taxa a more precise level than indicated in Table 4 would be of importance. When this is known, these taxa could be included in the study.”

This list was compared by the reviewer to Table 4 of De Jong et al. (2010), which gives an overview of taxa which should be present in off-field studies in sufficient numbers to allow univariate analyses with a sufficient power to allow for a comparison with the relevant regulatory threshold. The guidance states: “This overview is considered generally applicable to field studies in Europe. When certain taxa are lacking, this does not mean that the study is unreliable per se, but the evaluator should be triggered to ask questions about the reasons for the lack of certain taxa, and it should be argued in the study report why these taxa were not sampled, or why they are lacking. The other way around, under local conditions for some taxa a more precise level than indicated in Table 4 would be of importance. When this is known, these taxa could be included in the study.”

The Coleopteran taxa Coccinellidae and Lathridiidae, Lepidoptera, Orthoptera, and the Aranean taxa Thomisidae were not present in this study. However, all of these except for Coccinellidae were present in the other field study (see below). Both field studies are taken into account in the risk assessment. Furthermore, several other Coleopteran taxa are present in the current study and Coccinellidae are represented in a first tier (laboratory) study, in which they were not very sensitive. Therefore, the study is considered sufficiently representative for the off-field environment.

Altogether, a total of 72 taxa were sufficiently abundant to be subjected to population level evaluations. Multivariate analyses showed that before application, arthropod species composition and abundance was rather similar in all plots. This was deduced from the fact that all sample scores were

plotted relatively close together. No clustering per block or per treatment could be detected. The test field was considered suitable for the study.

Reference product

Multivariate analysis showed that the reference treatment induced immediate and persistent (at least 4 weeks) adverse effects on the arthropod fauna sampled in grasslands. On three consecutive post-application sampling moments the response was statistically significant (see Figure B.9.5.2-01 / Figure NL-03). Univariate analysis showed that many taxa were adversely and statistically significantly affected by the reference item treatment (see Table B.9.5.2-02 / Table NL-03). The validity criterion for the reference treatment was clearly met (at least 50% effect on at least one sample date for at least 10% of the taxa evaluated; De Jong *et al.*, 2010). No recovery was seen for several taxa in the positive reference treatment, indicating that for the experimental period chosen, the plot size was adequate to demonstrate persistent treatment related effects. The response of the reference treatment confirmed the validity of the study.

Figure NL-02: Proportion of Abbott values above 50% in the reference treatment. X-axis indicates sampling moments (weeks after application)

Community responses

The results for community response (pooled data from all sampling methods) are summarised in Figure B.9.5.2-01 / Figure NL-03 (first ordination axis). The second ordination axis was not statistically significant for any of the test item rates and the percentage of variation due to treatment and captured by the first axis (23.3%) was high compared to the percentage captured by the second axis (9.9%), hence the overall community response is well described by the PRC from the first ordination axis. Based on pooled data, treatment with the insecticide BYI 02960 SL 200 in an off-field grassland habitat did not lead to statistically significant effects on prevailing arthropod communities at any of the rates tested up to 21 g a.s./ha. Examination of community responses obtained from separate datasets

did not reveal any treatment related adverse effect on arthropod communities either~~(data not shown in this summary)~~.

Figure B.9.5.2-01 / Figure NL-03 Principal Response Curve (first ordination axis)
Test- and reference items were analyzed separately but for comparison plotted in one graph. PRC analyses comprised data from weed- (W), pitfall- (P) and suction (S) samples. Encircled data points are statistically significant (Monte-Carlo Permutation test, alpha = 0.05). Test item dose rates are in g a.s./ha.

Reported evaluation of population responses

At rates up to and including 5.1 g a.s./ha, on single sampling moments statistically significant differences compared to the control were observed for several taxa, but no consistent trend in time or relation to the dose rate was found, and these observations are therefore considered to be unrelated

to treatment. For few taxa a statistically significant reduction compared to the control was seen one or two weeks after application in the highest BYI 02960 SL 200 rate of 21 g a.s./ha.

At 21 g a.s./ha, the statistically significant reductions of the mite taxon Cunaxidae 2 weeks after treatment and of the Hymenoptera taxa Alysiinae and other Braconidae one week after treatment were considered to be treatment related adverse effects, followed however by fast recovery. The statistically significant reductions of juvenile Miridae (Heteroptera taxon) one week after treatment were considered to be unrelated to the test item treatment since at the time the reduction occurred densities were low and declining, and relative differences in densities between treatment plots were not consistent in time. The statistically significant reductions of Xantholininae (Coleoptera) 2 weeks after treatment were not likely to be related to the treatment since there was no clear dose related response on any of the sampling moments, and densities in the highest test item rate were lowest before application took place. The author of the report did not comment on the statistically significant reduction of Chilopoda 2 weeks after treatment.

The author of the report drew the following conclusions:

- BYI 02960 SL 200 applied at a rate of 21 g a.s./ha is the community NOER (No Observed Effect Rate), effect class 1.
- The predatory mite Cunaxidae and the hymenopteran parasitoid Braconidae were adversely affected on one sampling moment only shortly after application in the highest test rate. Both populations recovered within the next sampling moment one or two weeks later. BYI 02960 SL 200 applied at 21 g a.s./ha (effect class 2), is therefore classified as the population NOEAER (no observed ecologically adverse effect rate).

Evaluation by reviewer

The reported conclusions for Cunaxidae, Alysiinae and other Braconidae are acceptable. Figures B.9.5.2-02 to -04 / NL-04 to -06 show that recovery indeed occurs quickly. The Y-axis shows the number of arthropods per treatment (total of all plots per treatment), on a log-scale.

Figure B.9.5.2-02 / Figure NL-04Effects on Cunaxidae (Prostigmata, Acari) [Weed samples]

Figure B.9.5.2-03 / Figure NL-05 Effects on Alysiinae (Braconidae, Hymenoptera) [Suction samples]

Figure B.9.5.2-04 / Figure NL-06 Effects on other Braconidae (Hymenoptera) [Suction samples]

The effects on Xantholininae, juvenile Miridae and Chilopoda are graphically displayed in Figure B.9.5.2-05 to –07 / Figure NL-07 to NL-09.

After 2 weeks, statistically significant reductions of 62% of Xantholininae were recorded at 5.1 and 21 g a.s./ha, respectively, and a weak dose-effect relationship is present. However, before and after the 2-week sampling there is no dose-effect relationship at all (therefore the statistically significant reduction after 4 weeks at 1.7 g a.s./ha is not considered treatment related), and in addition there were reductions of 56% (p=0.24) and 81% (p=0.091) at 5.1 and 21 g a.s./ha, respectively, at the pre-test sampling. The conclusion of the author (effect on Xantholininae after 2 weeks not likely to be related to the treatment) is supported.

Figure B.9.5.2-05 / Figure NL-07 Effects on Xantholininae (Staphylinidae, Coleoptera) [Pitfall samples]

Because of the strongly declining populations in all treatments (including the control), it is not unlikely that the statistically significant reduction of juvenile Myridae of 80% relative to the control at 21 g a.s./ha one week after treatment is unrelated to the test item treatment. This is supported by the fact that at the 2-week and 4-week sampling the populations of juvenile Myridae at 21 g a.s./ha were highest of all treatment and the control, and that there is no dose-response relation after one week; in fact, the second highest dose rate of 5.1 g a.s./ha has comparable individuals to the control while the lowest dose rate of 0.51 g a.s./ha has the second lowest number of individuals). The conclusion of the author (effect on juvenile Myridae unrelated to the treatment) is supported.

Figure B.9.5.2-06 / Figure NL-08 Effects on juvenile Miridae (Heteroptera) [Suction samples]

Chilopoda were collected in relatively low numbers from pitfall traps. A statistically significant reduction of 84% relative to the control ($p < 0.05$) was recorded one week after treatment at 5.1 g a.s./ha, and of 78% ($p < 0.1$) after 1 week and of 67% ($p < 0.05$) after 2 weeks at 21 g a.s./ha. However, during the pre-test sampling the numbers of Chilopoda were already lower than those of the control at 5.1 and 21 g a.s./ha (88% and 50%, respectively). Inspection of Figure B.9.5.2-04 / Figure NL-09 shows that at 21 g a.s./ha, the development of the population of Chilopoda is comparable to that of the control throughout the test period (the curves are essentially parallel), and that the pre-test difference was maintained throughout the study. The statistically significant reduction of Chilopoda after 2 weeks at 21 g a.s./ha is not likely to be a treatment related effect.

Figure B.9.5.2-07 / Figure NL-09: Effects on Chilopoda [Pitfall samples]

Hence, the reported evaluation of the study results is considered to be acceptable.

Conclusion

BYI 02960 SL 200, single application to grassland on 30 June 2010 in The Netherlands: community NOER 21 g a.s./ha, effect class 1; population NOEAER 21 g a.s./ha (effect class 2).
Some taxa showed a statistically significant increase. These could potentially result from indirect effects.

Guidelines & Limitations

Comments were incorporated in the above summary. The study is acceptable. The actual concentration of BYI 02960 in the spray solution was not confirmed by chemical analysis. However, the test material was a certified product, and since it was a Soluble Concentrate (SL), inhomogeneity in the spray tank is not likely to occur.

IIIA 10.5.4/02

Data requirement 5.2 Applicant to submit more comprehensive study summary of the two studies Aldershof S. &

Bakker F. (2012). Furthermore the present table B.9.5.2-02 should be presented in a readable version. More detailed information will be necessary to understand the visualised results and especially the data standing behind it (e.g. validity criterion).

See also expert consultation 5(60).

See reporting table 5(58)

During the EU evaluation of Flupyradifurone SL 200 (BYI 02960 SL 200) EFSA set a data requirement for the applicant to provide a better readable extended version of the study summaries that were provided in the DAR with an improved quality of the included graphs and tables (see above). The applicant provided these. The sections of the applicant's summary that provide additional information and/or graphs/figures of improved graphical quality are added to the RMS' summary below.

Objective

This field study was designed to assess the potential adverse effects on Non-Target Arthropods (NTA) in off-crop habitats that might occur at various distances from a treated area for current and future use patterns of the test item. By analogy to regulatory studies in e.g. aquatic environments the study was set up to enable an assessment of community- and population level ecotoxicological standards, in particular the NOER (No Observed Effect Rate), the NOEAER and the LOEAER (No and Lowest Observed Ecologically Adverse Effect Rate, respectively).

Methods

The effect of BYI 02960 SL 200 (201 g/L BYI 02960) on non-target arthropod populations was investigated in Sainte Maure de Peyriac, Lot et Garonne, South-France, under field conditions after 1

spray application on grassland at dose levels of 0.51, 1.7, 5.1 and 21 g a.s./ha on 20 July 2010, with water control and reference product (Karate Zeon, a.s. lambda cyhalothrin, 40 g a.s./ha), using a design to determine the NOER, NOEAER and LOEAER.

Test material

Test item:	BYI 02960 SL 200
Specification No.:	102000021884-01
Type:	Formulated product (soluble (liquid) concentrate)
Chemical state and description:	Clear brown liquid
Batch No.:	2010-001067
Sample description:	TOX 08907-00
Nominal content of active ingredient:	BYI 02960: 200 g/L
Analytical content of active ingredient:	BYI 02960: 17.1% w/w, 201.0 g/L according to certificate of analysis
Density:	1.175 g/mL at 20°C
Stability of test compound:	Approved until 14.06.2012, when stored at 25 ± 5°C
Reference item:	Karate Zeon (lambda-cyhalothrin)
Batch No.:	BSN9H2472
MITOX ID	20100505JR01
Nominal content of active ingredient:	Lambda-cyhalothrin: 100 g/L (9.5%)
Stability of test compound:	Approved until May 2011
Controls:	Water
In-life dates	13 July until 14 September 2010
Location:	The field was situated 1.5 km east of the village Sainte Maure de Peyriac, Lot et Garonne (47), in the South-West of France.
Field description:	The meadow was delimited on the northeastern side by a road, on the northwestern side by a house and gardens, at the southeast and southwest side by vinyards. It was gently sloping down towards the southwest.

Trial lay out and treatment

Prior to trial lay out, the test site had been uncultivated grassland with little agricultural input (occasional mowing for hay production). The site was surrounded by agricultural fields. For >5 years prior to the test no pesticides or herbicides were used on the test field. In January 2010, a low dose of fertiliser was applied on the field. Three months before the start of the study the field was mown (no mowing was performed during the study period). The soil had pH 6.1 and 4.1% organic matter (reported particle size distribution was incorrect, soil class was not reported). *Festuca pratensis* (meadow fescue) and *Trifolium pratense* (red clover) were the dominant plant species.

On the test site, plots (22 m x 22 m each) were established in a checkerboard design, such that treatment plots alternated with untreated plots, and no treatment plots were directly adjacent to one another. The BYI 02960 SL 200 treatments, the water control and the reference product were each assigned to four replicate plots, arranged in a randomised block design.

Figure SWF-01: Plot layout

Applications were made in 200 L water/ha on 20 July 2010, using a calibrated tractor-mounted sprayer with 2 booms (total length 7.5 m). Spray deposit distribution during application was checked with water-sensitive papers at 1 location in the test field and found to be adequate. In addition, water-sensitive papers were placed next to a treated plot to monitor possible spray drift, these papers did not

show any contact with spray solution. The actual rate was confirmed to be within 5.4% of target by measuring the remaining spray liquid after applications of each plot.

Arthropod sampling

The soil-surface and plant-dwelling arthropod communities were sampled just before application (3-6 days before treatment), and 1, 2, 4 and 8 weeks after application (last sampling on 14 September 2010). On each sampling occasion, soil and surface dwelling arthropods were sampled using pitfall traps (10 per plot, 4-7 day sampling period), small, low and highly mobile plant inhabiting arthropods were collected using suction sampling, and mites and other low mobile small plant inhabiting arthropods were collected using weed sampling (weeds were cut off just above the soil surface from two 0.25 m^2 subplots of each plot) followed by Berlese-Tullgren extraction. Sampling was confined to the centre of each plot; pitfalls were placed in a central area of approximately 2 x 2 m around the plot centre and suction and weed sampling was done outside this central area. Arthropods were identified to the lowest possible taxonomic level.

Environmental conditions / irrigation

Climatic data were recorded on a weather station <4 km away from the test site. On the application day all treatments were applied during dry and calm weather conditions. No rainfall was recorded on the day of application (1.2 and 16.4 mm on 1 and 2 days after application, respectively, no more rain up to day 12 after application).

Calculations and statistical analysis

<u>Evaluation at the community level (multivariate statistics)</u>

Data evaluation was done separately for the different sample types, and additionally with a dataset based on data from all sample types pooled. Final conclusions were based on results obtained from analyses of the pooled dataset.

Community level effects on non-target arthropods were examined using multivariate analysis techniques. The ordination technique used was Principal Response Curve method (PRC) developed by van den Brink *et al.* (1996) and van den Brink and ter Braak (1999). The arthropod community data gathered in this study were analyzed using redundancy analysis. Data were log transformed (2*natural log of densities +1) prior to analysis. To assess the significance of differences between treatment groups and the control on each sampling moment separately, Monte Carlo permutation tests were performed per sampling date.

<u>Evaluation of separate taxa (univariate statistics)</u>

Only taxa that occurred at densities above 10 (total number of individuals in the sum of all water control treatments per sampling date) were considered. If taxonomically relevant, taxa were analyzed pooled if densities of individual taxa were too low for evaluation. Abbott's formula was used to express treatment effects relative to the control. The statistical significance of among treatment differences in

population density was determined separately for all time points using the nonparametric Mann-Whitney U test.

To reduce noise, taxa with Coefficient of Variation (CV) exceeding 1.2 (i.e. 120%) on more than three sampling moments were not used for effect evaluations. Taxa excluded from univariate evaluations were also excluded from the multivariate datasets. The author of the report stated that, as far as could be assessed, data did not indicate that these taxa that were excluded from analyses were adversely affected by the test item treatments.

Results of statistical analyses obtained from multivariate and univariate evaluations were in principle considered at an alpha level of 5%. However, for the evaluation of treatment related trends, statistical significances at an alpha level of 10% were considered in the context of graphical analysis of the results and if appropriate included in effect classification decisions.

Effects were classified according to De Jong *et al.* (2010). Different effect classes are listed below. For this study with a total post-application sampling period of two months only effect classes 1, 2, 3 and 8 are applicable. According to De Jong *et al.* (2010), recovery should to be demonstrated on two consecutive sampling moments. Due to the 4 week interval between the last two sampling moments this would result in a very conservative effect classification. Effect class 3 was therefore subdivided in class 3a (no longer statistically significant on the last two sampling dates) and class 3b (no longer statistically significant on the last sampling date).

Table B.9.5.2-01 / Table SWF-01 Effect classes according to De Jong et al. (2010)

Note: For this study (see text), effect class 3 was subdivided in class 3a (no longer statistically significant on the last two sampling dates) and class 3b (no longer statistically significant on the last sampling date).

Effect class	Description	Criteria
1	Effects could not be demonstrated (NOER)	• No (statistically significant) effects observed as a result of the treatment • Observed differences between treatment and controls show no clear causal relationship
2	Slight and transient effects	• Quantitatively restricted response of one or a few taxa and only observed on one sampling occasion
3	Pronounced short term effects; recovery within two months after first application	• Clear response of taxa, but full recovery within two months after the first application • Effects observed at two or more sampling instances
4	Pronounced effects; recovery within four months after first application	• Clear response of taxa, effects last longer than two months but full recovery within four months after the first application • Effects observed at two or more sampling instances
5	Pronounced effects; recovery within eight months after first application	• Clear response of taxa, effects last longer than four months but full recovery within eight months after the first application • Effects observed at two or more sampling instances
6	Pronounced effects; full recovery one year after first application	• Clear response of taxa, effects last longer than eight months but full recovery within one year after first application • Effects observed at two or more sampling instances
7	Pronounced effects; full recovery more than one year after first application	• Clear response of taxa, effects last longer than twelve months after the first application but full recovery found within the study period • Effects observed at two or more sampling instances
8	Pronounced effects; no recovery within the study period	• Clear response of taxa, no recovery within the duration of the study • Effects observed at two or more sampling instances

Note: For this study (see text), effect class 3 was subdivided in class 3a (no longer statistically significant on the last two sampling dates) and class 3b (no longer statistically significant on the last sampling date).

Results

Power analysis

For a rough estimation of the overall power of the univariate tests, Abbott values and P-values obtained from comparisons with the control and the toxic reference (Mann Whitney-U test) were presented in scatter plots. The minimum detection level for alpha= 0.05 was approximately 50% in the dataset including all sample types (used for final evaluations).

Arthropod species composition and abundance

Arthropod taxa with sufficiently high numbers for univariate analysis and acceptable CV (see before) were:

- *Acari*: 22 taxa, 9 of which were analysed (*Phytoseiid* female mites (mainly *Graminaseius graminis* and *Neoseiulus alpinus*); other *Gamasida* (adults and *juveniles* , including *Phytoseiidae*); *Tetranychidae*; *Tarsonemidae*; *Tydeoidea*; *Oribatida*).

- *Araneae*: *Linyphiidae (Meioneta, Erigoninae,* other *Linyphiidae*); *Lycosidae* (predominantly *Pardosa*, juveniles and adults); lynx spider *Oxyopes; Gnaphosidae*; several genera of *Thomisidae*; *Philodromidae*; *Thomisoidea*; *Theridiidae*; *Araneidae*.
- *Coleoptera*: mainly *Carabidae* (most abundant was *Harpalus*) and *Staphylinidae* (*Aleocharinae*, *Staphilininae*, *Xantholininae)* and a few plant feeding taxa (*Alticinae (Chrysomelidae)*, *Apion (Curculionidae), Latridiidae,* juvenile Coleoptera (including *Dermestidae and Carabidae)*).
- *Hymenoptera*: *Formicidae*, *Braconidae*, *Chalcidoidea* (*Aphilinidae*, *Pteromalidae*, *Trichogrammatidae, Mymaridae*, *Encyrtidae* and *Eulophidae*), *Proctotrupoidea* (*Scelionidae*, *Ceraphronidae* and other *Proctotrupoidea*), *Cynipoidea* (*Figitidae*).
- *Homoptera*: *Aphidoidae*, *Cicadellidae* (juvenile and adult stages).
- *Heteroptera*: *Lygeidae*, *Miridae*, *Tingidae*, *Cydnidae*.
- Other arthropods: *Collembola* (*Entomobryidae*, *Symphypleona*, *Isotomidae, Poduromorpha*); *Orthoptera* (*Acrididae*); *Thysanoptera*; *Lepidoptera*; *Diptera* (*Nematocera* (*Cecidomyiidae)*, *Orthorrrhapha* (*Dolichopodidae*, *Hybotidae*), *Phoridae*, *Chloropidae*, *Acalyptrata* (*Agromyzidae*), juvenile *Diptera*); *Isopoda (Oniscidae).*

This list was compared by the reviewer to Table 4 of De Jong et al. (2010), which gives an overview of taxa which should be present in off-field studies in sufficient numbers to allow univariate analyses with a sufficient power to allow for a comparison with the relevant regulatory threshold. The guidance states: “This overview is considered generally applicable to field studies in Europe. When certain taxa are lacking, this does not mean that the study is unreliable per se, but the evaluator should be triggered to ask questions about the reasons for the lack of certain taxa, and it should be argued in the study report why these taxa were not sampled, or why they are lacking. The other way around, under local conditions for some taxa a more precise level than indicated in Table 4 would be of importance. When this is known, these taxa could be included in the study.”

Only the Coleopteran taxa Coccinellidae was not present in this study. This was also not present in the other field study (see above). However, several other Coleopteran taxa are present in the current study and Coccinellidae are represented in a first tier (laboratory) study, in which they were not very sensitive. Therefore, the study is considered sufficiently representative for the off-field environment.

Altogether, a total of 79 taxa were sufficiently abundant to be subjected to population level evaluations. Multivariate analyses showed that before application, arthropod species composition and abundance was rather similar in all plots. This was deduced from the fact that all sample scores were plotted relatively close together. No clustering per block or per treatment could be detected. The test field was considered suitable for the study.

Reference product

Multivariate analysis showed that the reference treatment induced immediate and persistent (>8 weeks) adverse effects on the arthropod fauna sampled in grasslands. On all post-application sampling moments the response was statistically significant (see Figure B.9.5.2-05 Figure SWF-3). Univariate analysis showed that nearly all taxa were adversely and statistically significantly affected by the reference item treatment (see Table B.9.5.2-03 Table SWF-03). One week after the application 62.2% of the analysed taxa showed effects >50%. During the following sampling period the proportion of taxa with effects >50% decreased slowly from 59.5% after 2 weeks down to 33.8% after 8 weeks. The validity criterion for the reference treatment was clearly met (at least 50% effect on at least one sample date for at least 10% of the taxa evaluated; De Jong *et al.*, 2010). No recovery was seen for many taxa in the positive reference treatment, indicating that for the experimental period chosen, the plot size was adequate to demonstrate persistent treatment related effects. The response of the reference treatment confirmed the validity of the study.

Figure SWF-02:Proportion of Abbott values above 50% in the reference treatment. X-axis indicates sampling moments (weeks after application)

Community responses

The results for community response (pooled data from all sampling methods) are summarised in Figure B.9.5.2-08 Figure SWF-3 (first ordination axis). As the second ordination axis was not statistically significant for any of the test item rates and the percentage of variation due to treatment was low in all test item rates (12.2%), the second axis was not considered in the evaluation. The PRC graph showed differences between the highest two test item rates and the control, which were of small magnitude and short duration, and which were not statistically significant at any sampling moment. When examining community responses obtained from separate datasets, it appeared that the mite community (weed samples) and the arthropod community sampled from the soil surface (pitfall samples) did not show adverse responses to any of the BYI 02960 SL 200 treatments. It was only the

arthropod community collected with suction sampling that showed signs of transient adverse treatment related effects, but no statistically significant effects were found on any sampling moment in any of the datasets analysed.

Figure B.9.5.2-08 / Figure SWF-3: Principal Response Curve (first ordination axis)

Test- and reference items were analyzed separately but for comparison plotted in one graph. PRC analyses comprised data from weed (W)-, pitfall (P)- and suction (S) samples. Encircled data points are statistically significant (Monte-Carlo Permutation test, alpha = 0.05). The arrow indicates the application day. Test item dose rates are in g a.s./ha

Population responses

The results for arthropod abundance (univariate analysis) in the BYI 02960 SL 200 treatments and the reference treatment at pre-test and after application are summarised in the Table below.

Table B.9.5.2-03 Comparison of arthropod abundance in control and BYI 02960 SL 200 treated plots before treatment (-1) and 1, 2, 4 and 8 weeks after last treatment.

Summary of reported evaluation of population responses (minor modifications/additions by reviewer)

Three taxa (all collected with suction sampling) showed statistically significant adverse response patterns that were considered related to the test item treatment.

Aphidoidea were reduced compared to the control on three consecutive sampling moments at 21 g a.s./ha (effects 93%, 79% and 69% after 1, 2 and 4 weeks, respectively; statistically significant at α <0.05 only after 4 weeks). At the last sampling densities were similar to control densities. In all density graphs below, the Y-axis shows the number of arthropods per treatment (total of all plots per treatment), on a log-scale.

Figure B.9.5.2-09 / Figure SWF-04: Effects on Aphidoidea [Suction samples]

Juvenile *Cicadellidae* collected with suction sampling were statistically significantly reduced compared to the control 1 and 2 weeks after application at 21 g a.s./ha (effects 89% and 77%, respectively). On the last two sampling moments (4 and 8 weeks after application) densities were still reduced compared to the control (52% and 59%, respectively), but differences were no longer statistically significant (α 0.083 and 0.15, respectively). Densities in the 5.1 g a.s./ha rate were statistically significantly reduced by 70% on the sampling moment immediately after treatment. During the remainder of the sampling period densities were similar to the control in this test item treatment. These effects were not observed with juvenile *Cicadellidae* collected with pitfall sampling. *Cicadellidae* species in arable habitats on perennial host plants as in grasslands mostly have two or more generations per year. Adults at later sampling events are the grown-up juveniles of the earlier sampling events and would also occur in a lower abundance if treatment related reductions of

abundance of juveniles occur. Nevertheless, no response was observed in adult Cicadellids 2 and 6 weeks after the reduction of juveniles. There were even higher numbers of adults relative to the control not only in test plots of 21 g as/ha but also in all other plots treated with BYI 02960 SL 200. This supports the assumption that the observed effect at the test rate of 21 g a.s./ha was only of short term. The winged adults are more mobile than the larvae and could quickly stabilize the population by migration and reproduction.

Figure B.9.5.2-10 / Figure SWF-05: Effects on juvenile Cicadellidae [Suction samples]

Figure B.9.5.2-10 / Figure SWF-06: Effects on juvenile Cicadellidae [Pitfall samples]

Plant eating *Alticinae* were statistically significantly reduced in the 5.1 g and 21 g a.s./ha rate one or two weeks after application. Reductions in these two test item treatments varied between approximately 70% and 90%. Differences compared to the control were not statistically significant on the last two sampling moments. Flea beetles can also walk normally and fly, indicating a large potential for recovery. (Effect figure given in next section)

For the following taxa (all collected with suction sampling) reductions compared to the control occurred incidentally, but no consistent trend in time or relation to the dose rate was found.

Juvenile *Runcinia* (Thomisidae) were moderately but statistically significantly reduced one week after application, both in the 21 g a.s./ha rate and in the 5.1 g a.s./g ha rate (see Figure B.9.5.2-11), but pre-application densities were very low. Another taxon of the family Thomisidae, Xysticus, was present at higher numbers during application, and showed no adverse response to the test item treatment.

Addition by reviewer: in addition to the statistically significant reductions of 40% and 60% after 1 week at 5.1 and 21 g a.s./ha, respectively, a statistically significant reduction of 50% after 1 week was recorded at 1.7 g a.s./ha. For the reasons given above, this reduction at 1.7 g a.s./ha is also not likely to be a treatment related effect.

Figure B.9.5.2-11 / Figure SWF-07: Effects on juvenile Runcinia (Thomisidae) [Suction samples]

Phoridae (Diptera) were statistically significantly reduced 1 week after application (5.1 g a.s./ha) or 2 weeks after application (21 g a.s./ha). Otherwise dynamics were similar to the control. Phoridae populations collected with pitfalls were not reduced compared to the control, nor were Phoridae populations in reference treatment plots (suction and pitfall samples).

Addition by reviewer: the reduction of 61% after 1 week at 5.1 g a.s./ha is likely to be an artifact since no treatment related effect was observed after 1 week at 21 g a.s./ha.

Figure B.9.5.2-12 / Figure SWF-08: Effects on Phoridae (Diptera) [Suction samples]

Figure B.9.5.2-12 / Figure SWF-09: Effects on Phoridae (Diptera) [Pitfall samples]

The author of the report drew the following conclusions:

- BYI 02960 SL 200 applied at a rate of 21 g a.s./ha is the community NOER (No Observed Effect Rate), effect class 1.
- Only three taxa were adversely affected. At the test rate of 5.1 g a.s./ha these effects were only on single sampling occasions significant (effect class 2) and at the rate of 21 g a.s./ha they all recovered within the ecologically acceptable time frame of two months (effect class 3a and 3b). The highest rate tested in this study, BYI 02960 SL 200 applied at 21 g a.s./ha, is therefore classified as the population NOEAER (no observed ecologically adverse effect rate).

Evaluation by reviewer

The reported description and interpretation of the effects on *Aphidoidea* and juvenile *Cicadellidae* as summarised above are acceptable. The position of the author that reductions of *Runcinia* and *Phoridae* are incidental events with an uncertain relationship to treatment is supported.

Effects on *Alticinae* are displayed in Figure B.9.5.2-13 Figure SWF-10 and summarised in Table B.9.5.2-04 Table SWF-04. After 1 week, reductions were 70%, 84% and 84% at 1.7, 5.1 and 21 g a.s./ha, respectively (statistically significant at α 0.083, <0.05 and 0.059, respectively). After 2 weeks, a statistically significant reduction of 91% was recorded at 21 g a.s./ha, and no other statistically significant reductions (α <0.1) were recorded at lower treatment rates after 2 weeks and at all treatment rates after 4 and 8 weeks. However, after 4 and 8 weeks, at 21 g a.s./ha the numbers of *Alticinae* were still reduced by 89-91% relative to the control, and although these differences are no longer statistically significant, they could indicate that recovery had not occurred. However, Figure B.9.5.2-13 Figure SWF-10 shows that at 21 g a.s./ha a reduction of the population of *Alticinae* relative to the control occurred during the first 2 weeks after treatment, but, although the numbers of *Alticinae* did not return to control values during the remainder of the study, the development *rate* of the control and 21 g a.s./ha populations was very similar (as indicated by the essentiall parallel population-time graphs). The lower numbers at the end of the study would then be the result of the lower numbers at the start of the period of similar development (after 4 weeks). Therefore it may be concluded that at 21 g a.s./ha *Alticinae*, although initially adversely affected, recovered within 4 weeks. Hence, the reported evaluation of the study results and the reported conclusions are considered to be acceptable.

Figure B.9.5.2-13 / Figure SWF-10: Effects on Alticinae (Chrysomelidae) [Suction samples]

Table B.9.5.2-04 / Table SWF-04: Effects on Alticinae (reductions with α <0.1 marked in bold)

Rate g a.s./ha	Week after application

21	-11	0.47	**84**	0.06	**91**	0.05	89	0.22	91	0.15

Conclusion

BYI 02960 SL 200, single application to grassland on 20 July 2010 in South-France: community NOER 21 g a.s./ha, effect class 1; population NOEAER 5.1 g a.s./ha (effect class 2); population NOEAER 21 g a.s./ha (effect class 3b because of effects on *Aphidoidea*).

Guidelines & Limitations

Comments were incorporated in the above summary. The study is acceptable. The actual concentration of BYI 02960 in the spray solution was not confirmed by chemical analysis. However, the test material was a certified product, and since it was a Soluble Concentrate (SL), inhomogeneity in the spray tank is not likely to occur.
Several taxa showed a statistically significant increase at certain sampling points. Three taxa showed this increase at the highest dose rate at the last sampling point. These observations may result from indirect effects and therefore be relevant, but they were not explained in the report. No further information is available on this issue. Note that it would not change the outcome of the risk assessment, since this is based on a lower dose rate.

B.9.5.3 Summary and risk assessment

Procedures for risk assessment were in agreement with the recommendations in the Guidance Document on Terrestrial Ecotoxicology Under Council Directive 91/414/EEC (Working Document Sanco/10329/2002 rev 2 final, 17 October 2002, referring to ESCORT 2). The recommendations of ESCORT 3, a follow-up workshop, are taken into account for this DAR for issues where guidance is lacking.

In glasshouse crops for which Integrated Pest Management systems are used, introduced natural enemies may be exposed to flupyradifurone and, considering the results of in-field risk calculations for the field uses (see below), significantly affected This issue is not assessed in the framework of the DAR but can be taken account at Member State level.

Toxicity tests on non-target arthropods have been performed with BYI 02960 SL 200 G on the species *Typhlodromus pyri*, *Aphidius rhopalosiphi*, *Coccinella septempunctata*, *Aleochara bilineata* and *Orius laevigatus*. Furthermore, two full-fauna off-crop field studies were conducted. Table B.9.5.3-01 below summarises the results of laboratory testing with non-target arthropod species.

A: A negative value indicates a lower mortality in the treatment than in the control.
B: A negative value indicates a higher reproduction rate in the treatment than in the control.
C: A negative value indicates a higher percentage of wasps found on plants in the treatment than in the control.
D: A negative value indicates a higher nymphal hatching rate in the treatment than in the control.
n.a.: Not assessed.
sign.: statistically significant at 5%-level (only indicated for repellency).
n.sign.: not statistically significant (only indicated for repellency).

The tier 1 glass plate studies indicate that insects, as represented by *Aphidius rhopalosiphi* (LR50 < 0.5 g a.i./ha), are more sensitive to the exposure of BYI 02960 SL 200 G than mites like *Typhlodromus pyri* (LR50 17.3 g a.i./ha). This has been confirmed by extended laboratory studies for the same two species. A comparison of the extended laboratory results for *Aphidius rhopalosiphi* (LR50 2.02 g a.i./ha, ER50 >0.89 and <1.58 g a.i./ha) with the results from the additionally tested species *Coccinella septempunctata* (LR50 273.9 g a.i./ha and no effects on reproduction below the LR50) and *Aleochara bilineata* (ER50 >300 g a.i./ha) gives clear evidence, that *Aphidius rhopalosiphi* is by far the most sensitive species.

Hence, aged residue studies were conducted with *Aphidius rhopalosiphi* and - in addition - with the predatory bug *Orius laevigatus*. The results showed that *Orius laevigatus* is also susceptible to the exposure of BYI 02960 SL 200 G (effects <50% after 28 days of aging) but clearly less sensitive than

Aphidius rhopalosiphi (effects <50% after 49 days of aging). For this reason, the risk assessment of *Orius laevigatus* is considered to be covered by the risk assessment for *Aphidius rhopalosiphi*.

Data have been submitted on *Typhlodromus pyri* and *Aphidius rhopalosiphi* (i.e. two indicator species) as well as three crop-relevant species (*Coccinella septempunctata, Aleochara bilineata* and *Orius laevigatus*). From these studies a risk assessment is performed according to the recommendations of ESCORT 2.

Tier 1 risk assessment

In the 1st tier, the LR50 values of laboratory glassplate tests with the two indicator species are taken into account. The hazard quotient (HQ) is calculated as follows:

In field-HQ = max. single application rate * MAF / LR_{50}

Off-field HQ = max. single application rate * MAF * (drift factor/VDF)*correction factor / LR_{50}

- Max. single application rate = 125 g a.i./ha (lettuce), 150 g a.i./ha (hops)
- MAF (multiple application factor) = 1 (only 1 application)
- Drift factor = 19.33% (hop, 3 m distance, 1 application; ESCORT2) 2.77% (lettuce (field crops), 1m distance, 1 application; ESCORT2)
- VDF (vegetation distribution factor) = 10 (default value as recommended by the Terrestrial Guidance Document, to take into account the 3-dimensional structure of the off-field vegetation)
- Correction factor = 10 (uncertainty factor for the extrapolation from indicator species to all off-field non-target arthropods; default value for tier 1 risk assessment according to the Terrestrial Guidance Document)

The risk is considered acceptable if the calculated HQ is < 2. See the Tables below.

Table B.9.5.3-02 HQ for terrestrial non-target arthropods for the in-field scenario

Crop (field uses)	**Species**	**Appl. rate [g a.i./ha]**	**MAF**	**LR_{50} [g a.i./ha]**	**HQ**	**Trigger**
Hops	*A. rhopalosiphi*	150	1	<0.5	**>300**	2
Hops	*T. pyri*	150	1	17	**8.8**	2
Lettuce	*A. rhopalosiphi*	125	1	<0.5	**>250**	2
Lettuce	*T. pyri*	125	1	17	**7.4**	2

Conclusion: For both standard species, the in-field HQ values are above the trigger of concern, indicating a need for refinement.

Table B.9.5.3-03 HQ for terrestrial non-target arthropods for the off-field scenario

Crop	Species	Appl. rate [g a.i./ha]	MAF	Drift [%]	VDF	Corr. factor	LR_{50} [g a.i./ha]	HQ	Trigger
Hops	*A. rhopalosiphi*	150	1	19.33	10	10	<0.5	**>58**	2
Hops	*T. pyri*	150	1	19.33	10	10	17	1.7	2
Lettuce	*A. rhopalosiphi*	125	1	2.77	10	10	<0.5	**>6.9**	2
Lettuce	*T. pyri*	125	1	2.77	10	10	17	0.2	2

Conclusion: The HQ values for *Typhlodromus pyri* are below the trigger of concern for both uses. However, both HQ values for *Aphidius* are above the trigger of 2, indicating a need for refinement.

Tier 2 risk assessment

In the 2nd tier, the results of extended laboratory tests are taken into account (LR50, ER50 and/or effect percentages). These are available for four species.

The exposure is calculated as:

In-field: Application rate * MAF

In-field (high crops) Application rate * MAF * 0.5

Off-field: Application rate * MAF * (drift factor / VDF) *correction factor

- Max. single application rate = 125 g a.i./ha (lettuce), 150 g a.i./ha (hops)
- MAF (multiple application factor) = 1 (only 1 application)
- Factor 0.5 for high crops: The correction factor of 0.5 for the in-field exposure assessment in three-dimensional crops according to ESCORT2 (see footnote “a” in legend on page 19 of the ESCORT2 document) can be applied according to the notifier. However, application in hops can start from a stage in which the plants are still small, BBCH 31. The BBCH scale describes the hop plants between BBCH 31 and 38 as follows:

  Principal growth stage 3: Elongation of bines
  31 Bines have reached 10% of top wire height
  32 Bines have reached 20% of top wire height
  33 Bines have reached 30% of top wire height
  3 . Stages continuous till . . .
  38 Plants have reached the top wire

  At the beginning of the application period (BBCH 31-37), the plants are still thin and small (ca. 40cm based on a top wire size of 4m) and it is not justified to use the factor of 0.5. Furthermore, it is unclear whether the correction factor can really also be used for hops. Since no justification/validation for the use of the factor of 0.5 for other crops than orchards and vineyards, the crops mentioned in ESCORT 2, is available, the risk is calculated without correction factor.
- Drift factor = 19.33% (hop, 3 m distance, 1 application; ESCORT2; considered relevant for all grwoth stages since the same application machinery will be used throughout the season); 2.77% (lettuce (field crops), 1m distance, 1 application; ESCORT2)

- VDF (vegetation distribution factor) = 10 (default value as recommended by the Terrestrial Guidance Document, to take into account the 3-dimensional structure of the off-field vegetation; it can only be applied in the context of 2D test systems)
- Correction factor = 5 (uncertainty factor for the extrapolation from indicator species to all off-field non-target arthropods; default value for tier 2 risk assessment)

Table B.9.5.3-04 Exposure calculation for in-field assessment

Crop / no. of applications	Appl. rate [g a.i./ha]	MAF	factor to account for high crops	in-field PEC_{max}. [g/ha]
Hops BBCH 31-38 / 1	150	1	n.a.	150
Lettuce / 1	125	1	n.a.	125

Table B.9.5.3-05 Exposure calculation for off-field risk assessment

Appl. rate [g a.i./ha]	MAF	Drift [%]	Veg. distr. factor	Correction factor	off-field $PEC_{max.}$ [g/ha]	Remark
150	1	19.33	-	5	145	in case of 3-D study design
150	1	19.33	10	5	14.5	in case of 2-D study design
125	1	2.77	-	5	17.3	in case of 3-D study design
125	1	2.77	10	5	1.73	in case of 2-D study design

Tier 2 in-field risk assessment

The in-field exposure PEC values are compared to the results of the extended laboratory studies.

Table B.9.5.3-06 In-field risk assessment based on study results from extended laboratory studies

Test Species	in-field $PEC_{max.}$, [g a.i./ha]	LR_{50}/ ER_{50} [g a.i./ha]	Trigger	Refined assessment required?
Use in hops, 1 x 150 g a.i./ha				
Typhlodromus pyri	150	177 / >142	Effects are < 50%	no*
Aphidius rhopalosiphi	150	2.02 / >0.89	Effects are < 50%	**yes**
Coccinella septempunctata	150	273.9 / no effects up to 250	Effects are < 50%	no
Aleochara bilineata	150	>300	Effects are < 50%	no
Use in lettuce, 1 x 125 g a.i./ha				
Typhlodromus pyri	125	177 / >142	Effects are < 50%	no
Aphidius rhopalosiphi	125	2.02 / >0.89	Effects are < 50%	**yes**
Coccinella septempunctata	125	273.9 / no effects up to 250	Effects are < 50%	no
Aleochara bilineata	125	>300	Effects are < 50%	no

* No adverse effects on reproduction were seen up to 142 g a.s./ha. The LR50 is 177 g a.s./ha. It is likely that at 150 g a.s./ha no adverse effects on *Typhlodromus* will occur.

The higher tier in-field risk assessment for *Typhlodromus, Coccinella* and *Aleochara* indicates that no unacceptable adverse effects are to be expected in the in-field area for arthropod species with a similar sensitivity as these species. However, the in-field risk assessment for *Aphidius rhopalosiphi* indicates that initial effects in the in-field area cannot be excluded. Therefore, further refinement is needed.

Refined in-field risk assessment

The results of the tier 2 risk assessment indicate that initial effects on species with a similar sensitivity as *Aphidius rhopalosiphi* cannot be excluded. As a consequence, an aged residue study was performed to demonstrate the potential for recovery for *Aphidius rhopalosiphi*, the most sensitive tested species, and in addition for the predatory bug *Orius laevigatus*.

An extended laboratory aged residue study has been performed on *Aphidius rhopalosiphi* (Jans, 2010; KIIIA1 10.5.3/01). In this study, BYI 02960 SL 200 was applied 2 times at a rate of 250 g a.i./ha with a 10 days interval on potted maize plants. Spray residues were aged under semi-field conditions. Bioassays with freshly dried residues, residues aged for 14 days and for 28 days, respectively, resulted in a corrected morality of 100, 90 and 76.7%, respectively. After an ageing time of 42, 49 and 56 days, corrected mortalities of 29.6, 20.0 and 6.7% were recorded, respectively. Exposure to residues aged for 42 days resulted in a 89.9% reduction in reproduction relative to the control. No effects on reproduction >50% were observed after an ageing time of 49 and 56 days, respectively. Statistically significant repellency was recorded in the first, second and third bioassay (aged 0, 14 and 28 days), while in the fourth, fifth and sixth bioassay (aged 42, 49 and 56 days) no repellent effects were observed.

A second extended laboratory aged residue study has been performed on *Orius laevigatus* (Schwarz, 2010; KIIIA1 10.5.3/02). BYI 02960 SL 200 was applied 2 times at a rate of 250 g a.i./ha with an application interval of 10 days onto potted apple plants. *Orius laevigatus* showed a corrected mortality of 100 and 75.6%, when exposed to fresh residues of the test item and residues aged for 14 days, respectively. After an ageing time of 28 and 42 days, a corrected mortality of 24.5 and 9.8% was observed, respectively. No adverse effects on reproduction > 50% were observed after an ageing time of 28 and 42 days, respectively. The results indicated that *Orius laevigatus* is as well susceptible to the exposure of BYI 02960 SL 200 G (effects <50% after 28 days of ageing) but clearly less sensitive as *Aphidius rhopalosiphi* (effects <50% after 49 days of ageing).

These aged residue studies indicate that the potential for recovery is given even after 2 applications at a rate of 250 g a.i./ha within 7 weeks for the most sensitive species, *Aphidius rhopalosiphi*. For *Orius laevigatus*, residues aged for only 4 weeks already had no adverse effect on mortality and reproduction. Since the intended use pattern includes only single applications at a rate of up to

150 g a.i./ha in the field it can be concluded that the potential for recovery is given within a few weeks after the application and no unacceptable in-field risk for non-target arthropods has to be expected from the use of BYI 02960 SL 200 according to the proposed use pattern.
It is noted that the ageing in the studies was done under semi-field conditions and on plants which could potentially cause more growth dilution than other plant species, and therefore the aged residue studies do not represent all possible field conditions. Thus, a generic 'potential for recovery' period cannot be quantified. However, RMS considers that a potential for recovery within one year (the required period for in-field risk assessment according to ESCORT 2) has been shown.

Tier 2 off-field risk assessment

The off-field exposure PEC values are compared to the results of the extended laboratory studies.

Table B.9.5.3-07 Off-field risk assessment based on study results from extended laboratory studies

Test Species	**off-field $PEC_{max.}$, [g a.i./ha]**	**LR_{50}/ ER_{50} [g a.i./ha]**	**Trigger**	**Refined assessment required?**
Use in hops, 1 x 150 g a.i./ha				
Typhlodromus pyri	14.5	177 / >142	Effects are < 50%	no
Aphidius rhopalosiphi	145	2.02 / >0.89	Effects are < 50%	**yes**
Coccinella septempunctata	14.5	273.9 / no effects up to 250	Effects are < 50%	no
Aleochara bilineata	14.5	>300	Effects are < 50%	no
Use in lettuce, 1 x 125 g a.i./ha				
Typhlodromus pyri	1.73	177 / >142	Effects are < 50%	no
Aphidius rhopalosiphi	17.3	2.02 / >0.89	Effects are < 50%	**yes**
Coccinella septempunctata	1.73	273.9 / no effects up to 250	Effects are < 50%	no
Aleochara bilineata	1.73	>300	Effects are < 50%	no

The maximum PEC off-field for the use in hop (worst-case) is calculated to be 14.5 g/ha for 2D-test systems and 144.9 g/ha for 3D-test systems. For *Typhlodromus*, *Coccinella* and *Aleochara* no effects > 50% neither on mortality nor on reproduction were observed in extended laboratory studies on natural substrate at a rate of 142 (*Typhlodromus*), 250 (*Coccinella*, 2nd trial) and 300 g a.i./ha (*Aleochara*), respectively (see Table B.9.5.3-07). However, for *Aphidius*, initial effects cannot be excluded, indicating a need for further refinement.

Refined off-field risk assessment

To assess off-field effects of BYI 02960 SL 200 on naturally occurring arthropod communities under more realistic conditions, two full-fauna field studies were conducted on grassland as surrogate for off-field habitats in the Netherlands and in Southwestern France.

BYI 02960 SL 200 was applied in a dose-response design at drift rates (0.51, 1.7, 5.1 and 21 g a.i./ha) to grassland habitats with little agricultural input in the Netherlands and Southwestern France. These sites held a diverse and representative off-crop non-target arthropod community. Four replicate plots of 24 x 24 m or 22 x 22 m each were used per treatment (4 application rates, control, reference treatment = 24 plots in total). Arthropods were sampled comprehensively using three different sampling methods (pitfall, suction and weed/Berlese sampling) shortly before the application and 1, 2, 4 and 8 weeks after the application. Overall community changes relative to the control were analyzed using multivariate statistics and depicted by Principal Response Curves (PRC).
In addition, effects on individual arthropod populations were analyzed with univariate statistics for taxa that were sufficiently abundant. In both studies, the toxic reference item treatment caused clear responses both at the arthropod community level and at the population level, demonstrating that the test system was sufficiently sensitive to detect toxic effects.
Both field tests contained sufficient numbers for analysis of effects on the Hymenopteran family Braconidae, to which the most sensitive first tier species *Aphidius rhopalosiphi* belongs.

<u>Results of the trial in the Netherlands:</u>
At community level, no statistically significant effects on arthropod communities were found at any of the rates tested up to and including 21 g a.i./ha. Therefore, 21 g a.i./ha is the community NOER (No Observed Effect Rate) of BYI 02960 SL 200. In addition, 72 taxa were sufficiently abundant for a univariate statistical evaluation at population level. In the three lowest test rates, none of the taxa showed a consistent treatment-related response. Predatory mites of the family *Cunaxidae* and hymenopteran parasitoids of the family *Braconidae* showed transient adverse effects only at one sampling moment shortly after application of the highest test rate (21 g a.i./ha). Both taxa recovered within one week. In conclusion, the population NOEAER (No Observed Ecologically Adverse Effect Rate) of BYI 02960 SL 200 is 21 g a.i./ha and the population NOER (No Observed Effect Rate) is 5.1 g a.i./ha.

<u>Results of the trial in France:</u>
At community level, no statistically significant effects on arthropod communities were found at any of the rates tested up to and including 21 g a.i./ha. Therefore, 21 g a.i./ha is the community NOER (No Observed Effect Rate) of BYI 02960 SL 200.
At the population level, 79 taxa were sufficiently abundant for population level evaluations. Only three phytophagous taxa were adversely affected.
At the test rate of 5.1 g a.i./ha, significant adverse effects on the chrysomelid beetles *Alticinae* and on juvenile leafhoppers (*Cicadellidae*) occurred at a single sampling occasion. At the rate of 21 g a.i./ha,

Alticinae and *Cicadellidae* showed statistically significant reductions at two sampling moments after application, but recovered already 4 weeks after the application. Aphids (*Aphidoidea*) were reduced at several sampling moments after the application of 21 g a.i./ha; however, the reduction was only statistically significant at the penultimate sampling moment. The observed effects on *Aphidoidea* were to be expected since aphids are a target pest species for the proposed uses of BYI 02960 SL 200 in lettuce and hop. However, aphids can be expected to recover quickly from population declines due to their high asexual reproductive potential. No significant reduction in *Aphidoidea* abundance was observed at the last sampling moment two months after application of the test item. The highest rate tested in this study - BYI 02960 SL 200 applied at 21 g a.i./ha - is therefore classified as the population NOEAER (No Observed Ecologically Adverse Effect Rate) with effect class 3a; the second highest dose rate – 5.1 g a.i./ha is the NOEAER with effect class 2.

In the Terrestrial ecotoxicology guidance document and in ESCORT 2, there is no clear guidance on what endpoints should be used from field studies for risk assessment. The report from the ESCORT 3 workshop contains some relevant recommendations: (chapter 1.8.1.2, p.9) ‘ Class 3 effects may be appropiate for the off-crop in-field margin, and Class 1 and 2 are appropiate for off-field area’; (chapter 5.3, p.40) ‘ Considering field studies for off-crop risk assessment, no effect or only transient effects (e.g. de Jong et al. 2010) are considered acceptable’; and (chapter 7.1, p.49): ‘At the level of field studies, the NOER community and the NOEAER population should be used for the off-field risk assessment.’.

The drift values used to calculate the off-field exposure were determined at distances from the *crop*. In the current risk assessment, differentiation between ‘ off-crop in-field’ and ‘ off-field’ is not done. Depending on MS, crop type, farmer, etc., there may or may not be an in-field off-crop buffer zone. To ensure that the off-field is adequately protected, in this risk assessment the situation without off-crop in-field zone is assumed.

In both field studies, the community NOER is 21 g a.s./ha.
As NOEAER, three values were set:

Study in NL: 21 g a.s./ha is the population level NOEAER with effect class 2

Study in SW-FR: 5.1 g a.s./ha is the population level NOEAER with effect class 2; 21 g a.s./ha is the population level NOEAER with effect class 3a

Based on the recommendations of ESCORT 3, the community NOER and the community NOEAER values with effect class 2 are considered and the lowest of these is taken. Thus, the relevant endpoint for the risk assessment assessment would be 5.1 g a.s./ha based on the population NOEAER effect class 2 from the study in France. Because two field studies are available, the RMS does not consider an additional safety factor on this value necessary.

The relevant endpoint for the risk assessment from these studies was discussed in Pesticide Peer Review meeting 124 of December 2014. The studies had a checkerboard design, meaning that there were areas of low dose and control which could serve as source of recolonisation for the populations. The experts questioned whether there was more possibility for recolonisation in these studies than there would be in a normal agricultural off-field situation. It was therefore decided in the meeting that the NOER values could be used from these studies as these do not (less likely) account for recovery/ recolonisation.

In both field studies, the community NOER is 21 g a.s./ha.
The NOER population is:

Study in NL: 5.1 g a.s./ha
Study in SW-FR: 1.7 g a.s./ha

The lowest from these values can be used in the risk assessment, i.e. 1.7 g a.s./ha.

It was extensively discussed in the pesticide peer review meeting whether a safety factor should be applied to this value to account from uncertainties in extrapolating the results of field studies to the realistic worst case field situation. Overall, the majority of the experts agreed that no additional safety factor is required in this case given that the endpoint is a NOER and that two studies (accounting for the representativeness of the taxa) are available.

Refined potential exposure:
In the original DAR, the calculation of the off-field PEC was confusing, as reference was made to the term ‘correction factor’ while this is only appropiate for extended laboratory studies and not for field studies. This term has therefore been removed from the table below. The possible need for a safety factor, accounting for uncertainty when using field studies in the risk assessment, has already been discussed above. The vegetation distribution factor is not applicable because of the 3-D study design. The refined off-field exposure is calculated in the table below. For the use in hops, a risk is identified using the default drift value; therefore the exposure at increasing distances from the crop (and therefore decreasing drift values) is also shown.

Table B.9.5.3-08 Refined exposure calculation for off-field risk assessment

Crop / no. of applications	Appl. rate [g a.i./ha]	MAF	Distance from crop	Drift [%]	off-field PECmax. [g/ha]	Endpoint based two full-fauna field studies [g/ha]
Hops / 1	150	1	3*	19.33	29	1.7
	150	1	5	11.57	17	1.7
	150	1	10	5.77	8.7	1.7
	150	1	15	3.84	5.8	1.7
	150	1	20	1.79	2.7	1.7
	150	1	30	0.56	0.84	1.7
Lettuce / 1	125	1	1*	2.77	3.5	1.7
	125	1	5	0.57	0.71	1.7

*Default

Table B.9.5.3-08 E.13b shows that ~~the off-crop exposure is below the relevant off-field endpoint of 5.1 g a.s./ha for the use in lettuce. Therefore, the off-field risk from the use in lettuce is acceptable.~~

~~t~~he expected exposure (29 g a.s./ha) is above the relevant endpoint (1.7 ~~5.1~~ g a.s./ha) for the use in hops at the default distance from the crop. The table shows that a buffer zone of at least 30~~20~~ m would be required for the exposure value to fall below the required level. This means that acceptable use can be achieved based on the European guidance. The off-field risk from the use in hops is acceptable provided that a buffer zone of 30~~20~~ m is used.

For lettuce, the expected exposure (3.5 g a.s./ha) is above the relevant endpoint (1.7 ~~5.1~~ g a.s./ha) at the default distance from the crop. The table shows that a buffer zone of at least 5 m would be required for the exposure value to fall below the required level.

Note that other options for risk mitigation may be possible (e.g. drift reducing nozzles or the presence of off-crop in-field buffer zones which would give the option to use a higher endpoint). Risk mitigation measures are set at Member State level.

B.9.6 Effects on earthworms (IIA 8.9, IIIA 10.6)

B.9.6.1 Acute toxicity to earthworms (IIA 8.9.1)

STUDY IIA, 8.9.1/01

Characteristics

reference	:	Leicher T. (2010a)	purity	:	96.2%
type of study	:	Acute toxicity	species	:	*Eisenia foetida*
year of execution	:	2009-2010	exposure duration	:	14 days
GLP statement	:	Yes	nominal conc.	:	5.6, 10, 18, 32, 56, 100, 178, 562 and 1000 mg/kg soil d.w.
Guideline	:	OECD 207 (1984)	dosing method	:	Soil was treated with mixture of test substance and quartz sand
test substance	:	BYI 02960 (tech.), batch 2009-000239	LC50	:	185.6 mg a.s./kg soil d.w. (10% organic matter)

Methods

In an acute toxicity study, earthworms (*Eisenia fetida*, adults, mean weight 350 mg) were exposed to BYI 02960 technical for 14 days in artificial soil (OECD 207 substrate, with 10% organic matter). The test was conducted in 1.5 L glass jars covered with glass lids, containing 595 g d.w. artificial soil.

Two trials 1 and 2 were performed. Treatment rates in trial 1 were 5.6, 10, 18, 32, 56 and 100 mg/kg soil d.w.. Trial 2 was performed at higher treatment rates since in trial 1 only 3% mortality was observed at the highest treatment rate after 14 days. Treatment rates in trial 2 were 178, 562 and 1000 mg/kg soil d.w..

Each treatment and the controls were tested in 4 replicates of 10 worms each. Test soils were prepared by treating the artificial soil with a mixture of the test substance and quartz sand. The control was treated with quartz sand only. Jars were maintained at 20±2°C under continuous light (400-800 lux). Soil moisture was in the range 53-58% of WMHC at the start and the end of the test. The soil pH was in the range 5.6-5.7 at the start and end of the test. A reference product (2-chloroacetamide) was tested in a separate test about 1 year earlier and gave an acceptable result (14-day LC50 13.2 mg/kg soil d.w. in artificial soil with 10% organic matter).

Results

Test results are summarised in the table below. The results of the control group satisfied the guideline requirements (OECD 207, 1984): ≤10% mortality. The 14-day LC50 (Probit analysis) was 192.9 mg/kg soil d.w. (95% CI 143.3-276.9 mg/kg soil d.w.), equivalent to 185.6 mg a.s./kg soil d.w..

Table B.9.6.1-01 Acute toxicity of BYI 02960 technical to *Eisenia fetida*

Nominal concentration (mg/kg soil d.w.)	Mortality at 14 days (%)	Mean weight change survivors over 14 days (%)
control	0	-3
5.6	0	-12*
10	0	-13*
18	0	-17*
32	0	-20*
56	0	-23*
100	3	-25*

178	23	-25*
316	95	-38*
562	100	-
1000	100	-

* statistically significant difference from control at 5% level.

Conclusion

14-day LC50 185.6 mg a.s./kg soil d.w. (soil with 10% organic matter).

Guidelines and limitations

The study was performed according to OECD 207 (1984) and is acceptable. Test rates were expressed as mg t.i./kg soil d.w. (mg test item/kg soil d.w.). Test rates were not corrected for active ingredient content of the technical active substance (96.2%). The correction of the LC50 from 192.9 mg/kg soil d.w. to 185.6 mg a.s./kg soil d.w. was performed by the reviewer.

STUDY IIIA, 10.6.2/01

Characteristics

reference	:	Leicher T. (2010e)	a.s. content	:	17.1% w/w (201.0 g/L) BYI 02960
type of study	:	Acute toxicity	species	:	*Eisenia foetida*
year of execution	:	2010	exposure duration	:	14 days
GLP statement	:	Yes	nominal conc.	:	100, 178, 316, 562, 1000 and 1780 mg test item/kg soil d.w.
Guideline	:	OECD 207 (1984), OPPTS 850.6200	dosing method	:	Soil was treated with solution of test substance in water
test substance	:	BYI 02960 SL 200 G (200 g/L SL formulation), batch 2009-001067	LC50	:	121 mg a.s./kg soil d.w. (5% organic matter)

Methods

In an acute toxicity study, earthworms (*Eisenia fetida*, adults, mean weight 310 mg) were exposed to BYI 02960 SL 200 G (200 g/L SL formulation, 17.1% w/w (201.0 g/L) BYI 02960) for 14 days in artificial soil (OECD 207 substrate, with 5% peat). The test was conducted in 1.5 L glass jars covered with glass lids, containing 595 g d.w. artificial soil. Treatment rates were 100, 178, 316, 562, 1000 and 1780 mg test item/kg soil d.w.. Each treatment and the controls were tested in 4 replicates of 10 worms each. Test soils were prepared by treating the artificial soil with a solution of the test substance in water. The control was treated with water only. Jars were maintained at 20±2°C under continuous light (400-800 lux). Soil moisture was in the range 57-58% of WMHC at the start and the end of the test. The soil pH was in the range 6.1-6.2 at the start and the end of the test. A reference product (2-chloroacetamide) was tested in a separate test about 7 months earlier and gave an acceptable result (14-day LC50 26.1 mg test item/kg soil d.w. in artificial soil with presumably 10% organic matter).

Results

Test results are summarised in the table below. The results of the control group satisfied the guideline requirements (OECD 207, 1984): ≤10% mortality. The 14-day LC50 (Probit analysis) was 709 mg test item/kg soil d.w. (95% CI 245-2187 mg test item/kg soil d.w.), equivalent to 121 mg a.s./kg soil d.w..

Table B.9.6.1-03 Acute toxicity of BYI 02960 SL 200 G to *Eisenia fetida*

Nominal concentration (mg test item/kg soil d.w.)	Mortality at 14 days (%)	Mean weight change survivors over 14 days (%)
control	0	+4
100	0	-16*
178	3	-22*
316	0	-28*
562	28	-36*
1000	78	-48*
1780	100	-

* statistically significant difference from control at 5% level.

Conclusion

14-day LC50 121 mg a.s./kg soil d.w. (soil with 5% organic matter).

Guidelines and limitations

The study was performed according to OECD 207 (1984) and is acceptable.

STUDY IIA, 8.9.1/02

Characteristics

reference	:	Leicher T. (2010b)	purity	:	95.8%
type of study	:	Acute toxicity	species	:	*Eisenia foetida*
year of execution	:	2010	exposure duration	:	14 days
GLP statement	:	Yes	nominal conc.	:	31.3, 62.5, 125, 250, 500 and 1000 mg/kg soil d.w.
Guideline	:	OECD 207 (1984)	dosing method	:	Soil was treated with mixture of test substance and quartz sand
test substance	:	BYI 02960-difluoroacetic acid, batch number BCOO 5984-1	LC50	:	>958 mg pure metabolite/kg soil d.w. (10% organic matter)

Methods

In an acute toxicity study, earthworms (*Eisenia fetida*, adults, mean weight 320 mg) were exposed to difluoroacetic acid (metabolite of BYI 02960) for 14 days in artificial soil (OECD 207 substrate, with 10% organic matter). The test was conducted in 1.5 L glass jars covered with glass lids, containing 595 g d.w. artificial soil. Treatment rates were 31.3, 62.5, 125, 250, 500 and 1000 mg/kg soil d.w.. Each treatment and the controls were tested in 4 replicates of 10 worms each. Test soils were prepared by treating the artificial soil with a mixture of the test substance and quartz sand. The control was treated with quartz sand only. Jars were maintained at 20±2°C under continuous light (400-800 lux). Soil moisture was in the range 51-54% of WMHC at the start and the end of the test. The soil pH was 6.2-6.3 at the start of the test and 6.0 at the end. A reference product (2-chloroacetamide) was tested in a separate test about 1 year and 4 months earlier and gave an acceptable result (14-day LC50 13.2 mg/kg soil d.w. in artificial soil with 10% organic matter).

Results

Test results are summarised in the table below. The results of the control group satisfied the guideline requirements (OECD 207, 1984): ≤10% mortality. The 14-day LC50 was >1000 mg/kg soil d.w. equivalent to >958 mg pure metabolite/kg soil d.w..

Table B.9.6.1-02 Acute toxicity of difluoroacetic acid to *Eisenia fetida*

Nominal concentration (mg/kg soil d.w.)	Mortality at 14 days (%)	Mean weight change survivors over 14 days (%)
control	0	+6
31.3	0	+5
62.5	0	-2*
125	0	-4*
250	2.5	-6*
500	0	-8*
1000	0	-11*

* statistically significant difference from control at 5% level.

Conclusion

14-day LC50 >958 mg pure metabolite/kg soil d.w. (soil with 10% organic matter).

Guidelines and limitations

The study was performed according to OECD 207 (1984) and is acceptable. Test rates were expressed as mg t.i./kg soil d.w. (mg test item/kg soil d.w.). Test rates were not corrected for active ingredient content of the test item (95.8%). The correction of the LC50 from >1000 mg/kg soil d.w. to >958 mg pure metabolite/kg soil d.w. was performed by the reviewer.

STUDY IIA, 8.9.1/03

Characteristics

reference	:	Wetton P.M. (1999)	purity	:	99.7%
type of study	:	Acute toxicity	species	:	*Eisenia foetida*
year of execution	:	1999	exposure duration	:	14 days
GLP statement	:	Yes	nominal conc.	:	1000 mg/kg soil d.w.
Guideline	:	OECD 207 (1984)	dosing method	:	Test substance was added directly to soil.
test substance	:	IC-0 = 6-chloronicotinic acid (6-CNA); batch MF-4267	LC50	:	>1000 mg/kg soil d.w. (10% organic matter)

Methods

In an acute toxicity limit study, earthworms (*Eisenia fetida*, adults, mean weight about 400 mg) were exposed to IC-0 (6-chloronicotinic acid, metabolite of BYI 02960) for 14 days in artificial soil (OECD 207 substrate, with 10% organic matter). The test was conducted in 1 L glass jars covered with perforated plastic film, containing 500 g d.w. artificial soil. The test substance (3.5 g) was added directly to 3.5 kg of the test substrate. The treatment rate was 1000 mg/kg soil d.w.. The control was untreated. The treatment and the control were tested in 6 replicates of 10 worms each. Jars were maintained at 21°C under continuous light (598-700 lux). Soil moisture was 24-25% of soil d.w. at the start and 20-21% and the end of the test. This level is considered to be adequate (MWHC of OECD 207 substrate with 10% peat is about 50-55%). The soil pH was 6.1-6.3 at the start of the test and 6.2-6.4 at the end. A reference product (2-chloroacetamide) was tested once every 6 months in a separate test and gave an acceptable result (14-day LC50 23 mg/kg soil d.w. in artificial soil with 10% organic matter).

Results

Mortality in the control and the IC-0 treatment was 5% and 2%, respectively, after 14 days. Earthworm weights were unaffected by the treatment with IC-0. The 14-day LC50 was >1000 mg/kg soil d.w..

Conclusion

14-day LC50 >1000 mg/kg soil d.w. (soil with 10% organic matter).

Guidelines and limitations

The study was performed according to OECD 207 (1984) and is acceptable.

B.9.6.2 Sublethal effects on earthworms (IIA 8.9.2)

STUDY IIA, 8.9.2/01 & IIIA, 10.6.3/01

Characteristics

reference	:	Leicher T. (2010c)	species	:	*Eisenia fetida andrei*
type of study	:	Sublethal toxicity study	exposure duration	:	8 weeks
year of execution	:	2010	nominal conc.	:	8.9, 15.8, 28.1, 50 and 89 mg test item/kg soil d.w.
GLP statement	:	Yes	dosing method	:	Soil was treated with a dispersion of test substance in water
guideline	:	OECD 222 & ISO 11268-2	acceptability	:	Acceptable
test substance	:	BYI 02960 SL 200 G (200 g/L SL formulation), batch 2009-001253	NOEC	:	8.9 mg test item/kg soil d.w. (1.5 mg a.s./kg soil d.w.) (10% organic matter)
a.s. content	:	17.0 % w/w (199.8 g/L) BYI 02960			

Methods

In a chronic toxicity study, earthworms (*Eisenia fetida andrei*, clitellate adults, 250-450 mg at the start) were exposed to BYI 02960 SL 200 G (200 g/L SL formulation, 17.0 % w/w (199.8 g/L) BYI 02960) for 4 weeks in artificial soil (OECD 222 substrate with 10% peat). After this period, the adults were removed and cocoons remained in the test vessels for 4 more weeks. The test was conducted in 16.5 x 12 x 6 cm plastic boxes covered with perforated transparent lids containing 500 g of soil (based on d.w.). To prepare the highest test concentration, the test substance was dispersed in deionised water and mixed with the test soil. Lower concentrations were prepared by serial dilution. Nominal soil concentrations of 8.9, 15.8, 28.1, 50 and 89 mg test item/kg soil d.w. were tested in 4 replicates of 10 worms each, with an untreated control tested in 8 replicates. Vessels were maintained at 18-22°C under a 16 hours light (400-800 lux) and 8 hours dark photoperiod. Cattle manure (5 g per container per event) was added as food on day 1 after application and weekly thereafter for the first 4 weeks. Soil moisture was maintained at 49-52% of MWHC during the test. The soil pH was 6.13 at the start of the test and 6.4-6.5 at the end. After four weeks, survival and growth rate of adults were determined, and after eight weeks the number of offspring. In a separate study conducted about 1 year earlier, a positive control (carbendazim) was tested.

Results

The positive control gave the expected response (NOEC 1.25 mg a.s./kg soil d.w., effects on reproduction from 2.5 mg a.s./kg soil d.w.). Test results are summarised in the Table below. The results of the control group satisfied the guideline requirements (OECD 222, 2004): ≤10% adult mortality, ≥30 offspring per replicate, CV for reproduction ≤30%.

None of the differences in weight change between the BYI 02960 SL 200 G treatments and the control were statistically significant at the 5% level. Based on statistically significant reductions of the number of offspring at 15.8 mg test item/kg soil.d.w. and above, the NOEC is 8.9 mg test item/kg soil d.w., equivalent to 1.5 mg a.s./kg soil d.w..

Table B.9.6.2-01 Chronic toxicity of BYI 02960 SL 200 G to *Eisenia fetida*

Concentration (mg test item/kg soil d.w.)	Adult mortality after 28 days (%)	Mean weight change over 28 days (%)	No. of juveniles per replicate
Control	0	+44.6	220.0 (CV 10.3%)
8.9	0	+48.1	205.3
15.8	2.5	+52.0	190.0*
28.1	5	+52.9	188.8*
50	0	+43.8	162.8*
89	0	+45.4	130.0*

* statistically significant difference from control at 5% level.

Conclusion

NOEC 8.9 mg test item/kg soil d.w., equivalent to 1.5 mg a.s./kg soil d.w. (soil with 10% organic matter).

Guidelines and limitations

The study was performed according to OECD 222 (2004) and is acceptable.

STUDY IIA, 8.9.2/02

Characteristics

GLP statement	:	Yes	dosing method	:	Test item was added to soil mixed with quartz sand
Guideline	:	OECD 222 & ISO 11268-2	acceptability	:	Acceptable
test substance	:	BYI 02960-difluoroacetic acid; batch code BCS-AA56716-01-01, batch number BCOO 5984-1-1	NOEC	:	59 mg pure metabolite/kg soil d.w. (10% organic matter)
Purity	:	95.8%			

Methods

In a chronic toxicity study, earthworms (*Eisenia fetida andrei*, clitellate adults, 250-450 mg at the start) were exposed to BYI 02960-difluoroacetic acid (metabolite of BYI 02960) for 4 weeks in artificial soil (OECD 222 substrate with 10% peat). After this period, the adults were removed and cocoons

remained in the test vessels for 4 more weeks. The test was conducted in 16.5 x 12 x 6 cm plastic boxes covered with perforated transparent lids containing 500 g of soil (based on d.w.). To prepare the test substrates, the test substance was mixed with quartz sand and the mixture was added to the artificial soil substrate. Nominal soil concentrations of 11, 20, 35, 62 and 110 mg test item/kg soil d.w. were tested in 4 replicates of 10 worms each, with a control treated with quartz sand only tested in 8 replicates. Vessels were maintained at 18-22°C under a 16 hours light (400-800 lux) and 8 hours dark photoperiod. Cattle manure (5 g per container per event) was added as food on day 1 after application and weekly thereafter for the first 4 weeks. Soil moisture was maintained at 55-56% of MWHC during the test. The soil pH was 6.01 at the start of the test and 6.4-6.5 at the end. After four weeks, survival and growth rate of adults were determined, and after eight weeks the number of offspring. In a separate study conducted about 1 year earlier, a positive control (carbendazim) was tested.

Results

The positive control gave the expected response (NOEC 1.25 mg a.s./kg soil d.w., effects on reproduction from 2.5 mg a.s./kg soil d.w.). Test results are summarised in the Table below. The results of the control group satisfied the guideline requirements (OECD 222, 2004): ≤10% adult mortality, ≥30 offspring per replicate, CV for reproduction ≤30%.

None of the differences in weight change between the difluoroacetic acid treatments and the control were statistically significant at the 5% level. Based on a statistically significant reduction of the number of offspring at 110 mg test item/kg soil.d.w., the NOEC is 62 mg test item/kg soil d.w., equivalent to 59 mg pure metabolite/kg soil d.w..

Table B.9.6.2-02 Chronic toxicity of BYI 02960-difluoroacetic acid to *Eisenia fetida*

Concentration (mg test item/kg soil d.w.)	Adult mortality after 28 days (%)	Mean weight change over 28 days (%)	No. of juveniles per replicate
Control	0	+66.6	264.8 (CV 11.6%)
11	0	+61.8	259.8
20	0	+63.3	373.5
35	0	+60.4	282.3
62	0	+61.5	230.3
110	0	+60.2	190.0*

* statistically significant difference from control at 5% level.

Conclusion

NOEC 59 mg pure metabolite/kg soil d.w. (soil with 10% organic matter).

Guidelines and limitations

The study was performed according to OECD 222 (2004) and is acceptable. Test rates were not corrected for active ingredient content of the test substance (95.8%). The correction of the NOEC from 62 mg test item/kg soil d.w. to 59 mg pure metabolite/kg soil d.w. based on test item purity of 95.8% was performed by the reviewer.

STUDY IIA, 8.9.2/03

Characteristics

reference	:	Leicher T. (2011)	species	:	*Eisenia fetida andrei*
type of study	:	Sublethal toxicity study	exposure duration	:	8 weeks
year of execution	:	2010-2011	nominal conc.	:	9.5, 16.8, 30.0, 53.4, 95.0 and 100 mg test item/kg soil d.w.
GLP statement	:	Yes	dosing method	:	Test item was added to soil mixed with quartz sand
guideline	:	OECD 222 & ISO 11268-2	acceptability	:	Acceptable
test substance	:	6-chloronicotinic acid (6-CNA = IC-0); batch AE F161089 00 1B99 0001	NOEC	:	95 mg/kg soil d.w. (soil with 5% organic matter)
purity	:	98.8%			

Methods

In a chronic toxicity study, earthworms (*Eisenia fetida andrei*, clitellate adults, 250-450 mg at the start) were exposed to 6-chloronicotinic acid (6-CNA = IC-0, metabolite of BYI 02960) for 4 weeks in artificial soil (OECD 222 substrate with 5% peat). After this period, the adults were removed and cocoons remained in the test vessels for 4 more weeks.

Two trials 1 and 2 were performed. The treatment rate in trial 1 was 100 mg test item/kg soil d.w. (limit test). Trial 2 was performed at lower treatment rates since in trial 1 a statistically significant reduction of body weight gain and rate of reproduction was observed. Treatment rates in trial 2 were 9.5, 16.8, 30.0, 53.4 and 95.0 mg test item/kg soil d.w..

The test was conducted in 16.5 x 12 x 6 cm plastic boxes covered with perforated transparent lids containing 500 g of soil (based on d.w.). To prepare the test substrates, the test substance was mixed with quartz sand and the mixture was added to the artificial soil substrate. In the limit test (trial 1), the nominal soil concentration of 100 mg test item/kg soil d.w. was tested in 8 replicates of 10 worms, with a control treated with quartz sand also tested in 8 replicates. In the dose-response test (trial 2), the nominal soil concentrations of 9.5, 16.8, 30.0, 53.4 and 95.0 mg test item/kg soil d.w. were tested in 4 replicates of 10 worms each, with a control treated with quartz sand tested in 8 replicates. Vessels were maintained at 18-22°C under a 16 hours light (400-800 lux) and 8 hours dark photoperiod. Cattle manure (5 g per container per event) was added as food on day 1 after application and weekly thereafter for the first 4 weeks. Soil moisture was maintained at 56-65% of MWHC during the test. The soil pH in trial 1 was 6.3 at the start of the test and 6.7-7.0 at the end. The soil pH in trial 2 was 5.8 at the start of the test and 6.6 at the end. After four weeks, survival and growth rate of adults were determined, and after eight weeks the number of offspring. In a separate study conducted about 1 year earlier, a positive control (carbendazim) was tested.

Results

The positive control gave the expected response (NOEC 1.25 mg a.s./kg soil d.w., effects on reproduction from 2.5 mg a.s./kg soil d.w.). Test results are summarised in the Table below. The results of the control group satisfied the guideline requirements in both tests (OECD 222, 2004): ≤10% adult mortality, ≥30 offspring per replicate, CV for reproduction ≤30%.

In the dose-response test, weight change and reproduction rate of the 6-chloronicotinic acid treatment was statistically significantly lower (5% level) than in the control. In the dose-response test, none of

the differences in weight change and reproduction rate between the 6-chloronicotinic acid treatments and the control were statistically significant at the 5% level. Based on a statistically significant reduction of the number of offspring at 100 mg test item/kg soil.d.w., the NOEC is 95 mg test item/kg soil d.w (no correction required considering the high test item purity).

Table B.9.6.2-03 Chronic toxicity of 6-chloronicotinic acid to *Eisenia fetida*

Concentration (mg test item/kg soil d.w.)	Adult mortality after 28 days (%)	Mean weight change over 28 days (%)	No. of juveniles per replicate
Limit test			
Control	0	+72.8	211.9 (CV 14.2%)
100	0	+56.7*	107.4*
Dose-response test			
Control	0	+59.2	215.1(CV 13.6%)
9.5	0	+55.8	208.0
16.8	0	+56.0	199.0
30.0	0	+49.9	222.3
53.4	0	+49.5	180.0
95.0	0	+53.3	186.0

* statistically significant difference from control at 5% level.

Conclusion

NOEC 95 mg/kg soil d.w..(soil with 5% organic matter).

Guidelines and limitations

The study was performed according to OECD 222 (2004) and is acceptable. An explanation for the somewhat conflicting results of the limit test and the findings at 95 mg/kg in the dose-response test was not provided by the author of the report. Further questions are considered to be redundant considering the order of magnitude of the NOEC.

B.9.6.4 Earthworms field studies (IIA 10.6.4)

IIIA 10.6.4/01

Characteristics

reference	:	Menke U. (2012)	test organism	:	Field populations of earthworms
type of study	:	Earthworm field study	exposure duration	:	11 months
year of execution	:	2010-2011	nominal dose	:	One application at 300, 600 or 1500 g a.s./ha
GLP statement	:	Yes	dosing method	:	Sprayed on grassland
guideline	:	BBA VI, 2-3 (1994), ISO 11268-3 Part 3 (1999)	acceptability	:	~~Acceptable~~ **Not acceptable**
test substance	:	BYI 02960 SL 200 G (200 g/L SL formulation), batch 2010-001067	conclusion	:	~~No lasting effect after a spring application on grassland at 1500 g a.s./ha (soil with 1.98% OC)~~
a.s. content	:	17.1% w/w (201 g/L) BYI 02960			

Methods

The effect of BYI 02960 SL 200 G (200 g/L SL formulation, 17.1% w/w (201 g/L) BYI 02960) on earthworm populations was investigated in Germany near the Höfchen Experimental Station of the

Bayer CropScience AG under field conditions after one spray application on grassland at dose levels of 300, 600 and 1500 g a.s./ha on 25 May 2010, with untreated control and reference product (Carbendazim SC 500, 10000 g a.s./ha).

Trial lay out and treatment

Prior to trial lay out, the test site had been cultivated as grassland for many years. In the three years preceding the test onset, the field had not been treated with pesticides. During the study period, agricultural practice was conducted: plots were mown 12 days before application and the mulch was removed 5 days before application. Mulching was performed 6 times during the remaining study period (21 June, 20 August, 17 September, 8 October and 26 October 2010 and 31 March 2011), the mulch was left on the surface. A pre-sampling of earthworms was performed 8 days before application from 16 spots across the study site and revealed sufficiently high and diverse earthworm populations (4.8/m^2 *L. terrestris* (anecic), 72/m^2 *L. rubellis* + *L. castaneus* (epigeic), 46/m^2 *A. caliginosa* (endogeic), 5.0/m^2 *A. chlorotica* (endogeic), 128/m^2 total earthworms)

The soil characteristics are shown in Table B.9.6.3-01 (determined from soil sampled on April 04, 2011). To establish the test site, 10 x 10 m plots were established. The BYI 02960 SL 200 G treatment, the untreated control and the reference product were each assigned to four replicate plots. Applications were made in 400 L water/ha on 25 May 2010, according to normal agricultural practice (no further information).

Table B.9.6.3-01 Properties of study soil

(A) DIN 4220

Earthworm sampling

From each plot earthworms were sampled (4 areas of 0.25 m^2 within the inner 6 x 6 m area of each plot) by formalin extraction. Samplings were conducted on 22-23 June 2010 (4 weeks after treatment), 27-28 October and 05 November 2010 (5 months after treatment) and on 5-6 April 2011 (11 months after treatment). Adult earthworms and juveniles were identified to species level and their numbers and weights recorded. Before each sampling (including the pre-test sampling) the efficiency of the formalin extraction method was checked and the sampling efficiency was 69%, 61%, 73% and 74% at pre-test and after 4 weeks, 5 months and 11 months, respectively (hence above the criterion of at least 60% specified in ISO 11268-3). In addition to the above, surface monitoring for direct mortality effects on earthworms was performed the first few days after application.

Irrigation

No irrigation was applied as 15.3 mm of rain fell on the day after application, with a total of 59.4 mm during the first 9 days after application.

Environmental conditions

Climatic data were recorded at the nearby experimental farm Laacher Hof of the Bayer CropScience AG.

Chemical soil analysis

Soil cores (10 cm deep, 50 mm diameter, 20 cores per plot) were collected within 24 hours after treatment and analysed for BYI 02960 using method 01074/M0001 (extraction followed by LC-MS/MS, LOQ 5 µg/kg, concurrent validation by fortified samples at 5, 300, 600 and 1500 µg/kg (n=1 at each level), recoveries 68% (5 µg/kg) and 93-98% (300-1500 µg/kg). Method 01074 was validated in soil according to SANCO/3029/99 rev.4 of 11/07/00, but method 01074/M0001 differed from method 01074 in that it used an internal standard whereas method 01074 employed matrix matched standards. Although method 01074/M0001 is therefore not considered to be fully validated, further information is not considered necessary, since (1) sampling of soil is not mandatory according to ISO 11268-3 and according to De Jong *et al.* (2006) (De Jong *et al.*, Guidance for Summarising Earthworm Field Studies, RIVM Report 601506006/2006); (2) three concurrent recoveries were determined for

fortification levels representative for those of the study samples, and found to be excellent (93-98%), indicating that the use of an internal standard leads to accurate results in this range.

Soil samples were stored frozen for about 10 months prior to analysis. Storage stability in soil was not demonstrated. Further information is not considered necessary, since (see results) the measured concentrations in soil (means per treatment rate in range 118-136% of expected concentrations) were within the acceptable range of 50-150% specified in Kula *et al.* (2006) (Kula C., Heimbach F., Riepert F. and Rombke J. 2006. technical recommendations for the update of the ISO earthworm field test guideline (ISO 11268-3). Journal of Soil and Sediments 6, 182-186).

Statistical analysis

Total and species abundance and biomass data were statistically evaluated by the Wilcoxon, Mann and Whitney U-test (α=0.05, two-sided). Shannon-Weaver diversity indices were calculated for each sampling point for adult, juvenile and sum of adult and juvenile earthworms separately.

Results

Environmental conditions

The environmental conditions are shown in the Table below.

*) mean of 1966 – 2006
**) mean of 1966 – 2005

Soil analysis

Samples taken from the control plots contained low residues of BYI 02960 (5.28 µg/kg; at least 45 times lower than the residues in any of the plots of the lowest BYI 02960 treatment). After application,

the mean measured concentration (mean of 4 plots) of BYI 02960 at nominal treatment rates of 300, 600 and 1500 g a.s./ha, respectively, was 271, 472 and 1234 µg/kg soil, corresponding to 136%, 118% and 123% of the expected PECsoil of 200, 400 and 1000 µg/kg soil, calculated for a soil depth of 10 cm and an assumed soil density of 1.5 kg/dm^3. The measured soil concentrations were within the range of 50-150% indicated by Kula *et al* (2006) as the acceptable range.

Earthworm surface searches

Some earthworms (at the most 2 on any day) could be detected on the soil surface of treated and control plots. The data did not indicate any difference between treated and control plots.

Earthworm abundance and biomass

The results for earthworm abundance and biomass are summarised in the tables below. At the pre-test count, mean earthworms abundance was 128 individuals per square meter, which is sufficient to provide valid data (the guideline requires a minimum of 60). Mean earthworm density in the control plots was 68, 402 and 264 individuals per square meter at 4 weeks, 5 months and 11 months after treatment. The low density in the control after 4 weeks can be explained by the dry and warm weather conditions at that time in combination with the sampling type (under these weather conditions especially endogeic species may enter diapause and they would then be missed with formalin extraction, which requires earthworm activity; hand sorting would have probably resulted in higher numbers). It may hamper statistical evaluation, but is still higher than the required number of 60, and since the main endpoints from this study are derived from samplings at later stages and high densities were achieved at those stages, it does not invalidate the study.

The reference product carbendazim gave the expected response, with a statistically significant reduction of total earthworm abundance and biomass after 4 weeks (effect >50%) and 5 months (effect >50% on biomass), confirming the validity of the study.

The collected adult earthworms with sufficient abundance belonged to 2 endogeic taxa, 2 epigeic taxa and 1 anecic taxon. During the pre-test sampling, the most abundant endogeic species was *Aporrectodea caliginosa* (36% of total earthworms) followed by *Allolobophora chlorotica* (4% of total earthworms); the most abundant anecic earthworm species was *Lumbricus terrestris* (4% of total earthworms). The most abundant epigeic species was *Lumbricus rubellis*/*Lumbricus castaneus* (57% of total earthworms). Because of similar external taxonomic characters of the immature (juvenile) epigeic worms, a classification to the individual species level was sometimes not possible. Therefore *L. rubellus* and *L. castaneus* were combined and are presented as "total epigeic earthworms" or "juvenile epigeic earthworms " in Table B.9.6.3-02 to B.9.6.3-04. The class "epigeic species" may also

contain a small percentage of juvenile *L. terrestris*, which, based on their size, could not be classified as *L. terrestris*.

At 4 weeks after treatment, at 300 g a.s./ha no statistically significant or biologically relevant adverse effects on abundance and biomass were recorded. At 600 g a.s./ha, statistically significant reductions of biomass of total earthwoms (-33%) and of total adult earthworms (-41%) were recorded. At 1500 g a.s./ha, statistically significant reductions were recorded of abundance of total earthwoms (-33%) and total adult earthworm (-44%), and of abundance (-45%) and biomass (-47%) of adult epigeic earthworms, the latter associated with statistically significant reduced biomass (-46%) of adult *L. rubellis*. Non-statistically significant reductions of abundance of total *L. terrrestris* at 600 and 1500 g a.s./ha (-60% and -57%, respectively) and associated reductions of total anecic earthworms (-60% and -57%, respectively) are considered to be of doubtful biological relevance considering the very low number of adults and juvenile *L. terrrestris* in the control (2.5/m^2 and 7.6/m^2, respectively).

At 5 months after treatment, at 300 g a.s./ha no statistically significant or biologically relevant adverse effects on abundance and biomass were recorded. At 5 months after treatment, statistically significant biologically relevant and treatment related effects were reductions of abundance of adult *L. caliginosa* (-38%, 1500 g a.s./ha) and associated adult endogeic earthworms (-37%, 1500 g a.s./ha) and biomass of adult *L. caliginosa* (-32% and -45% at 600 and 1500 g a.s./ha, respectively), and associated reductions of biomass of adult and total endogeic earthworms (-45% and -42%, respectively, 1500 g a.s./ha) and of total *A. caliginosa* (-30% and -42%, 600 and 1500 g a.s./ha, respectively).

At 600 and 1500 g a.s./ha, statistically significant reductions of abundance of juvenile anecic earthwoms were recorded (-55% and -50%, respectively), corresponding with identical statistically significant reductions of juvenile *L. terrestris*. The abundance and biomass of total *L. terrestris*, and the associated abundance and biomass of total anecic earthworms, were statistically significantly reduced at 600 g a.s./ha (-57%, -61%, -57% and -61%, respectively). The biomass of adult *L. terrestris* and the associated biomass of adult anecic earthworms was statisticaly significantly reduced at 600 g a.s./ha (-63% and -63%, respectively). These findings are considered to be of doubtful biological relevance in view of (1) the lack of a dose-response relationship in the range 300-1500 g a.s./ha for the effects on abundance of juvenile anecic earthworms and juvenile *L. terrestris*; (2) the inverse dose-response relationship for the effects on abundance and biomass of total *L. terrestris* and total anecic earthworms; (3) the inverse dose-response relationship for the effects on biomass of adult *L. terrestris* and adult anecic earthworms; (4) the relatively low numbers of juvenile *L. terrestris* in the control (10.4 individuals/m^2).

At 11 months after treatment, at 300 g a.s./ha no statistically significant or biologically relevant adverse effects on abundance and biomass were recorded. At 600 and 1500 g a.s./ha, no statistically significant and/or biologically relevant reductions of abundance and biomass of any taxon were determined, although statistically significant reductions of abundance and biomass of juvenile anecic earthworms (range -50% to 65%) were recorded, corresponding with identical statistically significant reductions of juvenile *L. terrestris*. These findings however are considered to be of doubtful biological relevance in view of the low numbers of juvenile *L. terrestris* in the control (8.4 individuals/m^2) and the very low numbers of adult *L. terrestris* in the control (3.2 individuals/m^2). Several other effects of >50% relative to the control were recorded at this sampling, but these effects were considered to be due to biological variation and unrelated to the treatment as they were not statistically significant, mostly based on very low numbers of individuals in the control, and in most cases represented increases relative to the control, hence not adverse effects. It is concluded that under the conditions tested, the use of BYI 02960 SL 200 G will not present a sustained unacceptable effect on biomass and abundance of earthworm communities.

Tables B.9.6.3-03 to -05 show the results. Bold values represent statistically significant reductions; these cells are marked yellow for the test item treatments.

Table B.9.6.3-03 Earthworm abundance in control and reductions of earthworm abundance (mean of 4 0.25 m^2 plots per treatment) in field soil **4 weeks after treatment** with BYI 02960 SL 200 G (200 g/L BYI 02960) at 300, 600 and 1500 g a.s./ha or with Carbendazim SC 500 (10000 g a.s./ha). page 478

Not statistically analysed because of too low abundance

- Not analysed because of too low abundance

* Statistically significant difference compared to control at the 5% level

Shannon-Weaver diversity index (Hs)

The results are summarised in the Table below. The species diversity in all BYI 02960 SL 200 G treatments tended to be reduced relative to the control at 4 weeks after application, although a dose-relationship was not apparent. At 5 and 11 months after application, diversity indices in treated plots were comparable to those in control plots.

Table B.9.6.4-06 Shannon-Weaver diversity index (Hs)

Conclusion

BYI 02960 SL 200 G did not induce lasting adverse effects on the earthworm community following a spring application in grassland up to 1500 g a.s./ha (1.98% organic carbon), corresponding to a measured concentration of 1234 µg/kg soil.

Remarks

The study was performed according to ISO 11268-3 and is acceptable. The abundance of endogeic and epigeic earthworms during the study was high, but that of anecic earthworms (*L. terrestris*) was in general too low in the control plots to allow reliable conclusions for this category. The RMS considered

that the species distribution, including the low numbers of anecic earthworms (*L. terrestris*) is considered to be a feature of the test plots, and does not invalidate the study. However, in the pesticide peer review meeting 124 of December 2014, it was noted that the effects of the test substance on the number and the biomass of juveniles of *Lumbricus terrestris* looked significant and constant over the test period of 11 months showing a concentration dependent trend without recovery. It was also noted that if the effects on *L. terrestris* are disregarded as proposed by the RMS, the effects on anecic (burrowing) earthworms cannot be estimated since *L. terrestris* was the only representative of this group.

In the peer review meeting it was furthermore noted that the abundance of other species besides *L. terrestris* was quite low. The results of sampling collected after 4 weeks were questioned due to too hot and dry conditions. However, it was noted that the abundance in general was sufficient at the beginning of the test. After 4 weeks, the abundance in the control (although individual groups had a low number which does not match with the recommendations of the guideline) was higher than the treated plots.

Low residues of the a.s. were found in the control plots. Contamination may have occurred via spray drift. Since the residues are at least 45 times lower than those in the treatment plots, RMS considers that ~~the results of the study can still be used~~ this does not invalidate the study.

The residue concentration in soil was measured over 10 cm. Usually, for spray applications it is assumed that the initial residues are distributed over a 5 cm layer, therefore it the approach used may be worst case (expressed over 5 cm the endpoint could be doubled). It is however unknown whether the residues in the 10 cm soil cores were evenly distributed or indeed only present in the top 5 cm layer. ~~Therefore, the risk assessment should be based on the endpoint mentioned under study conclusion.~~

Overall, the experts in the pesticide peer review meeting considered the study as not reliable for risk assessment.

B.9.6.4 Summary and risk assessment

Procedures for risk assessment were in agreement with the recommendations in the Guidance Document on Terrestrial Ecotoxicology under Council Directive 91/414/EEC (Working Document Sanco/10329/2002 rev 2 final, 17 October 2002). Two soil metabolites require further consideration according to the fate section: DFA and 6-CNA.

B.9.6.4.1 Acute risk to earthworms

The table below presents a summary of the acute toxicity studies on earthworms.

Table B.9.6.4.1-01 Acute effects of BYI 02960 and relevant metabolites on earthworms

Test species	Test design	Ecotoxicological endpoint			Reference
BYI 02960					
Eisenia fetida	acute, 14 d (10% peat in test soil)	LC_{50}	185.6	mg a.i./kg dws	Leicher (2010) KIIA 8.9.1/01
BYI 02960 SL 200 G					
Eisenia fetida	acute, 14 d (5% peat in test soil)	LC_{50}	121	mg a.i./kg dws	Leicher (2010) KIIIA 10.6.2/01
DFA					
Eisenia fetida	acute, 14 d (10% peat in test soil)	LC_{50}	> 958	mg p.m./kg dws	Leicher (2007) KIIA 8.9.1/02
6-CAN					
Eisenia fetida	acute, 14 d (10% peat in test soil)	LC_{50}	> 1000	mg p.m./kg dws	Wetton (1999) KIIA 8.9.1/03

dws = dry weight soil
a.i. = active ingredient; p.m. = pure metabolite

For lipophilic substances (log POW > 2) the Terrestrial Guidance Document recommends to apply an additional assessment factor of 2 for the ecotoxicological endpoints (LC50, NOEC), if the study was conducted in artificial soil with a high content of organic matter (i.e. 10 % peat), to consider the possible sorption of these compounds to the organic matter. However, BYI 02960 and its metabolites have a log POW < 2 and no additional assessment factor has to be applied.

The toxicity values are compared with the PECsoil values from section B.8.3 (maximum concentration after multiple year use: $PEC_{initial}$ after one application + $PEC_{accumulation}$). The $PEC_{initial}$ is expressed over 5 cm. For hops, the $PEC_{accumulation}$ is expressed over 5 cm (perennial crop without tillage). For lettuce, the $PEC_{accumulation}$ is expressed over 20 cm (annual crop with tillage). The acute TER values are presented in Table B.9.6.3.1-02.

Table B.9.6.4.1-02 TER_{acute} calculations for earthworms

Compound test design	End point	[mg/kg soil]	$PEC_{max,accu}$ [mg/kg soil]	TER_{acute}	Trigger	Refined risk assessment?
Hops						
BYI 02960	LC_{50}	185.6	0.160	2.3E+3	10	
BYI 02960 SL 200	LC_{50}	121	0.160	7.6E+2	10	No
DFA	LC_{50}	>958	0.009	> 11E+4	10	
6-CNA	LC_{50}	>1000	0.007	> 14E+4	10	
Lettuce biennial						
BYI 02960	LC50	185.6	0.141	1.3E+3	10	
BYI 02960 SL 200	LC50	121	0.141	8.6E+2	10	No
DFA	LC50	>958	0.014	> 68E+3	10	
6-CNA	LC50	>1000	0.012	≥ 83E+3	10	
Lettuce annual						
BYI 02960	LC50	185.6	0.063	2.9E+3	10	
BYI 02960 SL 200	LC50	121	0.063	1.9E+3	10	No
DFA	LC50	>958	0.006	> 16E+4	10	
6-CNA	LC50	>1000	0.005	> 20E+4	10	

The TER values in Table B.9.6.4.1-02 are far above the Annex VI 91/414 EEC trigger of 10. Hence the acute risk to earthworms is considered to be acceptable.

B.9.6.4.2 Chronic risk to earthworms

The table below presents a summary of the chronic toxicity studies on earthworms.

Table B.9.6.4.1-03 Chronic effects of BYI 02960 and relevant metabolites on earthworms

Test species	Test design	Ecotoxicological endpoint	Reference
BYI 02960 SL 200 G			
Eisenia fetida	reproduction, 56 d (10% peat in test soil)	NOEC 1.5 mg a.i./kg dws	Leicher (2010) KIIIA1 10.6.3/01
DFA			
Eisenia fetida	reproduction, 56 d (10% peat in test soil) mixing	NOEC 59 mg p.m./kg dws	Leicher (2010) KIIA 8.9.2/02
6-CNA			
Eisenia fetida	reproduction, 56 d (10% peat in test soil) mixing	NOEC 95 mg p.m./kg dws	Leicher (2011) KIIA 8.9.2/03

dws = dry weight soil
a.i. = active ingredient; p.m. = pure metabolite

The toxicity values are compared with the PECsoil values from section B.8.3 (maximum concentration after multiple year use: $PEC_{initial}$ after one application + $PEC_{accumulation}$). The $PEC_{initial}$ is expressed over

5 cm. For hops, the $PEC_{accumulation}$ is expressed over 5 cm (perennial crop without tillage). For lettuce, the $PEC_{accumulation}$ is expressed over 20 cm (annual crop with tillage). The long-term TER values are presented in Table B.9.6.3.1-02.

Table B.9.6.4.1-04 $TER_{long-term}$ calculations for earthworms

Compound test design	End point	[mg/kg soil]	$PEC_{max,accu}$ [mg/kg soil]	TER_{lt}	Trigger	Refined risk assessment?
Hops						
BYI 02960 SL 200	NOEC	1.5	0.160	9.4	5	No
DFA	NOEC	59	0.009	6.6E+3	5	
6-CNA	NOEC	95	0.007	14E+3	5	
Lettuce biennial						
BYI 02960 SL 200	NOEC	1.5	0.141	11	5	No
DFA	NOEC	59	0.014	4.2E+3	5	
6-CNA	NOEC	95	0.012	7.9E+3	5	
Lettuce annual						
BYI 02960 SL 200	NOEC	1.5	0.063	24	5	No
DFA	NOEC	59	0.006	9.8E+3	5	
6-CNA	NOEC	95	0.005	19E+3	5	

The TER values in Table B.9.6.4.1-04 are above the Annex VI 91/414 EEC trigger of 5. Hence the chronic risk to earthworms is considered to be acceptable.

B.9.6.4.3 Field studies with earthworms

The above risk assessments indicate that no acute or long-term risk is to be expected for earthworms from the proposed uses of BYI 02960 in hops and lettuce.

A field study with earthworms was performed nevertheless. In this one year earthworm field study, BYI 02960 SL 200 G was sprayed on grassland at 300, 600 and 1500 g a.i./ha corresponding to measured concentrations of 271, 472 and 1234 µg/kg soil (mean of four plots). Reduction of abundance (-33%) and biomass (-38%) at 1500 g a.i./ha and biomass at 600 g a.i./ha (-36%) after 1 month were seen, but there was full recovery of earthworm population after 11 months. The measured concentrations in soil at the start of the study (up to 1.234 mg/kg soil measured over 10 cm, see remarks to the field study above) cover the expected concentrations at the proposed uses (up to 0.160 mg/kg soil). ~~The study confirms the expected acceptable risk to earthworms.~~ However, the study was considered invalid by the experts of the pesticide peer review meeting of December 2014. Therefore,

this study cannot be used for the risk assessment. This has no influence on the outcome of the risk assessment, since this was already acceptable based on laboratory studies.

B.9.7 Effects on soil non-target macro-organisms (IIIA 10.6.6)

B.9.7.1 Toxicity studies with soil non-target macro-organisms other than earthworms

a.s. content	:	17.0% w/w (199.8 g/L) BYI 02960			

Methods

In a 28-day reproduction study, springtails (*Folsomia candida*) were exposed to BYI 02960 SL 200 G (200 g/L SL formulation, 17.0% w/w (199.8 g/L) BYI 02960) for 28 days in artificial soil prepared according to OECD 207, but with 5% peat. The test was performed in two runs, since in the first run statistically significant effects on reproduction were noted at the lowest test concentration. Test concentrations were 8.8, 13.2, 19.9, 29.8 and 44.6 mg test item/kg soil d.w. in run 1, and 5.88, 7.06 and 8.47 mg test item/kg soil d.w. in run 2. The test substance was dissolved in water and mixed into the soil. The control was treated with water only. A positive control (Betosip, 157 g/L phenmedipham, 50-200 mg product/kg soil d.w.) was tested less than one year earlier. The test was conducted in 100 mL glass jars (5 for each treatment and the control) covered with glass lids containing 30 g of moist soil and 10 springtails (10-12 days old) at test initiation. Containers were maintained at 18-22°C under a 16 h light regime (400-800 lux). Soil moisture was maintained at 41-49% of MWHC. The pH was 5.6-6.1 at the start and 5.3-5.7 at 28 days, when adult survival and the number of juveniles were assessed.

Results

The positive control gave the expected response (NOEC <50 mg product/kg soil d.w.; test conducted in soil with 5% peat, therefore effects on reproduction were higher than recommended by ISO 11267: effects at 100-200 mg product/kg soil d.w.). Other results are summarised in the table below. The results of the control group satisfied the guideline requirements: ≤20% adult mortality, ≥100 instar juveniles per test vessel, CV for reproduction ≤30%. The most sensitive test endpoint, reproduction, as measured by the number of offspring, was significantly reduced at 8.8 mg test item/kg and above. The NOEC is 8.47 mg test item/kg soil d.w., equivalent to 1.44 mg a.s./kg soil d.w..

Table B.9.7-01 Effects of BYI 02960 SL 200 G on *Folsomia candida*

Test item Test object Exposure		BYI 02960 SL 200 G *Folsomia candida* Artificial Soil		
Nominal concentration mg/kg artificial soil dry weight test item	a.s.	Adult mortality (%)	Mean number of juveniles±SD	Reproduction (% of control)
First test run				
Control		2	1340 ± 60	-
8.8	1.5	2	1111 ± 120	83*
13.2	2.3	6	934 ± 144	70*
19.9	3.4	12	680 ± 130	51*
29.8	5.1	14	427 ± 169	32*
44.6	7.6	44	196 ± 61	15*
Second test run				
Control		4	1202 ± 101	-
5.88	1.00	14	1289 ± 104	107
7.06	1.20	14	1308 ± 97	109
8.47	1.44	12	1166 ± 121	97
$NOEC_{reproduction}$ (mg test item/kg soil dry weight)				8.47
$LOEC_{reproduction}$ (mg test item/kg soil dry weight)				8.8

The calculations were performed with unrounded values
* = statistically significant (William's T-test one-sided-smaller, α = 0.05)

Conclusion

NOEC 8.47 mg test item/kg soil d.w. equivalent to 1.44 mg a.s./kg soil d.w. (soil with 5% organic matter).

Guidelines and limitations

The study was conducted in agreement with ISO 11267 (1999) and is acceptable.

STUDY IIA, 8.14/02

Characteristics

reference	:	Frommholz U. (2010a)	species	:	*Folsomia candida*
type of study	:	Laboratory reproduction toxicity study	exposure duration	:	28 days

GLP statement	:	Yes	dosing method	:	Test item was added to soil mixed with quartz sand
guideline	:	OECD 232	acceptability	:	Acceptable
test substance	:	BYI 02960-difluoroacetic acid; batch BCOO 5984-1-1	NOEC	:	95.8 mg pure metabolite/kg soil d.w. (soil with 5% organic matter)
a.s. content	:	95.8%			

Methods

In a 28-day reproduction study, springtails (*Folsomia candida*) were exposed to BYI 02960-difluoroacetic acid (metabolite of BYI 02960) for 28 days in artificial soil prepared according to OECD 207, but with 5% peat. The test concentration was 100 mg test item/kg soil d.w.. To prepare the test

substrate, the test substance was mixed with quartz sand and the mixture was added to the artificial soil substrate. The control was treated with quartz sand only. A positive control (boric acid, 44-225 mg/kg soil d.w.) was tested less than one year earlier. The test was conducted in 100 mL glass jars (8 for each treatment and the control) covered with glass lids containing 30 g of moist soil and 10 springtails (10-12 days old) at test initiation. Containers were maintained at 18-22°C under a 16 h light regime (400-800 lux). Soil moisture was maintained at 42-49% of MWHC. The pH was 5.6 at the start and 5.6-5.7 at 28 days, when adult survival and the number of juveniles were assessed.

Results

The positive control gave the expected response (EC50 for reproduction 96 mg/kg soil d.w.). Other results are summarised in the table below. The results of the control group satisfied the guideline requirements: ≤20% adult mortality, ≥100 instar juveniles per test vessel, CV for reproduction ≤30%. The NOEC is 100 mg test item/kg soil d.w., equivalent to 95.8 mg pure metabolite/kg soil d.w..

Table B.9.7-02 Effects of BYI 02960-difluoroacetic acid on *Folsomia candida*

Test item Test object Exposure	Metabolite BYI 02960-difluoroacetic acid *Folsomia candida* Artificial soil		
mg test item/kg soil dry weight nominal concentration	Adult mortality (%)	Mean number of juveniles±SD	Reproduction (% of control)
Control	2.5	1337 ± 175	-
100	1.3	1268 ± 146	95 n.s.
$NOEC_{reproduction}$ (mg test item/kg soil dry weight) $LOEC_{reproduction}$ (mg test item/kg soil dry weight)			≥100 >100

The calculations were performed with un-rounded values
n.s. = statistically not significant (Student-t test one-sided-smaller, α = 0.05)

Conclusion

NOEC 95.8 mg pure metabolite/kg soil d.w. (soil with 5% organic matter).

Guidelines and limitations

The study was performed according to OECD 232 and is acceptable. Test rates were not corrected for active ingredient content of the test substance (95.8%). The correction of the NOEC from 100 mg test item/kg soil d.w. to 95.8 mg pure metabolite/kg soil d.w. based on test item purity of 95.8% was performed by the reviewer.

STUDY IIA, 8.14/03

Characteristics

reference	:	Frommholz U. (2011b)	species	:	*Folsomia candida*
type of study	:	Laboratory reproduction toxicity study	exposure duration	:	28 days

year of execution	:	2011	nom. conc.	:	Run 1: 100 mg test item/kg soil d.w.; Run 2: 10, 17, 30, 52 and 90 mg test item/kg soil d.w.
GLP statement	:	Yes	dosing method	:	Test item was added to soil mixed with quartz sand
guideline	:	OECD 232	acceptability	:	Acceptable
test substance	:	6-chloronicotinic acid (6-CNA = IC-0); batch M12653	NOEC	:	90 mg/kg soil d.w. (soil with 5% organic matter)
a.s. content	:	98.8%			

Methods

In a 28-day reproduction study, springtails (*Folsomia candida*) were exposed to 6-chloronicotinic acid (6-CNA = IC-0, metabolite of BYI 02960) for 28 days in artificial soil prepared according to OECD 207, but with 5% peat. The test was performed in two runs, since in the first run a statistically significant effect on reproduction were noted at the only tested concentration. Test concentrations were 100 mg test item/kg soil d.w. in run 1, and 10, 17, 30, 52 and 90 mg test item/kg soil d.w. in run 2. To prepare the test substrate, the test substance was mixed with quartz sand and the mixture was added to the artificial soil substrate. The control was treated with quartz sand only. A positive control (boric acid, 44-225 mg/kg soil d.w.) was tested less than one year earlier. The test was conducted in 100 mL glass jars (8 for each treatment and the control in run 1, 8 for the control and 4 for the treatments in run 2), covered with glass lids, containing 30 g of moist soil and 10 springtails (10-12 days old) at test initiation. Containers were maintained at 18-22°C under a 16 h light regime (400-800 lux). Soil moisture was maintained at 43-48% of MWHC. The pH was 5.6-5.9 at the start and 5.5-5.8 at 28 days, when adult survival and the number of juveniles were assessed.

Results

The positive control gave the expected response (EC50 for reproduction 91 mg/kg soil d.w.). Other results are summarised in the table below. The results of the control group satisfied the guideline requirements: ≤20% adult mortality, ≥100 instar juveniles per test vessel, CV for reproduction ≤30%.
The NOEC is 90 mg test item/kg soil d.w. (no correction required considering the high test item purity).

Conclusion

NOEC 90 mg/kg soil d.w. (soil with 5% organic matter).

Guidelines and limitations

The study was performed according to OECD 232 and is acceptable.

STUDY IIA, 8.14/04

Characteristics

reference	:	Kratz M.-A. (2009a)	species	:	*Hypoaspis aculeifer*
type of study	:	Laboratory reproduction toxicity study	exposure duration	:	14 days
year of execution	:	2009	nom. conc.	:	100, 178, 316, 562 and 1000 mg test item/kg soil d.w.
GLP statement	:	Yes	dosing method	:	Test substance was dissolved in water and mixed into the soil
guideline	:	OECD 226	acceptability	:	Acceptable
test substance	:	BYI 02960 SL 200 G (200 g/L SL formulation), batch 2009-001253	NOEC	:	1000 mg test item/kg soil d.w. (170 mg a.s./kg soil d.w.), soil with 5% organic matter
a.s. content	:	17.0% w/w (199.8 g/L) BYI 02960			

Methods

In a 14-day reproduction study, soil mites (*Hypoaspis aculeifer*) were exposed to BYI 02960 SL 200 G (200 g/L SL formulation, 17.0% w/w (199.8 g/L) BYI 02960) at 100, 178, 316, 562 and 1000 mg test item/kg dry soil for 14 days in artificial soil prepared according to OECD 226 (5% organic matter). The test substance was dissolved in water and mixed into the soil. The control was treated with water only. A positive control (dimethoate, 0.98-8.92 mg/kg soil d.w.) was tested less than one year earlier. The

test was conducted in glass containers (four for each treatment and eight for the control), covered with glass lids and containing 20 g d.w. test substrate and 10 mites (adult, fertilised, 28-day old females) at test initiation. Containers were maintained at 18-22°C under a 16 h light regime (400-800 lux). Soil moisture was maintained at 47-50% of MWHC. The pH was 5.6-5.8 at the start and 5.5-5.8 at 14 days, when adult survival and the number of juveniles were assessed using an extraction method.

Results

The positive control gave the expected response (EC50 for reproduction 5.45 mg a.s./kg dw). Other results are summarised in the table below. The results of the control group satisfied the guideline requirements (OECD 226, 2008): ≤20% adult mortality, ≥50 juveniles per test vessel, CV for reproduction ≤30%. None of the differences between the test item treatments and the control were statistically significant at the 5% level. The NOEC is 1000 mg test item/kg soil d.w., equivalent to 170 mg a.s./kg soil d.w..

Conclusion

NOEC 1000 mg test item/kg soil d.w., equivalent to 170 mg a.s./kg soil d.w. (soil with 5% organic matter).

Guidelines and limitations

The study was conducted in agreement with OECD 226 (2008) and is acceptable.

STUDY IIA, 8.14/05

Characteristics

reference	:	Kratz M.-A. (2010)	species	:	*Hypoaspis aculeifer*
type of study	:	Laboratory reproduction toxicity study	exposure duration	:	14 days
year of execution	:	2010	nom. conc.	:	Run 1: 63, 125, 250, 500 and 1000 mg test item/kg soil d.w.; Run 2: 1000 mg test item/kg soil d.w.

GLP statement	:	Yes	dosing method	:	Test item was added to soil mixed with quartz sand
guideline	:	OECD 226	acceptability	:	Acceptable
test substance	:	BYI 02960-difluoroacetic acid; batch BCOO 5984-1-1	NOEC	:	958 mg pure metabolite/kg soil d.w. (soil with 5% organic matter)
a.s. content	:	95.8%			

Methods

In a 14-day reproduction study, soil mites (*Hypoaspis aculeifer*) were exposed to BYI 02960-difluoroacetic acid (metabolite of BYI 02960) for 14 days in artificial soil prepared according to OECD 226 (5% organic matter). The test was performed in two runs, since in the first run in at least one replicate of each treatment and the control a few juveniles were inadvertantly introduced at the start of the test. Test concentrations were 63, 125, 250, 500 and 1000 mg test item/kg soil d.w. in run 1, and 1000 mg test item/kg soil d.w. in run 2. To prepare the test substrate, the test substance was mixed with quartz sand and the mixture was added to the artificial soil substrate. The control was treated with quartz sand only. A positive control (dimethoate, 1.0-10 mg/kg soil d.w.) was tested less than one year earlier. The test was conducted in glass containers (four for each treatment and eight for the control in run 1; eight for the treatment and the control in run 2), covered with glass lids and containing 20 g d.w. test substrate and 10 mites (adult, fertilised, 35-day old (run 1) or 28-day old (run 2) females) at test initiation. Containers were maintained at 18-22°C under a 16 h light regime (400-800 lux). Soil moisture was maintained at 43-53% of MWHC. The pH was 5.6-6.3 (run 1) or 5.5 (run 2) at the start and 5.4-6.1 (run 1) or 4.9-5.4 (run 2) at 14 days, when adult survival and the number of juveniles were assessed using an extraction method.

Results

The positive control gave the expected response (EC50 for reproduction 5.7 mg a.s./kg dw). Other results are summarised in the table below. The results of the control group satisfied the guideline requirements (OECD 226, 2008): ≤20% adult mortality, ≥50 juveniles per test vessel, CV for reproduction ≤30%. Negative % mortality values were obtained in the first test run because together with the adult females inadvertently juveniles were transferred to the test vessels at the start of the test and became adult during the test run. The numbers of juveniles of individual replicates obtained during the 1st test run suggested that inadvertently inserted juveniles didn't reproduce during the test run. Therefore all counted juveniles were considered as reproduction of the initially inserted adults by the author of the report. However, the results of the first run may be ignored, since the results of the properly performed second run clearly demonstrated that the NOEC is 1000 mg test item/kg soil d.w., equivalent to 958 mg pure metabolite/kg soil d.w..

Table B.9.7-05 Effects of BYI 02960-difluoroacetic acid on *Hypoaspis aculeifer*

1st test run

Test item Test object Exposure	BYI 2960-DFA (BCS-AA56716) *Hypoaspis aculeifer* Artificial Soil		
	% mortality (Adults)	Mean number of juveniles per test vessel ± standard dev.	Reproduction (% of control)
Control	5.0	369.9 ± 44.3	---
63	-7.5	393.0 ± 50.1	106.3

Conclusion

NOEC 100 mg/kg soil d.w. (soil with 5% organic matter).

Guidelines and limitations

The study was conducted in agreement with OECD 226 (2008) and is acceptable.

B.9.7.2 Summary and risk assessment for soil non-target macro-organisms other than earthworms

The Guidance Document on Terrestrial Ecotoxicology Under Council Directive 91/414/EEC (Sanco 10329/2002, rev 2 final) states that a 'higher degree of scrutiny' for the soil organism risk assessment is required if the field DT90 values in soil are >100 days. The field DT90 values for BYI 02960 and the laboratory DT90 (no field studies available) for metabolites DFA and 6-CNA are >100 days. Therefore, studies with *Folsomia candida* and *Hypoaspis aculeifer* were performed with the formulated product and the two metabolites. See Table B.9.7-07.

Table B.9.7-07 Effects on other soil non-target macro-organisms

Test species	Test design	Ecotoxicological endpoint			Reference
BYI 02960 SL 200 G					
Folsomia candida	chronic, 28 d (5% peat in test soil)	NOEC	1.44	mg a.s./kg dws	Frommholz (2009) KIIA 8.14/01, KIIIA1 10.6.6/01
Hypoaspis aculeifer	chronic, 14 d (5% peat in test soil)	NOEC	≥ 170	mg a.s./kg dws	Kratz (2010) KIIA 8.14/04, KIIIA1 10.6.6/02
DFA					
Folsomia candida	chronic, 28 d (5% peat in test soil)	NOEC	≥ 95.8	mg p.m./kg dws	Frommholz (2010) KIIA 8.14/02
Hypoaspis aculeifer	chronic, 14 d (5% peat in test soil)	NOEC	≥ 958	mg p.m./kg dws	Kratz (2010) KIIA 8.14/05
6-CNA					
Folsomia candida	chronic, 28 d (5% peat in test soil)	NOEC	90	mg p.m./kg dws	Frommholz (2010) KIIA 8.14/03
Hypoaspis aculeifer	chronic, 14 d (5% peat in test soil)	NOEC	≥ 100	mg p.m./kg dws	Kratz, A. (2011) KIIA 8.14/06

dws = dry weight soil
p.m. = pure metabolite

The toxicity values are compared with the PECsoil values from section B.8.3 (maximum concentration after multiple year use: $PEC_{initial}$ after one application + $PEC_{accumulation}$). The $PEC_{initial}$ is expressed over 5 cm. For hops, the $PEC_{accumulation}$ is expressed over 5 cm (perennial crop without tillage). For lettuce, the $PEC_{accumulation}$ is expressed over 20 cm (annual crop with tillage). The long-term TER values are presented in Table B.9.6.3.1-08 and -09.

Table B.9.6.4.1-08 $TER_{long\text{-}term}$ calculations for *Folsomia candida*

guideline	:	OECD 56 (2006)	dosing method	:	plateau concentration incorporated followed by annual concentration oversprayed
test substance	:	BYI 02960 SL 200 G, Batch no: 2010-001067, density 1.175 g/mL	acceptability	:	Acceptable
a.s. content	:	201 g/L analysed, 17.1% w/w	NOEC	:	237 µg as/kg d.w. (soil with 1.9% organic matter)

Description

Litterbag study was performed at the Bayer Experimental farm Höfchen, Burscheid, Germany.

Site characteristics

Silty loam, pH 6.47, 1.09% organic carbon (equivalent to 1.9 o.m.), microbial C 477 mg/kg dry soil. Cation exchange capacity 14.5 meq/100 g. Since 2007 the following plant protection products were applied: Basagran DP (bentazone, herbicide), Stomp SC (pendimethalin, herbicide) and Tristar (acetamiprid, insecticide)

Application, concentrations, replicates

Study was conducted in twelve plots, six treatment plots and six untreated plots with a size of 9 m x 9 m = 81 m^2 each.

On June 14, 2010, the test item was applied at a rate of 150 g as/ha (corresponding to 750 mL test item/ha) in 300 L water/ha, and incorporated into the upper 10 cm soil layer. Assuming a soil bulk density of 1500 L/kg, this procedure leads to a corresponding concentration of 0.1 mg as/kg soil in a depth of 0-10 cm, which represents the calculated plateau concentration . Details about calculation of the plateau concentration are not presented in the litterbag report, plateau concentration was provided by the sponsor. On June 16, untreated summer wheat seed sort ‘Chamsin’ was sown at a seeding rate of 230 kg seed/ha. Then, litterbags were buried after sowing. Litterbags (12x22 cm, mesh size 8mm) were filled with 4 g dry wheat straw. In the centre of each plot, 40 litterbags were buried horizontally at a depth of 5 cm with a distance of about 15 cm between each other in each direction. On the same day the second application was performed, at the annual rate of 300 g as/ha (corresponding to 1490 mL test item/ha) in 300 L water/ha.

Sampling of spray solutions.

Samples of spray solutions were taken before application of the plateau concentration. Spray solution samples were not analysed, however, because no need was present, given the clear results of the soil samples.

Soil sampling and analysis.

On July 14, 2007, directly after incorporation of the first application and on June 21, 2010, (5 days after burying of the litterbags and application of annual rate), samples were taken from the soil (each sample consisted of two soil cores per plot). Soil samples of 10 cm depth were randomly taken outside the litterbag area and avoiding a zone of about 1 m from the edge of each plot. Samples were stored frozen until analysis. Soil samples were analysed according to Analytical method 01074/M001. This method is suitable for determination of the active substance (BYI 02960) and the metabolites 6-chloronicotinic acid and difluoroacetic acid using HPLC-MS/MS. Only the active substance will be analysed. LOQ of the method is 5.0 µg/kg for the active substance. Soil samples were kept in the freezer until analysis in March-May 2011.

Removal and processing of litterbags

On three occasions (29, 92 and 217 days after burying (July 15, September 16 and January 19), eight litterbags per plot and sampling time were selected in a randomised procedure. Of the 40 litterbags per plot, eight litterbags were used per sampling time. Litterbags were air-dried to interrupt microbial degradation. Contents were ground and sieved in order to remove any soil for the degraded straw. The remaining mixture of straw and residual mineral soil was dried at a temperature of 35º C for a minimum of 2 hours, before the loss by ignition was determined (30 minutes at 600 ºC).

Calculations and statistical evaluation

Weight difference of the straw between the start of the experiment and the actual sampling time was calculated and used to calculate the degree of degradation. Because separation of litter and soil organic matter is not complete, in accordance with the guidance a correction was applied to correct for possible contribution of soil organic matter to the ash-free dry weight.

Cochran's test was conducted to test for homogeneity of variances and Kolmogorov-Smirnov Test was conducted to test for normal distribution. A Student-t test (two sided, α = 0.05) was performed to determine statistically significant differences between control and treatment. If conditions for homogeneity and/or and normality were not met, data transformation was applied and otherwise the non-parametric Mann-Whitney Pairwise U-test was chosen.

Results

Weather conditions

As no precipitation occurred at June 16 and 17, after the application of the annual rate, plots were irrigated with 6 mm water on June 18. Sum of precipitation at June 20 of 9.5 mm was considered enough for exposure of the soil organisms to the product. Monthly precipitation during test period was 12.2, 88.0, 203.0, 109.0, 60.6, 129.0, 67.5 and 113.9 mm in the months June to January, respectively.

Measured soil concentrations.

Mean concentrations of flupyradifurone at June 14 (directly after application and incorporation of the plateau concentration) were 89 µg as/kg dry soil in the treated plots, which is 89% of the nominal amount of 100 µg as/kg dry soil (= calculated plateau concentration) (see Table 9.9.1-1 .). At June 21 (5 days after application of the annual rate), mean measured concentration in the treated plots was 237 µg as/kg dry soil , which is 79% of the theoretical amount 5 days after application of the annual

rate and including the plateau rate. These data were corrected for analytical recovery rate of 104%. All calculations assume a soil depth of 10 cm and a soil density of 1.5 g/mL. Concentrations in the samples of the control plots were all <LOQ.

Table 9.9.1-1 . Nominal and analytically verified amount of flupyradifurone, means from 6 plots (copied from report Table 4)

	Nominal application rate	
	[µg a.s./kg dry soil]	[g a.s./ha]
Plateau concentration	100	150
Cumulative annual application	200	300
∑	300	450
	Analysed concentrations	
	[µg a.s./kg dry soil]	% of nominal amount
Plateau concentration [soil samples taken after incorporation]	89	89
Plateau concentration + Cumulative annual application [soil samples taken six days after application]	237	79

Degradation of straw

The degree of degradation was determined by calculating the weight difference of the straw between the start of the experiment and the actual sampling time.

Table 9.9.1-2 .Ddegradation of 4 g straw (means of 6 plots. Table copied from report summary.

Means of 4 plots	Control	BYI 02960 SL 200 G	% of Control[1)]	% Effect[2)]
0 – 29 d *			92	8
g straw degraded	0.93	0.86		
% straw degraded	23.37	21.56		
0 – 92 d *			118	- 18
g straw degraded	2.12	2.51 **		
% straw degraded	52.95	62.73		
0 – 217 d *			97	3
g straw degraded	3.06	2.96		
% straw degraded	76.38	74.06		

* day 0 was set on June 16, 2010, when the litterbags had been buried
** statistically significant difference to the control (student-t test, α = 0.05, two sided)
1) corresponding to degraded straw in g, formula: (mass loss treatment*100)/mass loss control
2) corresponding to degraded straw in g, formula: ((mass loss control-mass loss treatment)/mass loss control)*100

Coefficients of variation for average straw degradation in the control were 20.72% for 0-29 d; 8.25% for 0-92 d; 7.24% for 0-217 d. Coefficients of variation for average straw degradation in the treatment were 16.37% for 0-29 d; 8.25% for 0-92 d; 3.73% for 0-217 d.

The authors of the study report conclude that the data in Table 9.9.1-2 show that soil residues of flupyradifurone SL 200 G anticipated after long-term use (plateau concentration plus an annual application rate) have no influence on organic matter breakdown after 1, 3 and 7 months.

Remarks

The test meets the validity criteria. Degradation in the control is >60%.

Analysis of the soil samples was performed 8-11 months after sampling. As samples were kept in the freezer this will not have affected the outcome. Measured concentrations were in the range of nominal concentrations.

The residue concentration in soil was measured over 10 cm. This is relevant for the plateau part of the concentration, which was incorporated over 10 cm, but may be worst case for the spray part of the concentration. Usually, for spray applications it is assumed that the initial residues are distributed over a 5 cm layer, therefore it the approach used may be worst case (expressed over 5 cm the endpoint could be doubled). It is however unknown whether the residues in the 10 cm soil cores were evenly distributed or mainly present in the top 5 cm layer, and for the incorporated part of the concentration, 10 cm is relevant. Therefore, the risk assessment should be based on the endpoint mentioned under study conclusion.

Weather conditions were relatively dry in June. This might have influenced soil litter degradation in the first period. However at least 60% soil litter degradation was found at the end of the study in the control plots. Coefficients of variation meet the recommended validity criterion of ≤ 40% for straw degradation in the control plots for data within the first 6 months.
It should be noted that at the second sampling moment a statistically significant difference (18% higher degradation in treatment) was found between control and treatment. This is not considered to be an adverse effect of the treatment. It can be concluded that at a measured initial concentration of 237 µg as/kg dry soil no statistically significant effects were found on soil litter degradation 217 d after treatment. A NOEC ≥ 237 µg as/kg dry soil can be used for risk assessment.

Description

Litterbag study was performed at the Bayer Experimental farm Höfchen, Burscheid, Germany.

Site characteristics

Silty loam, pH 6.47, 1.09% organic carbon (equivalent to 1.9 o.m.), microbial C 477 mg/kg dry soil. Cation exchange capacity 14.5 meq/100 g. Since 2007 the following plant protection products were applied: Basagran DP (bentazon, herbicide), Stomp SC (pendimethalin, herbicide) and Tristar (acetamiprid, insecticide)

Application, concentrations, replicates

Study was conducted in twelve plots, six treatment plots and six untreated plots with a size of 9 m x 9 m = 81 m^2 each. On June 14, 2010, the SL 200 G product was applied on June 14, 2010, at a rate of 150 g as/ha (corresponding to 750 mL test item/ha) in 300 L water/ha and the test item was incorporated into the upper 10 cm soil layer. Assuming a soil bulk density of 1500 L/kg, this procedure leads to a corresponding concentration of 0.1 mg as/kg soil in a depth of 0-10 cm which represents the calculated plateau concentration . Details about calculation of the plateau concentration are not

presented in the litterbag report, plateau concentration was provided by the sponsor. A second application was performed two days later at June 16, 2010, in form of treated summer wheat seed sort 'Chamsin' treated with the FS 480 G product at a rate of 115.37 g as/100 kg seed. The seeding rate of 230 kg seed/ha led to 265 g as/ha. Untreated seed was sown in the control plots. Litterbags (12x22 cm, mesh size 8mm) were filled with 4 g dry wheat straw. In the centre of each plot, 40 litterbags were buried horizontally at a depth of 5 cm with a distance of about 15 cm between each other in each direction. Litterbags were buried on June 16, 2010 after sowing.

Sampling of spray solutions.

Samples of spray solutions were taken before application of the plateau concentration. Samples were not analysed, however, because no need was present, given the clear results of the soil samples.

Soil sampling and analysis.

On July 14, 2007, directly after incorporation of the first application and on June 21, 2010, (5 days after application of annual rate and burying of the litterbags), samples were taken from the soil (each sample consisted of two soil cores per plot). Soil samples of 10 cm depth were randomly taken outside the litterbag area and avoiding a zone of about 1 m from the edge of each plot. Samples were stored frozen until analysis. Soil samples were analysed according to Analytical method 01074/M001 for determination of the active substance. This method is suitable for determination of the active substance (BYI 02960) and the metabolites 6-chloronicotinic acid and difluoroacetic acid using HPLC-MS/MS. Only the active substance will be analysed. LOQ of the method is 5.0 µg/kg for the active substance. Soil samples were kept in the freezer until analysis in March-May 2011.

Removal and processing of litterbags

On three occasions (29, 92 and 217 days after burying (July 15, September 16 and January 19), eight litterbags per plot and sampling time were selected in a randomised procedure. Of the 40 litterbags per plot, eight litterbags were used per sampling time. Litterbags were air-dried to interrupt microbial degradation. Contents were ground and sieved in order to remove any soil for the degraded straw. The remaining mixture of straw and residual mineral soil was dried at a temperature of 35º C for a minimum of 2 hours, before the loss by ignition was determined (30 minutes at 600 ºC).

Calculations and statistical evaluation

Weight difference of the straw between the start of the experiment and the actual sampling time was calculated and used to calculate the degree of degradation. Because separation of litter and soil organic matter is not complete, in accordance with the guidance a correction was applied to correct for possible contribution of soil organic matter to the ash-free dry weight.

Cochran's test was conducted to test for homogeneity of variances and Kolmogorov-Smirnov Test was conducted to test for normal distribution. A Student-t test (two sided, α = 0.05) was performed to determine statistically significant differences between control and treatment. If conditions for homogeneity and/or and normality were not met, data transformation was applied and otherwise the non-parametric Mann-Whitney Pairwise U-test was chosen.

Results

Weather conditions

As no precipitation occurred at June 16 and 17, after the application of the annual rate, plots were irrigated with 6 mm water on June 18. Sum of precipiation at June 20 of 9.5 mm was considered enough for exposure of the soil organisms to the product. Monthly precipitation during test period was 12.2, 88.0, 203.0, 109.0, 60.6, 129.0, 67.5 and 113.9 mm in the months June to January, respectively.

Measured soil concentrations.

Mean measured concentration of flupyradifurone at June 14 (directly after application and incorporation of the plateau concentration) was 94 µg as/kg dry soil in the treated plots, which is 94% of the nominal amount of 100 µg as/kg dry soil (= calculated plateau concentration) (see Table 9.9.1-3). At June 21 (5 days after application of the annual rate) mean measured concentration in the treated plots was 243 µg as/kg dry soil , which is 88% of the theoretical amount 5 days after application of the annual rate and including the plateau rate. These data were corrected for analytical recovery rate of 104%. All calculations assume a soil depth of 10 cm and a soil density of 1.5 g/mL. Concentrations in the samples of the control plots were all <LOQ.

Table 9.9.1-3 . Nominal Degradation of 4 g straw (means of 6 plots) Nominal and analytically verified amount of flupyradifurone, means from 6 plots (copied from report).

	Nominal application rate	
	[µg a.s./kg dry soil]	[g a.s./ha]
Plateau concentration	100	150
Cumulative annual application	177	265
∑	277	415
	Analysed concentrations	
	[µg a.s./kg dry soil]	% of nominal amount
Plateau concentration [soil samples taken after incorporation]	94	94
Plateau concentration + Cumulative annual application [soil samples taken six days after application]	243	88

The degree of degradation was determined by calculating the weight difference of the straw between the start of the experiment and the actual sampling time.

Table 9.9.1-4. Degradation of 4 g straw (means of 6 plots), Table copied from summary of report.

Degradation of 4 g straw:

Means of 4 plots	Control	BYI 02960	% of Control[1)]	% Effect[2)]
0 – 29 d *			100	0
g straw degraded	0.93	0.93		
% straw degraded	23.37	23.37		
0 – 92 d *			99	1
g straw degraded	2.12	2.09		
% straw degraded	52.95	52.35		
0 – 217 d *			105	-5
g straw degraded	3.06	3.20		
% straw degraded	76.38	80.08		

* day 0 was set on June 16, 2010, when the litterbags had been buried
1) corresponding to degraded straw in g, formula: (mass loss treatment*100)/mass loss control
2) corresponding to degraded straw in g, formula: ((mass loss control-mass loss treatment)/mass loss control)*100

Coefficients of variation for average straw degradation in the control was 20.72% for 0-29 d; 8.25% for 0-92 d; 7.24% for 0-217 d. Coefficients of variation for average straw degradation in the treatment 31.42% for 0-29 d; 4.49% for 0-92 d; 6.81% for 0-217 d.
The authors of the study report conclude that the data in Table 9,9,1-3 show that soil residues of BYI 02960 SL 200 G (flupyradifurone) anticipated after long-term use (plateau concentration) plus treated seed application with BYI 02960 FS 480 G (an annual application rate) have no influence on organic matter breakdown after 1, 3 and 7 months.

Remarks

The test meets the validity criteria. Degradation in the control is >60%. Apparently, the same control was used for this study and the previous one (IIIA 10.6.2/01). Analysis of the soil samples was performed 8-11 months after sampling. As samples were kept in the freezer this will not have affected the outcome. Measured concentrations were in the range of nominal concentrations.
The residue concentration in soil was measured over 10 cm. This is relevant for the plateau part of the concentration, which was incorporated over 10 cm, but may be worst case for the spray part of the concentration. Usually, for spray applications it is assumed that the initial residues are distributed over a 5 cm layer, therefore it the approach used may be worst case (expressed over 5 cm the endpoint could be doubled). It is however unknown whether the residues in the 10 cm soil cores were evenly distributed or mainly present in the top 5 cm layer, and for the incorporated part of the concentration, 10 cm is relevant. Therefore, the risk assessment should be based on the endpoint mentioned under study conclusion.
Weather conditions were relatively dry in June. This might have influenced soil litter degradation in the first period. However at least 60% soil litter degradation was found at the end of the study in the

control plots. Coefficients of variation meet the recommended validity criterion of ≤ 40% for straw degradation in the control plots for data within the first 6 months At a measured initial concentration of 243 µg as/kg dry soil no statistically significant effects were found on litter degradation. A NOEC ≥ 243 µg/kg dry soil can be used for risk assessment.

Summary and risk assessment

Two litterbag studies, one similating spray treatment and one seed treatment, both performed in Germany, show no adverse effects on organic matter breakdown after exposure to ca. 0.24 mg BYI 02960/kg soil dw. These tested concentrations are higher than the calculated maximum concentrations of at most 0.160 mg/kg a.s. (measured over 10 cm) for the proposed uses in hops and lettuce ($PEC_{initial}$ expressed over 5 cm + $PEC_{accumulation}$ expressed over 5 (hops) or 20 (lettuce) cm). Therefore the risk to organic matter breakdown is considered to be low.

B.9.8 Effects on soil microbial activity (IIA 8.10, IIIA 10.7)

B.9.8.1 Nitrogen transformation (IIA 8.10.1) and Carbon mineralization (IIA 8.10.2)

STUDY IIA, 8.10.1/01

type of study	:	Inhibition of nitrification in soil	exposure duration	:	28 days
year of execution	:	2009	nominal conc.	:	0.4 and 4.0 mg test item/kg soil d.w.
GLP statement	:	Yes	dosing method	:	Soil was treated with test substance mixed with quartz sand
guideline	:	OECD 216 (2000)	acceptability	:	Acceptable
test substance	:	BYI 02960 a.s., batch BYI02960-01-03 (original batch 2009-000239)	NOEC	:	3.8 mg a.s./kg soil d.w.
a.s. content	:	96.2%			

Methods

The effect of BYI 02960 technical on nitrification in a loamy sand soil was determined under laboratory conditions.

The test soil (properties see Table below, sieved to 2 mm) was taken from an agricultural field that was untreated with agrochemicals and fertilisers for the previous 9 years. Some of the soil properties were not determined on the batch of test soil but on another batch of soil collected within one year from the same plot where the test soil was taken (see footnote (A) under the Table below). This is considered to be acceptable, since texture, CEC and organic carbon content are not considered to change significantly within one year on a plot that is left undisturbed. The soil was used in the test within 1 month from sampling in the field and stored at 4°C prior to use in the test. A batch of soil of 900 g d.w. was treated with the test substance mixed with quartz sand. Lucerne meal was added to a final concentration of 0.5%. Treatment rates were 0.4 and 4.0 mg test item/kg soil d.w.. After mixing, aliquots (300 g d.w.) were dispensed into 500 mL brown glass bottles closed with perforated plastic lids (3 replicate flasks per concentration and for the control). Control soil was treated with quartz sand only. Treated soils were incubated under aerobic conditions at 18-22°C in the dark. Soil moisture was maintained at 40-45% MWHC. On day 0, and after 7, 14 and 28 days, aliquots of 10 g d.w. were removed from each replicate and extracted with 1M KCl. Nitrate, nitrite and ammonia were measured photometrically using an autoanalyser. The soil pH was measured at the start and end of the test and ranged between 6.3 and 6.4.

Table B.9.8.1-01 Properties of the study soil

Parameter	Value
Texture	loamy sand (DIN)[(A)]
% particles >0.063/0.002-0.063/<0.002 mm	10.4/17.4/72.2[(A)]
Maximum water holding capacity (% w/w)	42.65
pH (KCl)	6.3
% organic carbon	1.57[(A)]
Microbial biomass (mg/kg soil)	902 (5.7% of organic carbon)
CEC (meq/100 g soil d.w.)	6.63[(A)]

(A) This property was determined annually on soil from the same plot where the test soil was taken. The value or data shown do not pertain to the batch of test soil but to another batch of soil collected from the same plot where the test soil was taken.

Results

Nitrite was not detected in any sample. Ammonium-N was in the range 11-14 mg/kg on day 0 and 7 and then decreased to 3 and 2 mg/kg after 14 and 28 days, respectively. Nitrate levels and nitrate formation rates are summarised in the Table below. The variation (CV) between nitrate levels of control replicates was ≤10% at any sampling, satisfying the validity criterion of OECD 216 (≤15%). After 28 days, nitrate formation rates differed from untreated soil by 1-2%. The NOEC is 4.0 mg test item/kg soil d.w., equivalent to 3.8 mg a.s./kg soil d.w..

Table B.9.8.1-02 Effect of BYI 02960 technical on nitrification

	nitrate (mg NO_3-N/kg soil d.w.)		
day	control	0.4 mg test item/kg soil d.w.	4.0 mg test item/kg soil d.w.

14-28	24.45	23.97	24.71
	% deviation (nitrate formation rate) from control:		
0-7	-	39	24
7-14	-	0	14*
14-28	-	2	1

* statistically significantly different from control at 5% level.

Conclusion

NOEC 3.8 mg a.s./kg soil d.w..

Guidelines and limitations

The study was conducted according to OECD 216 (2000) and is acceptable. The soil was not adapted to the test conditions prior to treatment, but the adequate increase of nitrate levels in the control over a 28-day period demonstrated that the soil was viable during the test.

STUDY IIA, 8.10.1/02

Characteristics

reference	:	Frommholz U. (2011a)	species	:	Soil microflora
type of study	:	Inhibition of nitrification in soil	exposure duration	:	28 days
year of execution	:	2011	nominal conc.	:	1.33 mg/kg soil d.w.
GLP statement	:	Yes	dosing method	:	Soil was treated with test substance mixed with quartz sand
guideline	:	OECD 216 (2000)	acceptability	:	Acceptable
test substance	:	6-chloronicotinic acid (6-CNA = IC-0); origin batch no. M12653	NOEC	:	1.33 mg/kg soil d.w.
a.s. content	:	98.8%			

Methods

The effect of 6-chloronicotinic acid (6-CNA = IC-0, metabolite of BYI 02960) on nitrification in a silty sand soil was determined under laboratory conditions.

The test soil (properties see Table below, sieved to 2 mm) was taken from an agricultural field that was untreated with agrochemicals and fertilisers for the previous 5 years. The soil was used in the test within about 2 months from sampling in the field and stored at 4°C prior to use in the test. A batch of soil of 900 g d.w. was treated with the test substance mixed with quartz sand. Lucerne meal was added to a final concentration of 0.5%. The treatment rate was 1.33 mg/kg soil d.w.. After mixing, aliquots (300 g d.w.) were dispensed into 500 mL brown glass bottles closed with perforated plastic lids (3 replicate flasks per concentration and for the control). Control soil was treated with quartz sand only. Treated soils were incubated under aerobic conditions at 18-22°C in the dark. Soil moisture was maintained at 42-45% MWHC. On day 0, and after 7, 14 and 28 days, aliquots of 10 g d.w. were removed from each replicate and extracted with 1M KCl. Nitrate, nitrite and ammonia were measured photometrically using an autoanalyser. The soil pH was measured at the start and end of the test and was 7.1 at all samplings.

Table B.9.8.1-03 Properties of the study soil

Parameter	Value
Texture	Silty sand (DIN)
% particles >0.063/0.002-0.063/<0.002 mm	8.0/29.7/62.3
Maximum water holding capacity (% w/w)	39.37
pH (KCl)	7.08
% organic carbon	0.83
Microbial biomass (mg/kg soil)	231 (2.78% of organic carbon)
CEC (meq/100 g soil d.w.)	12.4

Results

Nitrite was not detected in any sample. Ammonium-N was 4, 2, 0.8-1.0 and 0.3-0.4 mg/kg on day 0, 7, 14 and 28, respectively. Nitrate levels and nitrate formation rates are summarised in the Table below. The variation (CV) between nitrate levels of control replicates was ≤7% at any sampling, except on day 7, when it was 32%. The value of 32% does not comply with the validity criterion of OECD 216 (≤15%), but this high value on a single sampling is associated with low nitrate levels on that day (denitrification), and does not invalidate the study. After 28 days, nitrate formation rates differed from untreated soil by 1%. The NOEC is 1.33 mg/kg soil d.w..

Table B.9.8.1-04 Effect of 6-chloronicotinic acid (6-CNA = IC-0, metabolite of BYI 02960) on nitrification

	nitrate (mg NO_3-N/kg soil d.w.)	
day	control	1.33 mg/kg soil d.w.
0	14.74	14.62
7	2.47	1.49
14	16.68	14.85

28	29.02	27.29
	nitrate formation during interval (mg NO_3-N/kg soil d.w./time interval)	
0-7 7-14 14-28	-12.27 14.21 12.34	-13.13 13.36 12.44
	% deviation (nitrate formation rate) from control:	
0-7 7-14 14-28	- - -	7 6 1

It was reported that in the most recent test with the reference item sodium chloride, 16 g sodium chloride/kg soil d.w. had a distinct and long-term (>28 days) influence on microbial mineralization of nitrogen.

Conclusion

NOEC 1.33 mg/kg soil d.w..

Guidelines and limitations

The study was conducted according to OECD 216 (2000) and is acceptable. The soil was not adapted to the test conditions prior to treatment, but the adequate increase of nitrate levels in the control over a 28-day period demonstrated that the soil was viable during the test.

STUDY IIA, 8.10.2/03

Characteristics

reference	:	Schulz L. (2011)	species	:	Soil microflora
type of study	:	Inhibition of respiration in soil	exposure duration	:	28 days
year of execution	:	2011	nominal conc.	:	0.4 and 4.0 mg test item/kg soil d.w.
GLP statement	:	Yes	dosing method	:	Soil was treated with test substance mixed with quartz sand
guideline	:	OECD 217 (2000)	acceptability	:	Acceptable
test substance	:	BYI 02960 a.s., batch BYI02960-01-03 (original batch 2009-000239)	NOEC	:	3.8 mg a.s./kg soil d.w.
purity	:	96.2%			

Methods

The effect of BYI 02960 technical on respiration in a sandy loam soil was determined under laboratory conditions.

The test soil (properties see Table below, sieved to 2 mm) was taken from an agricultural field that was untreated with agrochemicals for the previous 21 years and with organic and inorganic fertiliser for the previous 8 years. It was used in the test within 6 weeks from sampling in the field and acclimated to the test conditions for 7 days prior to treatment. Aliquots (1000 g d.w.) were treated with a mixture of the test substance and quartz sand, mixed and dispensed into 4 L steel flasks. Treatment rates were 0.4 and 4.0 mg test item/kg soil d.w.. Control soil was treated with quartz sand only. Treated soil (3 replicate flasks per concentration) was incubated under aerobic conditions at 20-22°C

in the dark. Soil moisture was maintained at 45-50% MWHC. On day 0, and after 7, 14 and 28 days, aliquots of 100 g d.w. were removed from each replicate, amended with glucose (4 g/kg soil, which exerted a maximum response in a pretest), and oxygen consumption was measured for 12 hours. Evaluation was based on the cumulative oxygen consumption after 12 hours. The soil pH was measured at the start and end of the test and ranged between 6.2 and 6.3. A positive control (Dinoterb, 6.8, 16 and 27 mg/kg soil d.w.) was tested in a field soil about 6 months earlier, and gave the expected response (effects on respiration up to 48%).

Table B.9.8.1-05 Properties of the study soil

Parameter	Value
Texture	sandy loam (USDA)
% particles >0.05/0.002-0.05/<0.002 mm	53/37/10
Maximum water holding capacity (% w/w)	36.67
pH (water)	6.4
% organic carbon	1.39
Microbial biomass (mg/100 g soil)	33.04 (2.38% of organic carbon)
CEC (meq/100 g soil d.w.)	10.0

Results

The results are summarised in the Table below. The variation (CV) between oxygen consumption levels of control replicates was ≤2.2% at any sampling, satisfying the validity criterion of OECD 217 (≤15%). After 28 days, the cumulative oxygen consumption values differed from untreated soil by 0.1-0.9%. The NOEC is 4.0 mg test item/kg soil d.w., equivalent to 3.8 mg a.s./kg soil d.w..

Table B.9.8.1-06 Effect of BYI 02960 technical on soil respiration

Days after application	Control	0.40 mg test item/kg soil dry weight equivalent to 0.3 kg test item/ha		4.00 mg test item/kg soil dry weight equivalent to 3 kg test item/ha	
	O_2 consumption [mg/kg soil d.w./h]	O_2 consumption [mg/kg soil d.w./h]	Deviation from control [%][1]	O_2 consumption [mg/kg soil d.w./h]	Deviation from control [%][1]
0	12.54	12.51	-0.2	12.26*[2]	-2.2
7	11.27	11.28	+0.1	11.27	±0.0

28	9.64	9.66	+0.1	9.56	-0.9

The calculations were performed with unrounded values.
[1] based on O_2 consumption; - = inhibition; + = stimulation
*[2] statistically significantly different to control (Student-t-test for homogeneous variances, 2-sided, $p \leq 0.05$)

Conclusion

NOEC 3.8 mg a.s./kg soil d.w..

Guidelines and limitations0

The study was conducted according to OECD 217 (2000) and is acceptable.

STUDY IIIA, 10.7.1/01

Characteristics

reference	:	Frommholz U. (2010b)	species	:	Soil microflora
type of study	:	Inhibition of respiration in soil	exposure duration	:	28 days
year of execution	:	2010	nominal conc.	:	1.66 and 16.59 µL test item/kg soil d.w.
GLP statement	:	Yes	dosing method	:	Soil was treated with test substance mixed with quartz sand
guideline	:	OECD 217 (2000)	acceptability	:	Acceptable
test substance	:	BYI 02960 SL 200 G (200 g/L SL formulation), batch 2010-001067	NOEC	:	16.59 µL test item/kg soil d.w. (3.335 mg a.s./kg soil d.w.)
a.s. content	:	201.0 g/L BYI 02960			

Methods

The effect of BYI 02960 SL 200 G (200 g/L SL formulation, 201.0 g/L BYI 02960) on respiration in a loamy sand soil was determined under laboratory conditions.

The test soil (properties see Table below, sieved to 2 mm) was taken from an agricultural field that was untreated with agrochemicals and fertiliser for the previous 4.5 years. The soil was stored at 4°C for 3 months prior to use in the test. Batches of soil were then treated with a mixture of the test substance and quartz sand and mixed. Treatment rates were 1.66 and 16.59 µL test item/kg soil d.w.. Control soil was treated with quartz sand only. Aliquots of treated soil (350 g d.w.) were dispensed into 500 mL brown flasks (3 replicate flasks per concentration), that were closed with parafilm and incubated at 18-22°C in the dark. Soil moisture was maintained at 42-49% MWHC. On day 0, and after 7, 14 and 28 days, aliquots of 25 g d.w. were removed from each replicate, amended with glucose (2 g/kg soil, which exerted a maximum response in a pretest), and carbon dioxide production was measured for 12 hours. Evaluation was based on the cumulative carbon dioxide production after 12 hours. The soil pH was measured at the start and end of the test and was 7.0 at all times. The most recent test with a positive control (sodium chloride, 16 g/kg soil d.w.), conducted in an agricultural soil, gave the expected response (long-term (>28 days) effects on carbon transformation).

Table B.9.8.1-07 Properties of the study soil

Parameter	Value
Texture	Loamy sand (DIN)
% particles >0.063/0.002-0.063/<0.002 mm	61/28/10
Maximum water holding capacity (% w/w)	37.55
pH (water)	7.27
% organic carbon	1.46
Microbial biomass (mg/100 g soil)	20.3 (1.39% of organic carbon)
CEC (meq/100 g soil d.w.)	12.9

Results

The results are summarised in the Table below. The variation (CV) between oxygen consumption levels of control replicates was ≤4.3% at any sampling, satisfying the validity criterion of OECD 217 (≤15%). After 28 days, the cumulative oxygen consumption values differed from untreated soil by 5-6%. The NOEC is 16.59 µL test item/kg soil d.w., equivalent to 3.335 mg a.s./kg soil d.w..

Table B.9.8.1-08 Effect of BYI 02960 SL 200 G on soil respiration

Days after treatment	Application rates µL BYI 02960 SL 200 G/kg dry wt. soil				
	control	1.66		16.59	
	mg CO_2 /h/kg dry wt soil	mg CO_2 /h/kg dry wt soil	% of control	mg CO_2 /h/kg dry wt soil	% of control

28	142.5±2.7	133.9±0.5	94 *)	135.4±2.7	95 *)

*) Statistically significant difference to the control (Student t-test, α= 0.05, two-sided)
n.s. No statistically significant difference to the control (t-test, α= 0.05, two-sided)
*w = Statistically significant difference to the control (Welch-t Test for non-homogeneous variances, two-sided, α = 0.05).

Conclusion

NOEC 16.59 µL test item/kg soil d.w. equivalent to 3.335 mg a.s./kg soil d.w..

Guidelines and limitations

The study was conducted according to OECD 217 (2000) and is acceptable. Test flasks were closed with parafilm during incubation, which may hamper air exchange. However, respiration rates of the control on day 7-28 were not remarkably different from those on day 0, hence incubation conditions should have been adequate.

STUDY IIIA, 10.7.1/02

Characteristics

reference	:	Frommholz U. (2010c)	species	:	Soil microflora
type of study	:	Inhibition of nitrification in soil	exposure duration	:	28 days

7-14	1.35	±	0.05	1.28	±	0.26	**5** n.s.w	1.50	±	0.08	**11** n.s.w
14-28	0.99	±	0.09	1.04	±	0.10	**5** n.s.	1.09	±	0.04	**11** n.s.

1) Rate: Nitrate-N in mg/kg dry weight soil/time interval/day, mean of 3 replicates and standard deviation

n.s. = No statistically significant difference to the control (Student-t Test, two-sided, α = 0.05).

n.s.w = No statistically significant difference to the control (Welch-t Test for non-homogeneous variances, two-sided, α = 0.05).

Conclusion

NOEC 16.59 µL test item/kg soil d.w. equivalent to 3.335 mg a.s./kg soil d.w..

Guidelines and limitations

The study was conducted according to OECD 216 (2000) and is acceptable. The soil was not adapted to the test conditions prior to treatment, but the adequate increase of nitrate levels in the control over a 28-day period demonstrated that the soil was viable during the test.

B.9.8.2 Risk assessment

B.9.8.2.1 Risk assessment of the active substance and formulation

Laboratory studies on microbial turnover are available for the active substance BYI 02960, the formulation BYI 02960 SL 200 G, and the metabolite 6-CNA (N-turnover only).
The results indicate that BYI 02960 and BYI 02960 SL 200 G have no adverse impact on microbial C- and N-turnover in soil. NOECs were clearly above the expected exposure in soil.
Overall, it can be concluded that the functioning of soil micro-organisms is not at risk if BYI 02960 SL 200 G is applied according to the recommended use pattern.

The toxicity of BYI 02960 SL 200 G on soil non-target micro-organisms is summarised in the table below.

Table B.9.8.2-01 Effects on soil non-target micro-organisms

Test species	Test design	Ecotoxicological endpoint		Reference
BYI 02960 SL 200 G				
C-cycle	28 d	no influence	16.59 µL prod/kg dws (≡3.335 mg a.s./kg dws)	Frommholz (2010) KIIIA1 10.7.1/01
N-cycle	28 d	no influence	16.59 µL prod/kg dws (≡3.335 mg a.s./kg dws)	Frommholz (2010) KIIIA1 10.7.1/02
BYI 02960				
N-cycle	28 d	no influence	3.8 mg a.i./kg dws	Frommholz (2009) KIIA 8.10.1/01
C-cycle	28 d	no influence	3.8 mg a.i./kg dws	Schulz (2011) KIIA 8.10.2/01
6-CNA				
N-cycle	28 d	no influence	1.33 mg p.m./kg dws	Frommholz (2011) KIIA 8.10.1/02

Risk assessment

According to current regulatory requirements the risk is acceptable, if the effect of the recommended application rate of a compound / product on nitrogen or carbon mineralisation is < 25% after 100 days. In the studies, deviations from the control did not exceed 25% after 28 days, at tested concentrations which are higher than the calculated maximum concentrations of at most 0.160 mg/kg a.s. and 0.012 mg 6-CNA for the proposed uses.

The metabolite 6-CNA was shown to be of general low toxicity for soil organisms (earthworm LC50 >1000 mg/kg, NOEC 95 mg/kg; Hypoaspis NOEC 100 mg/kg; Folsomia NOEC 90 mg/kg). The NOEC of the metabolite 6-CNA for microbial N-turnover was determined to be 111- fold higher than the worst case PEC in soil for 6-CNA. The high margin of safety indicates that microbial C-turnover is not at risk due to formation of 6-chloronicotinic acid in soil.

Similar to 6-chloronicotinic acid the metabolite DFA acid was shown to be of general low toxicity for soil organisms (earthworm LC50 >958 mg/kg, NOEC 59 mg/kg). Assuming a 10-fold higher toxicity of DFA in comparison with to 6-CNA with regard to microbial C- and N-turnover, the risk could still be considered as acceptable.

Furthermore, the metabolites are likely to have been formed in the litterbag studies, in which no risk was identified to organic matter breakdown.

Based on the above, no further studies are required. The risk to soil micro-organisms is considered to be low.

B.9.9 Effects on other non-target organisms (flora and fauna) believed to be at risk (IIA 8.12 and IIA 8.14; IIIA 10.8 and IIIA 10.9)

B.9.9.1 Effects on non-target terrestrial plants (IIA 8.12; IIIA 10.8)

STUDY IIA, 8.12/01

Characteristics

year of execution	:	2010	nominal conc	:	410 g a.s./ha
GLP statement	:	Yes	treatment method	:	Test substance was suspended in water and sprayed on plants
guideline	:	OPPTS 850.4150, OECD 227 (2006)	acceptability	:	Acceptable
test substance	:	BYI 02960 SL 200 g/L (200 g/L SL formulation), batch 2009-001253	ER_{50}	:	>410 g a.s./ha
a.s. content	:	17.0% w/w (199.8 g/L) BYI 02960			

Methods

In a greenhouse screening study (limit test), BYI 02960 SL 200 g/L (SL formulation, 17.0% w/w (199.8 g/L) BYI 02960) was applied to 4 monocot and 7 dicot plant species at a dose rate of 410 g a.s./ha, with a negative (water) control. Applications were made in 200 L water/ha post-emergence of target plants (applications to the plant canopy at the 2-4 true leaf stage (except onion, 1-2 leaf stage) using a calibrated laboratory sprayer. The concentration of BYI 02960 was determined by HPLC/UV in the stock solution and found to be 99% of target. Each treatment was tested in 8 replicate pots containing 4 seedlings per pot. The pot soil was a silt loam soil, pH ($CaCl_2$) 7.31, 1.30% organic carbon. Test conditions were: temperature 10-31°C, daily mean relative humidity 40-100%, at least 16-hour light period. Watering was performed when necessary by bottom irrigation of the pots. Liquid NPK fertiliser was added 7 days after application in the saucers. Assessments of phytotoxicity were made weekly by visual observations using a rating scale of 0 to 100% (comparison to controls) where 0 represented no injury and 100% complete damage. Survival, was recorded weekly and plant height and plant dry weight were recorded 21 days after treatment.

Results

The results are summarised in the Table below. The results of the control group satisfied the guideline requirements (OECD 227, 2006) for all tested species: ≥90% plant survival, 0% phytotoxic damage, (seedling emergence rate was not reported). Visual toxicity was at the most rated as slight (20% effect relative to control), and effects observed included chlorosis, necrosis and stunting. In the absence of any effect on any parameter of >50%, for all parameters and test species the ER50 is >410 g a.s./ha. The NOER is <410 g a.s./ha for oilseed rape and buckwheat, based on a statistically significant

reduction of shoot dry weight, although the effects were small (7-12%). For all other species, the NOER is 410 g a.s./ha.

Table B.9.9.1-01 Effect of BYI 02960 SL 200 g/L on vegetative vigour after 21 days

Species	Survival (% inhibition)	Phytotoxicity	Shoot Length (% reduction)	Shoot Dry Weight (% inhibition)
Dicotyledoneae				
Beta vulgaris	0	0	-2.3	6.5

type of study	:	Seedling emergence	exposure duration	:	21 days
year of execution	:	2010	nominal conc	:	410 g a.s./ha
GLP statement	:	Yes	treatment method	:	Test substance was suspended in water and sprayed on soil
guideline	:	OPPTS 850.4100, OECD 208	acceptability	:	Acceptable
test substance	:	BYI 02960 SL 200 g/L (200 g/L SL formulation), batch 2009-001253	ER_{50}	:	>410 g a.s./ha
a.s. content	:	17.0% w/w (199.8 g/L) BYI 02960			

Methods

In a greenhouse screening study (limit test), BYI 02960 SL 200 g/L (SL formulation, 17.0% w/w (199.8 g/L) BYI 02960) was applied to 4 monocot and 7 dicot plant species at a dose rate of 410 g a.s./ha, with a negative (water) control. Applications were made in 200 L water/ha to the soil containing the seeds, using a calibrated laboratory sprayer. The concentration of BYI 02960 was determined by HPLC/UV in the stock solution and found to be 99-100% of target. Each treatment was tested in 8 replicate pots containing 5 seeds per pot. The pot soil was a silt loam soil mixed with 30% sand, pH ($CaCl_2$) 7.24, 0.63% organic carbon. Test conditions were: temperature 10-31°C, daily mean relative humidity 40-100%, at least 16-hour light period. Watering was performed when necessary by bottom irrigation of the pots. Liquid fertiliser was added to the soil prior to sowing (none thereafter). Assessments of phytotoxicity were made weekly by visual observations using a rating scale of 0 to 100% (comparison to controls) where 0 represented no injury and 100% complete damage. Emergence and survival were recorded weekly and plant height and plant dry weight were recorded 21 days after treatment.

Results

The results are summarised in the Table below. The results of the control group satisfied the guideline requirements (OECD 208) for all tested species: ≥70% emergence, ≥90% plant survival, 0% phytotoxic damage. Visual toxicity was at the most rated as moderate (40% effect relative to control), and effects observed included necrosis, leaf deformation and stunting. In the absence of any effect on any parameter of >50%, for all parameters and test species the ER50 is >410 g a.s./ha. The NOER is <410 g a.s./ha for buckwheat, based on a statistically significant reduction of shoot height and shoot dry weight. For all other species, the NOER is 410 g a.s./ha.

Table B.9.9.1-02 Effect of BYI 02960 SL 200 g/L on seedling emergence after 21 days

Plant Species	Emergence (% inhibition)	Survival (% inhibition)	Phytotoxicity	Shoot Length (% reduction)	Shoot Dry Weight (% inhibition)
Dicotyledoneae					
Beta vulgaris	15.4	6.1	0	1.8	-7.4
Brassica napus	2.8	0	0	-1.3	-10.5
Cucumis sativus	-2.9	0	0	-5.3	-8.6
Fagopyrum esculentum	2.6	0	0 - 40%	**13.8**	**19.7**
Glycine max	8.3	0	0 - 30%	7.0	10.7
Lactuca sativa	-2.6	0	0	2.9	1.1
Lycopersicon esculentum	7.9	0	0 - 20%	-2.0	-16.3
Monocotyledoneae					
Allium cepa	-3.3	-3.4	0	3.6	6.5
Avena sativa	7.5	0	0 - 20%	0.1	-1.0
Lolium perenne	-12.5	0	0	4.6	7.4
Zea mays	7.5	0	0 - 20%	4.2	13.1

Bold figures for shoot dry weight are statistically significant (Pairwise Mann-Whitney-U-test, one sided smaller; p ≤ 0.05)

Conclusion

For all parameters and test species, ER50 >410 g a.s./ha.

Guidelines and limitations

The study was performed according to OECD 208 and is acceptable.

B.9.9.2 Effects on other non-target species (flora and fauna) from available preliminary data (IIA 8.14; IIIA 10.9)

STUDY IIA, 8.14.1/01

Characteristics

reference	:	Malsam O. and Voertse A. (2010)	species	:	*Phaedon cochleariae* (mustard beetle); *Myzus persicae* (green peach aphid); *Nilaparvata lugens* (brown plant hopper); *Aphis gossypii* (cotton aphid); *Bemisia tabaci* (silver leaf whitefly).
type of study	:	Insecticidal efficacy	exposure duration	:	6-10 days
year of execution	:	Not reported	nom. dose	:	4-500 g/ha or 0.0064-0.8 mg/L (microtiter plate testing) or 0.032-20 mg/L (whole plant test)
GLP statement	:	No	dosing method	:	Test item was dissolved in water and sprayed on plant (substrate) or poured on soil.
guideline	:	Not applicable	acceptability	:	Acceptable
test substance	:	BYI02960, batch 2009-000239; difluoroacetic acid; batch BCOO5984-1	Conclusion	:	difluoroacetic acid has no effficacy compared to parent BYI02960
a.s. content	:	BYI02960: 96.2%; difluoroacetic acid: 95.8%			

Methods

The insecticidal activity of BYI02960 and its metabolite difluoroacetic acid were compared in leaf disc (microtiter plate) and in whole plant screening systems.

Microtiter plate testing

Microtiter plate testing employed the following species: *Phaedon cochleariae* (mustard beetle), *Myzus persicae* (green peach aphid) and *Nilaparvata lugens* (brown plant hopper). For Myzus and Phaedon, leaf discs were placed in the cavity of microtiter plates and the microtiter plate cavities were then sprayed with BYI02960 or difluoroacetic acid at rate 4, 20, 100 and 200 g/ha. In case of Myzus, the leaf discs were already infected with Myzus instars at the time of treatment. In case of Phaedon, 2 larvae were placed on the leaf discs after spraying. After 7 days (Phaedon) or 6 days (Myzus), survival was determined. For testing of Nilaparvata, small rice plants were grown in perlite in 10-cm high tubes plugged into each cavity of the microtiter plate. Test compound solutions of BYI02960 or difluoroacetic acid were sprayed onto the plants using a spray concentration of 0.0064, 0.032, 0.16 and 0.8 mg/L, and the plants were infested with plant hoppers afterwards.

Greenhouse test

Greenhouse testing employed the following species: *Myzus persicae* (green peach aphid), *Aphis gossypii* (cotton aphid) and *Bemisia tabaci* (silver leaf whitefly). Testing involved either whole plant spraying (all 3 species) or a soil drench (Myzus only). During whole plant spraying, the test plants (see table below) were sprayed with BYI02960 or difluoroacetic acid using a spray concentration of 0.032, 0.16, 0.8, 4 and (*Bemisia tabaci* only) 20 mg/L. The plants were already infested at the time of treatment. During the drench test (performed on Myzus only), a solution of BYI02960 or difluoroacetic acid in water was poured on the soil of a pot in which a cabbage plant was growing and which was already infested at the time of treatment.

Results

The results are summarised in the tables below. Whereas at the highest test dose or test concentration 90-100% efficacy of BYI02960 was recorded in the 5 insect species, no insecticidal efficacy at all was observed for difluoroacetic acid up to the highest test dose or test concentration. The metabolite difluoroacetic acid does not exhibit any insecticidal efficacy compared to parent BYI02960.

	0.032	0	0		0.032	0

Conclusion

Difluoroacetic acid does not exhibit any insecticidal efficacy compared to parent BYI02960.

Guidelines and limitations

The study is acceptable.

Study IIA 8.16.1/08

Reference	:	Nauen 2013	Test species	:	*Myzus persicae*
Type of study	:	aphid, oral toxicity (2 tests)	Exposure duration	:	24 h
Year of execution	:	2013	Dosing method	:	oral
GLP statement	:	no	Acceptability	:	Not acceptable; may be used as supplemental information provided that the raw data are submitted.
Guideline	:	no specific guideline available	LC50 flupyradifurone	:	0.036 mg as/kg diet / 0.081 pg as/aphid
Test substance and purity	:	Flupyradifurone , purity > 99 % Imidacloprid, purity > 99 %	LC50 imidacloprid	:	0.17 mg as/kg diet / 0.38 pg as/aphid

Description

The effect of imidacloprid and flupyradifurone on the aphid, *Myzus persicae* Sulzer, was assessed in a 24 h continuous feeding test in the laboratory. The test was carried out with an insecticide susceptible strain of the green peach aphid, *Myzus persicae* Sulzer (Homoptera: Aphididae). The strain was maintained on cabbage at 22°C, 50% relative humidity and a photoperiod of 16h (light):8h (dark).

Oral activity of the insecticides was tested with a feeding bioassay using artificial (Parafilm®) double membranes, so-called sachets, as `synthetic leaves´ (Elbert et al., 1991; Nauen et al., 1996). In the described bioassay, the oral LD50-value of imidacloprid against *Myzus persicae* was determined by feeding on an artificial diet and based on the ingestion of a radiolabelled sugar, N-acetyl-D-[14C] glucosamine (Elbert et al., 1991). The uptake of the radiolabelled sugar was measured by liquid

scintillation counting of tissue-solubilized aphids allowed the calculation of the amount of simultaneously ingested imidacloprid based on its concentration in µg/mL (ppm) diet.

The LD50-value obtained earlier for imidacloprid was 0.54 pg/aphid based on a measured LC50-value of 0.24 ppm. The objectives of the current study were (1) to repeat the recently published oral LC50-value of imidacloprid against *M. persicae*, (2) to determine the oral LC50-value of flupyradifurone against *M. persicae* and (3) to calculate its LD50-value based on the repeated imidacloprid data. Each sachet (diameter 2.8 cm) contained 0.15 mL of an aqueous solution of 15% (w/v) sucrose with different concentrations of insecticide covering a potential mortality range from 0 to 100%. Concentrations used were: 0, 0.00256, 0.0128, 0.064, 0.32, 1.6, 8 and 40 mg as/L. A toxic standard was not included in this test. Bioassays were performed twice using three replicates per concentration with seven concentrations per test. Prior to the bioassays the aphids were transferred to small petri dishes for a 4-5 h starvation period. Subsequently 10 to 15 apterous adults (approx. weight 200 µg per aphid) were transferred to one small petri dish (feeding cage) for each concentration and the sachet was stretched over the petri dish. A piece of yellow cellophane was placed over the sachet to enhance the probing activity of aphids. The number of dead aphids was recorded after 2 h. Percentage mortality (dead aphids and those not able to walk in a coordinated manner) was scored after 24 h. Test conditions: 23°C (± 1°C). RH and light conditions were not reported.

Calculations

LC50-values for both compounds were calculated from probit regressions using GraphPad Prism v5.0 software (GraphPad Software, San Diego, California, USA).

The uptake of the radiolabelled sugar measured by liquid scintillation counting of tissue-solubilized aphids allowed the calculation of the amount of ingested imidacloprid based on its concentration in µg/mL diet.

Results

Results are reported in the following tables and figure (copied from the report)

Table 2. Mean aphid mortality (given in %) at different insecticide concentrations tested (24 h).

Compound	Percentage mortality [%] at test concentrations						
	40	8	1.6	0.32	0.064	0.0128	0.00256
Flupyridafurone	100	100	100	99	73	17	3
Imidacloprid	100	100	99	70	27	10	0

Table 3. Log-dose probit-mortality data (24 h) for flupyradifurone and imidacloprid against apterous adults of *M. persicae* in an oral feeding bioassay based on artificial double membranes. Study year 1991 refers to data published by Elbert et al. (1991).

Insecticide	study year	LC-50 value (µg/mL)	95% CL
Flupyradifurone	2013	0.036	0.033 – 0.039
Imidacloprid	2013	0.17	0.12 – 0.23
	1991	0.24	0.078 – 0.72

*Based on data published by Elbert *et al.* (1991) PF-NACHR. Bayer 44, 113 - 136

Figure 1. Dose-response curves obtained for flupyradifurone and imidacloprid against *M. persicae* in an oral feeding bioassay (24 h).

Oral LD50-value for flupyradifurone

Based on the LC50-value of 0.24 µg/mL obtained for imidacloprid in feeding bioassays including radiolabelled N-acetyl-D-[14C] glucosamine, Elbert et al. (1991) calculated an oral LD50-value of 0.54 pg/aphid for imidacloprid. The value is based on the amount of radiolabel taken up at individual imidacloprid concentrations, i.e. the higher the concentration of insecticide the lower the ingested amount of radiolabel due to the onset of symptoms of poisoning preventing aphids from further feeding. Considering the fact that an oral LC50-value of 0.24 µg/mL for imidacloprid corresponded to the uptake of 0.54 pg/aphid and that the oral LC50-value for imidacloprid as reported by Elbert et al. (1991) was confirmed, the author concludes that the LD50-value of flupyradifurone against M. persicae is significantly lower based on its LC50-value of 0.036 µg/mL

Remarks by RMS

A toxic reference is not included in the test. Not all test conditions are reported, RH is missing, light conditions are missing. Raw data are not presented, no information is available on the variability between replicates within the treatments. The number of aphids per treatment is reported to be between 10 to 15. Since no exact numbers are reported, recalculation of the results is impossible. Furthermore it is not clear if the results from this study are realistic and comparable to results deriving from aphids exposed to treated leaves. Thus, there is a number of shortcomings in this report. However, it is acknowledged that there are no harmonised test guidelines for aphids yet. The study indicates that the toxicity of flupyradifurone to aphids is higher than that of imidacloprid. This information could be used in the risk assessment of flupyradifurone, provided that the raw data are submitted so that the results can be recalculated by RMS.

B.9.9.3 Summary and risk assessment

The risk assessment is based on the "Guidance Document on Terrestrial Ecotoxicology", (SANCO/10329/2002 rev2 final, 2002). It is restricted to off-field situations, as non-target plants are non-crop plants located outside the treated area. Spray drift from the treated areas may lead to residues of a product in off-crop areas. Exposure is not relevant for glasshouse uses.

In the case of a non-herbicide, screening results and/or Tier 1 studies give first information about the likelihood for terrestrial plant effects. The risk can be considered acceptable if there are no data indicating more than 50% phytotoxic effect at the maximum application rate.

Seedling emergence (Gosch (2010), KIIIA1 10.8.1.3/01) and vegetative vigour studies Gosch (2010), KIIIA1 10.8.1.2/01) have been conducted with BYI 02960 SL 200 G following OECD testing guidelines 208 and 227, respectively (see Annex Points IIIA1 10.8.1.3 and 10.8.1.2). Each study included 11 species which were tested at the maximum application rate of 410 g a.i./ha.
In the case of BYI 02960 SL 200 G neither the tier 1 seedling emergence nor the vegetative vigour studies showed phytotoxic effects >50% at the maximum application rate of 410 g a.i./ha. Therefore, the ER50 values are set at >410 g a.s./ha.

For the proposed field uses in hops and lettuce, the following scenario is used to describe the exposure to non-target plants:

off-field exposure= Application rate * MAF * drift factor

For the MAF and drift factor, similar assumptions are made as for the off-field risk assessment for non-target arthropods.
As the proposed uses of BYI 02960 SL 200 formulation involves one application only, the multiple application factor (MAF) is 1. Drift values are 19.33% for hops (3 m distance) and 2.77% for lettuce (field crops, 1m distance).

The calculated exposure for the respective uses and the TER values are given in Table B.9.9.3-01.

Table B.9.9.2-01 Exposure values and TERs for non-target plants

Crop	Max. single dose [g a.s./ha]	number of applications	MAF	Drift [%]	Exposure [g a.s./ha]	ER_{50} [g a.s./ha]	TER	Trigger
hops	150	1	1	19.33	30	>410	>14	5
lettuce	125	1	1	2.77	3.5	>410	>118	5

1: drift in vegetables, > 50 cm.

For both uses, the TERs are above the trigger of 5. A low risk for non-target plants is expected.

B.9.10 Effects on biological methods for sewage treatment (IIA 8.15)

B.9.10.1 Effects of the active substance

STUDY IIA, 8.15/01

Characteristics

reference	:	Caspers C. (2010)	water solubility	:	3000-3200 mg/L at pH 4-9 & 20°C
type of study	:	Activated sludge respiration inhibition test	exposure duration	:	3 hours
year of execution	:	2010	nominal conc.	:	100, 180, 320, 560 and 1000 mg test item/L
GLP statement	:	Yes	treatment method	:	Test substance was stirred in water for 15 hours and added to test flasks
guideline	:	OECD 209, EC C.11	acceptability	:	Acceptable
test substance	:	BYI 02960; technical, batch 2009-000239	3-hour EC50	:	>962 mg a.s./L
purity	:	96.2%			

Methods

The effect of BYI 02960 technical on the rate of respiration of bacterial populations from activated sludge was determined after a contact time of 3 hours. The sludge was obtained from the municipal sewage treatment plant of Cologne-Stammheim, Germany (final concentration in test 0.8 g solids/L). BYI 02960 technical was added to the test vessels with 130 mL of water and the mixtures were stirred for 15 hours at ambient temperature. Thereafter synthetic nutrient medium and activated sludge suspension (pH 7.5) were added, and water was added to a total volume of 250 mL (test concentrations 100, 180, 320, 560 and 1000 mg test item/L). Each treatment was tested in one flask, the untreated control was tested in 2 flasks. The test solutions were aerated for 3 hours at 20°C. At the end of the 3 hour contact time, the oxygen consumption was measured.

Results

The concurrently determined EC50 of the reference product 3,5-dichlorophenol (8.7 mg/L) was in the acceptable range of 2 to 25 mg/L (OECD 209 (2010)). The respiratory rates in the two replicate control flasks were 24.9 and 26.0 mg O_2/L/hour, hence satisfying the criteria of OECD 209 (2010): CV <30% and >20 mg O_2/L/hour.

At 100, 180, 320, 560 and 1000 mg test item/L, respectively, the inhibition percentage of the respiratory rate was 0, 0, 0, 8.6 and 23.3%. The 3-hour EC50 is >1000 mg test item/L, equivalent to >962 mg a.s./L.

Conclusion

3-hour EC50 >962 mg a.s./L.

Guidelines and Limitations

The study was performed according to OECD 209 and is acceptable.

B.9.10.2 Risk assessment

Emission of flupyradifurone to sewage treatment plants may occur following the proposed use of Sivanto in glasshouses. The expected concentration in the STP is not calculated because EU harmonised guidance is lacking. However, based on the results of the activated sludge respiration test, which obtained an EC_{50} > 962 mg a.s./L, no effect on biological methods of sewage treatment are expected.

B.9.11 POP/PBT/vPvB assessment

Assessment of the properties with regard to the POP criteria of the Stockholm Convention or the vPvB and PBT criteria				
Active substance flupyradifurone				
		POP/vPvB	PBT	
Persistence	DT_{50} water	> 2 months (60 d)	> 120 d	yes water/sed: DT50w max 123.8
	DT_{50} soil	> 6 months (180 d)	> 120 d	yes lab: DT50 max 235 field: DT50 max 251
	DT_{50} sediment	> 6 months (180 d)	> 120 d	yes water/sed: DegT50system max 285
	Conclusion: P criterion fulfilled?			yes → P
Potential for extensive trans-port into the environment	$DT_{50\ air}$ (direct and indir-ect phototrans-formation)	> 2 d / --	--	no
Bioaccumulation	BCF	> 5000	> 2000	no
Toxicity	NOEC aquatic organisms	--	< 0.01 mg/L	no NOEC *C. riparius* 0.010 mg/L

The active substance flupyradifurone does not fulfil all the POP/vPvB criteria. The active substance does not fulfil all the P and B criteria completely (B not applicable) and should not be classified as a potential PBT active substance.

B.9.12 References relied on

Scientific peer reviewed open literature.

The following data requirements and open points were identified in the evaluation table for ecotoxicology:

Open point 5.18 RMS to present an evaluation of the literature review completed by the applicant in an addendum. See reporting table 5(79)
Data requirement 5.5 Applicant to provide a search of the scientific peer-reviewed open literature relevant to the scope of the application, dealing with side-effects on health, the environment and non-target species and published within the last 10 years before the date of submission of dossier, being conducted and reported in accordance with the Guidance of EFSA on the submission of scientific peer-reviewed open literature for the approval of pesticide active substances under Regulation (EC) No 1107/2009 (EFSA Journal 2011;9(2):2092) for the aqueous photolysis metabolites BYI 02960-succinamide and BYI 02960-azabicyclosuccinamide that do nor appear to have been included in the available literature review. See reporting table 5(79)

The applicant has provided a search of the scientific peer-reviewed open literature for flupyradifurone and metabolites (including the aqueous photolysis metabolites BYI 02960-succinamide and BYI 02960-azabicyclosuccinamide). They provide a list of bibliographic databases searched, the search input parameters and the search results. They also provide the following summary of their literature review:

"*A literature review was conducted for flupyradifurone and its metabolites according to the requirements of Regulation EC 1107/2009.*
The total number of literature findings within the last ten years before submission were 342, all referring to two metabolites. A large number of keywords, grouped by the categories "health", "environment" and "non target species" has been used as a text mining filter. From the total of 342 references, 136 publications were identified which gave a matching overlap with one or more of the keywords used. All 342 references were reviewed by scientific experts and categorized.
The filter was merely tested, and improved, as a tool to be applied in future literature reviews for other compounds. From those references which could not be allocated to one of the categories "health", "environment" or "non target species", none was identified by the scientific experts to provide relevant information for regulatory purposes, i.e. no false negative findings were identified.
None of the studies was considered relevant as defined by the EFSA Guidance document on 'submission of scientific peer-reviewed open literature for the approval of pesticide active substances

under Regulation (EC) no. 1107/2009', i.e. as "dealing with side-effects on health, the environment and non-target species".
In the area of toxicology, only one publication was evaluated as "relevant". Fortunately this publication was already known and the result was therefore already assessed and fully integrated in the supplementary dossier Therefore, no reference had to be discussed separately in the dossier, as all risk assessments remained fully valid after consideration of all references.
In conclusion, no information was identified which was considered to have an impact on an endpoint or would result in the need to adapt a risk assessment in the flupyradifurone dossier."

Remarks RMS

A literature search and review was provided by the applicant. The search has been conducted in line with the EFSA guidance. Of all identified papers (342) the relevant ones (136) have been selected by the applicant in a transparent way using a text mining filter. The applicant provided a general justification for evaluating the relevant papers. As no study-by-study justifications were given the RMS can not properly verify whether the 136 relevant papers were correctly evaluated in terms of reliability/validity/acceptability for regulatory use. The one study that was considered relevant by the applicant is evaluated in the DAR (B.6). RMS notes that flupyradifurone is a new active substance worldwide. Therefore, public literature is not expected to be an important new information source for the active substance itself.

KIIIA1 10.5.2 /04	Jans, D.	2010	Chronic toxicity (ER50) of BYI 02960 SL 200 (g/L) to the rove beetle Aleochara bilineata Gyll. (Coleoptera: Staphylinidae) under extended laboratory conditions Bayer CropScience, Report No.: CW09/072, Edition Number: M-384433-01-2 Date: 2010-06-30 GLP/GEP: yes, unpublished	Yes	BCS
KIIIA1 10.5.3 /01	Jans, D.	2010	Toxicity to the parasitoid wasp Aphidius rhopalosiphi (DESTEPHANI-PEREZ) (Hymenoptera: Braconidae) in an extended laboratory test (under semi-field conditions aged residues on Zea mays) BYI 02960 SL 200 (g/L) Bayer CropScience, Report No.: CW10/018, Edition Number: M-396372-01-2 Date: 2010-11-30 GLP/GEP: yes, unpublished	Yes	BCS
KIIIA1 10.5.3 /02	Schwarz, A.	2010	Effects of BYI 02960 SL 200 (g/L) on the predatory bug Orius laevigatus extended laboratory study - aged residue test IBACON GmbH, Rossdorf, Germany Bayer CropScience, Report No.: 58691053, Edition Number: M-394033-01-2 Date: 2010-10-28 GLP/GEP: yes, unpublished	Yes	BCS
KIIIA1 10.5.4 /01	Aldershof, S.; Bakker, F.	2012	A field study to assess the effects of BYI 02960 SL 200 g/L on the non-target, surface- and plantdwelling, arthropod fauna of a grassland habitat (off-crop) in The Netherlands during summer MITOX Consultants, Amsterdam, The Netherlands Bayer CropScience, Report No.: B154FFN, Edition Number: M-425092-01-2 Date: 2012-02-17 GLP/GEP: yes, unpublished	Yes	BCS

Annex point / reference number	Author(s)	Year	Title Source (where different from company) Company name, Report No., Date, GLP/GEP status (where relevant), published or not	Data protect. claimed	Owner
KIIIA1 10.5.4 /02	Aldershof, S.; Bakker, F.	2012	A field study to assess the effects of BYI 02960 (SL 200 g/L) on the non-target, surface- and plant-dwelling arthropod fauna of a grassland habitat (off-crop) in SW France during summer MITOX Consultants, Amsterdam, The Netherlands Bayer CropScience, Report No.: B153FFN, Edition Number: M-425080-01-2 Date: 2012-02-17 GLP/GEP: yes, unpublished	Yes	BCS
Q 15 /01 (relevant for KIIIA 10.5.4)	Neumann, P.	2014	Extended summaries of the non-target arthropod off-crop field studies conducted for flupyradifurone SL 200 (including the evaluation of the EU RMS) Bayer CropScience, Report No.: M-496127-01-1, Edition Number: M-496127-01-1 Date: 2014-09-09 GLP/GEP: n.a., unpublished	Yes	BCS
KIIIA1 10.6.2 /01	Leicher, T.	2010	BYI 02960 SL 200 G: acute toxicity to earthworms (Eisenia fetida) tested in artificial soil with 5 percent peat Bayer CropScience, Report No.: LRT/RG-A-143/10, Edition Number: M-397720-01-2 Date: 2010-12-14 GLP/GEP: yes, unpublished	Yes	BCS
KIIIA1 10.6.3 /01	Leicher, T.	2010	BYI 02960 SL 200 G: Effects on survival, growth and reproduction on the earthworm Eisenia fetida tested in artificial soil Bayer CropScience, Report No.: LRT-RG-R-76/09, Edition Number: M-392964-01-2 Date: 2010-10-21 GLP/GEP: yes, unpublished	Yes	BCS
KIIIA1 10.6.4 /01	Menke, U.	2012	BYI 02960 SL 200 G: Effects on the earthworm fauna of a grassland area within one year Bayer CropScience, Report No.: MNU/RG-F-8/12, Edition Number: M-426607-01-1 Date: 2012-03-07 GLP/GEP: yes, unpublished	Yes	BCS
KIIIA1 10.6.6 /01	Frommholz, U.	2009	BYI 02960 SL 200 G: Influence on the reproduction of the collembola species Folsomia candida tested in artificial soil with 5 % peat Bayer CropScience, Report No.: FRM-COLL-75/09, Edition Number: M-359728-01-2 Date: 2009-12-02 GLP/GEP: yes, unpublished	Yes	BCS

Annex point / reference number	Author(s)	Year	Title Source (where different from company) Company name, Report No., Date, GLP/GEP status (where relevant), published or not	Data protect. claimed	Owner
KIIIA1 10.6.6 /02	Kratz, M.-A.	2009	BYI 02960 SL 200 G: Influence on mortality and reproduction on the soil mite species Hypoaspis aculeifer tested in artificial soil with 5 % peat Bayer CropScience, Report No.: KRA-HR-19/09, Edition Number: M-358752-01-2 Date: 2009-11-10 GLP/GEP: yes, unpublished	Yes	BCS
KIIIA1 10.7.1 /01	Frommholz, U.	2010	BYI 02960 SL 200 G : Determination of effects on carbon transformation in soil Bayer CropScience, Report No.: FRM-C-116/10, Edition Number: M-395469-01-2 Date: 2010-11-23 GLP/GEP: yes, unpublished	Yes	BCS
KIIIA1 10.7.1 /02	Frommholz, U.	2010	BYI 02960 SL 200 G: Determination of effects on nitrogen transformation in soil Bayer CropScience, Report No.: FRM-N-148/10, Edition Number: M-396112-01-2 Date: 2010-11-29 GLP/GEP: yes, unpublished	Yes	BCS
KIIIA1 10.8.1.2 /01	Gosch, H.	2010	BYI 02960 SL 200 g/L - Effects on the vegetative vigour of eleven species of non-target terrestrial plants (Tier 1) Bayer CropScience, Report No.: VV 10/002, Edition Number: M-397734-01-2 Date: 2010-12-14 GLP/GEP: yes, unpublished	Yes	BCS
KIII A, 10.8.1.3 /01	Gosch, H.	2010	BYI 02960 SL 200 g/L - Effects on the seedling emergence and growth of eleven species of non-target terrestrial plants (Tier 1) Bayer CropScience, Report No.: SE10/001, Edition Number: M-397727-01-2 Date: 2010-12-14 GLP/GEP: yes, unpublished	Yes	BCS

European Commission

Flupyradifurone

VOLUME 4

ANNEX C

Rapporteur Member State: The Netherlands

November 2014

~~January 2014~~

Draft Assessment Report and Proposed Decision of the Netherlands prepared in the context of the possible approval of flupyradifurone under Regulation (EC) 1107/2009
